Early in 1854, symptoms of neglect for the interests of the colony, and an evident leaning towards Victoria, on the part of the imperial government, showed that New South Wales did not hold the first place in the official mind at the colonial office amongst the Australian group of colonies. This was practically exemplified in the month of March, when it was announced that orders had been received for the removal of the commander of the forces and the entire military staff from Sydney to Melbourne. The colonists took umbrage at this, and denounced the measure "as a piece of gross injustice, and of marked disregard to the claims for priority, which the acknowledged metropolis of the Australian colonies undoubtedly possesses." They looked upon it as the precursor of still greater changes on the appointment of Sir Charles Hotham to the lieutenant-governorship of Victoria, who was expected to be made governor-general, on Sir Charles Fitzroy being succeeded by Sir William Denison from Van Diemen's Land. During this year the imports of merchandise far exceeded the demand, and there was the same glut in the markets of Sydney as at Melbourne. Considerable commercial distress was the result. Those among the merchants and shopkeepers who could not hold out until the goods were worked off, were obliged to succumb, and many failures happened in consequence. There was a marked increase of internal trade carried on between Sydney and the northern districts of the colony around Moreton Bay. No workable gold fields had yet come to light, and yet the exports of produce averaged half a million annually. A movement had taken place amongst the settlers in that distant part of the colony to petition the home government for separation from the parent settlement, as in the case of Port Phillip. But this proposition fell to the ground for want of support within the walls of the legislative assembly. That body had likewise discussed the proposition submitted to them by the government, of forming a new constitution for the colony. Like their neighbours, they had given it as their opinion that nominee members should not form an element of the future assemblies, that there should be a lower house similar to the present, and that an upper house be formed by members possessed of a high money qualification. The general affairs of the colony were in a progressive state towards the close of the year; and the tranquillity of the colony presented a contrast to the rebellious condition of Victoria.

Australia. New South Wales.

Topography. Pl. XXVI.

The colony of New South Wales, until the separation of Port Phillip, comprehended within its present boundary only nineteen counties, namely, Cumberland, Camden, St Vincent, Northumberland, Gloucester, Durham, Hunter, Cook, Westmoreland, Argyle, Murray, Brisbane, Bligh, Phillip, Wellington, Roxburgh, Bathurst, Georgiana, and King. The act which erected that district into an independent province, divided the squatting districts S. and N. of the nineteen counties into forty-nine more, namely, Cowley, Buccleuch, Dampier, Beresford, Wallace, Wellesley, Auckland, Macquarie, Hawes, Parry, Buckland, Pottinger, Inglis, Vernon, Dudley, Sandon, Raleigh, Gresham, Clarence, Richmond, Rous, Buller, Ward, Churchill, Stanley, Cavendish, Canning, March, Lennox, Fitzroy, Aubigny, Merivale, Bentinck, Drake, Clive, Gough, Hardinge, Darling, Napier, Gowen, Gordon, Monteagle, Clarendon, Selwyn, Lincoln, Ashburnham, Harden, Wynyard, Goulburn, making in all sixty-eight counties. They extend along the coast about 800 miles, and into the interior about 180 miles. Not only is the whole of that extent of country thoroughly explored and occupied by the settlers, but a trigonometrical survey has been nearly finished; so that the map of New South Wales, in the tracing of its mountains and streams, is assuming that detailed appearance presented by the ordinary maps of Europe.

General aspect of the country.

The general aspect of the country in the interior may be called mountainous or hilly; and covered with an open forest occasionally intersected by brushwood thickets. On the sea-coast, along which the great South Pacific Ocean rolls its tremendous surge, it is bold and rugged, and for five or six miles from the coast it wears a bleak and barren aspect; presenting a soil composed mainly of drift sand, scantily covered with stunted trees and shrubs. But this would give an inadequate and unfair description of the whole; for, like the entire island itself, it is the most chequered country of good and bad land in the world. In the interior, rich and fertile valleys lie in the lap of these ranges, such as the Vale of Clywd, to the westward of the Blue Mountains; and extensive undulating grassy plains, like those of Maneroo and Liverpool plains, are approached through a barren and rocky region. On the coast, also, the romantic and fertile district of Illawarra in Camden, a ma-

Australia. New South Wales.

ritime county to the S. of Cumberland, is surrounded by a desolate region of barren hills; and the rich valley of the Hunter River system of waters contrasts with the Clarence and Richmond to the northward. Again, the tropical aspect of the jungles and mangrove swamps of Moreton Bay are so different from the verdant prairies of the Darling downs almost destitute of timber, and with few streams, that the traveller approaching the former from the E. and the latter from the S. could scarcely imagine them to be in the same country within 1000 miles of each other; and yet they are contiguous. To give, therefore, the most succinct view of this territory, it would be necessary to describe each district. As our limits, however, prevent this, it will suffice to give the general character of the two great watersheds from the main range or cordillera which divides the eastern from the western streams. From Mount Kosciusko, 6500 feet high, —the highest of the Australian Alps—situated 120 miles inland from Cape Howe, this range of mountains extends in a northerly direction through the whole extent of the colony to the boundary line at Moreton Bay. The rivers which flow to the eastward have 100 outlets on the sea-coast; descending rapidly from their sources—which are on the average under 80 miles in a straight line from their outlets, and 1800 feet above the level of the sea; passing through a hilly region in a tortuous course. The streams flowing to the westward, deriving their sources from 1000 fountainheads, flow through extensive valleys and plains, describing a multitude of ramifications until they either join in one great river 400 miles from their sources, or lose their waters in extensive marshes. The land on the eastern streams is for the most part inferior in quality, both for agriculture and pasture, to that on the western streams. While the latter enjoys a cooler climate than the former, it consists also of a rich black and dry soil, covered with luxuriant herbage, interspersed here and there with valleys, open woodlands, and forests, whereon the herds and flocks of the settlers now graze, and a busy population of gold-seekers are digging up the ground for the hidden treasure. Again, on the river banks which face the rising sun, the orange, the banana, and the vine grow abundantly; and the day is not far distant when wine, tobacco, and cotton will be among the staple exports from this coast. Between the girdle of the coast and the mountain range, the country extends in gentle undulations for many miles, clothed with stately forests, which, where cultivation has made progress, are diversified with farms and tenements, and intersected by broad and excellent turnpike roads. Lastly, the coast is indented with numerous bays and harbours, unsurpassed for security and extent by any in the world; while the noble city of Sydney, with its classic buildings, and 100 other towns and villages, are visible throughout the length and breadth of the land; giving that air of dignity and of settled comfort to its inhabitants which belongs essentially to older countries, and which is not observable in the aspect of the newer colonies in Australia.

Soil and climate.

Australia being situated in the opposite hemisphere to Britain, its seasons are exactly the reverse of ours. July is the middle of winter, and January of summer. The festivities of Christmas and of the new year are celebrated here, not, as in the old country, with doors and windows shut, and a cheerful fire to dispel the winter cold, but amid the oppression and heat of summer, with doors and windows thrown open to invite the refreshing breeze. We no longer hear in this Australian climate of the "gentle south wind," nor of "rude Boreas, blustering railer." The north is here the region of heat, as the south is of cold. The summer extends from the 1st of December to the end of February; and the mean heat during these three months is about 80° at noon. This great heat is tempered along the coast by the sea breeze, which sets in regularly about nine in the morning, and blows with considerable force till about six or seven in the evening, when it is succeeded by a land-breeze from the mountains, which varies from W.S.W. to W. In very hot days the breeze often veers round from N. to S., and blows a hurricane. The hot winds to which the country is exposed, especially in the interior, three or four times every summer, blow from the N.W., like a current of air issuing from a heated furnace, raising the thermometer to 100° in the shade, and to 125° when exposed to their influence. They imbibe their heat from the great central desert alluded to in the article AUSTRALASIA. They are generally succeeded by a cold southerly squall, and by a thunder-storm and rain, which cools the air. The spring months are September, October, and November. In the beginning of September the nights are cold, but the days clear and pleasant. The thermometer varies from 60° to 70° towards the end of the month; and light showers occasionally prevail, with thunder and lightning. The days become gradually warmer, and in October the hot and blighting winds from the north begin to be apprehended. The three autumn months are March, April, and May. The first is rainy, and more fertile in floods than any other in the year. Towards the end of April the weather becomes perfectly clear and serene. The thermometer varies from 72° at noon to 60°, and in the mornings is as low as 52°. During May the thermometer varies from 50° at sunrise to 60° at noon, with a perfectly cloudless sky. During the three winter months of June, July, and August, the mornings and evenings are cold; hoar frosts are frequent, and become more severe in advancing into the interior. At Sydney the thermometer is rarely below 40°; at Parramatta it is frequently as low as 27° in the course of the winter. As the land rises from the ocean, the temperature declines. The winter at Bathurst, where snow falls in its season, is much colder than on the sea-shore. On the loftiest hills heavy falls of snow take place during the winter, and it remains for many days on their summits; and some high ranges penetrate the level of perpetual snow. In the valleys, however, the snow does not lie. The greatest defect in the climate is the prevalence of periodical droughts, in consequence of which the vegetation is parched, a general failure of the crops follows, and numbers of the cattle perish. Although in general a large quantity of rain falls throughout the year, yet the colony has hitherto been subject to severe periodical droughts. A drought took place in 1826, which continued till 1829; another in 1839; and more recently, in 1849-50, another severe drought took place, which occasioned general distress in the colony. The climate is, however, on the whole highly salubrious and agreeable. Out of a community of 1200 persons, it has been known that only five or six have been sick at a time; and at some of the military stations, seven years have elapsed without the loss of a man. The fact is now pretty well ascertained, that its dry healing influence is beneficial in pulmonary consumption. Hydrophobia is happily unknown, although dogs abound. The Asiatic cholera has never visited these shores: dysentery, however, is prevalent amongst newly-arrived people. Cases of organic lesion of the heart are frequent, and cause the majority of sudden deaths. Ophthalmia, too, is not uncommon in the districts of the Hunter and Moreton Bay. The only instance of an epidemic visiting this country was in 1849, when the influenza carried off a number of the inhabitants; yet notwithstanding these facts, and the assertions of inexperienced emigrants, the climate of New South Wales has been pronounced by good authorities to be one of the most healthy and salubrious on the face of the earth. As the aspect of the country, however, possesses no general feature whereby to describe its character, so the varieties of soil and climate in New South Wales cannot be classed under one general head. Not only are the warmer localities and poorer soils on the eastern shed of waters greatly different from the rich lands and cooler atmosphere on the western streams, but these

Australia. New South Wales.

Australia. New South Wales.

again are diversified by the variations of latitude. The territory of New South Wales, as before stated, extends between the parallels of 26° and 38° S. Lat., or about 800 statute miles; hence it will be naturally supposed to possess the graduated influence of solar heat at the sea-level alone to cause local variations of temperature. And this, added to the higher altitudes of the country inland, produces a variety of meteorological phenomena which materially affect the indigenous as well as the imported subjects of the animal and vegetable world. In ordinary parlance, therefore, it is as erroneous to speak of the climate of New South Wales generally as if there were one uniform recurrence of weather throughout that territory, as it would be to designate as one description of climate the varied weather which simultaneously occurs between Switzerland and the African shores of the Mediterranean. For there is as great a difference in the weather which happens in the regions between the Maneroo plains, elevated 2000 feet above the level of the sea, and situated at the base of the Australian Alps, covered with snow, and the intertropical district of Moreton Bay, within whose waters turtle abound; these being the extreme S. and N. boundaries of the colony. In the former region, the gooseberry and the apple flourish in the frigid atmosphere; in the latter the pine-apple and the banana grow rich and luxuriantly in the open air. While the Maneroo settlers rear coarse-woolled sheep upwards of 100 lb. in weight, the Moreton Bay squatters have the finest-woolled merinos under 50 lb.: and their proprietors may be distinguished in the streets of Sydney, which lies midway between them, by the ruddy English complexion of the one, and the sallow Indian face of the other.

Vegetable produce.

The agricultural products of New South Wales comprehend all the cereals grown in Europe, and many which are confined to tropical countries. Of the former, wheat, barley, oats, and rye, with hay, lucerne, and other kinds of fodder for cattle and horses, comprise the farmer's list; of the latter, maize, tobacco, and lately cotton, have been profitably cultivated. The barren soil, however, around the environs of Sydney, renders the inhabitants of that city and its suburbs dependent upon Van Diemen's Land for their supplies of grain. The Hunter River and other districts being subject to droughts, the cultivation of cereal crops is precarious. So devastating were their effects in early times, that the government had siloes on the Egyptian plan sunk on an island (Cockatoo) in Sydney harbour, and filled with grain in case of famine. In the above-named district, a large quantity of maize or Indian corn is produced, mainly for the food of horses, pigs, and poultry. In 1852, there were 152,057 acres of land under cultivation, exclusive of vineyards. The culinary vegetables common in this country thrive admirably in New South Wales; such as potatoes, cabbages, carrots, parsnips, turnips, peas, beans, cauliflowers, lettuces, cucumbers, and pumpkins, besides sweet potatoes, yams, and plantains. Many of the former attain to greater perfection than in Europe, as the cauliflower and the brocoli; and green peas are to be had in Sydney all the year round; whilst a few degenerate, such as the bean. The colony is famed also for the abundance and variety of its fruits. Peaches, apricots, nectarines, loquats, oranges, grapes, pears, plums, figs, pomegranates, raspberries, strawberries, mulberries, and melons of all sorts, attain the highest degree of maturity in the open air. Added to these, the northern districts produce pine-apples, bananas, guavas, lemons, citrons, and other tropical fruits. Excepting on the high mountain districts to the westward and southward of Sydney, the climate is not so congenial to the production of northern fruits, such as the apple, the currant, the gooseberry, and the cherry. Grapes of the finest quality are produced in the colony, not only for the table, but for the manufacture of wine. Upwards of 1000 acres of vineyards are laid out in the most complete manner for the culture of the vine, which in 1852 produced 84,843 gallons of wine, and 1641 gallons of brandy. The Australian tobacco, both from its quantity and its quality, is now fast superseding the importation of American tobacco. In 1852, 12,530 cwts. were manufactured in the colony. The olive-tree, likewise, grows luxuriantly, and a superior sample of oil has been produced. The cultivation of cotton upon the Brisbane River at Moreton Bay realized to the experimental planters in 1852 a clear profit of L.12 per acre. Altogether, the capabilities of this varied soil and climate for the production of the universal staple commodities of cotton, tobacco, and wine, are unlimited. All that the colony requires to raise them in sufficient abundance for her own consumption and foreign export, is capital and labour. Already much has been done by the enterprizing colonists in this direction. While we write, Mr Hickey of Osterley, Hunter's River, has produced before the wine-tasters in the London Docks samples of his vintage of light wines, which have been pronounced equal to the best hock and Sauterne imported into London; while a parcel of cotton has been sold in Manchester as high as 2s. 6d. per lb. from the Moreton Bay district; and a company is now forming to introduce the cultivation of the cotton plant there by free labourers, so that the Manchester cotton manufacturers may be independent of the American planters, which may ultimately tend to abolish negro slavery throughout the United States.

Australia. New South Wales.

Animal produce.

Of the indigenous animals in Australia, we have given some account in the preceding article. We shall notice here, therefore, more particularly the capabilities of the country for rearing imported stock, poultry, &c., and those birds and fishes used as food by the colonists. The extent of pasture land within New South Wales occupied by the herds and flocks of the settlers is not far short of 50,000 square miles; upon which there were grazing at the end of 1852, 116,397 horses, 1,375,257 horned cattle, and 7,396,895 sheep. The climate is peculiarly congenial to the growth and increase of these animals. The breed of horses, both thorough-bred, and half-bred hacks, is such, that they are exported to India for the purpose of supplying the East India Company's cavalry and artillery. The horned cattle are, in many instances, of a gigantic size, weighing from 13 to 14 cwt. The sheep are mostly of the fine merino breed; but, on the elevated downs, the Leicester breed crossed with the merino, thrive best, and give a heavier carcase, with a greater quantity of coarse wool than the pure-bred stock. From the dry nature of the herbage, the mutton and beef has not that rich flavour which is so much prized in English-fed cattle and sheep. Swine are abundant, the number of pigs in 1852 amounting to 65,510. They are mostly fed upon the "graves" of the tallow-melter; which neither produces as sweet pork nor such solid flesh as the ordinary methods of feeding. Goats are not numerous; and asses and mules are seldom reared. A few Timor ponies have been imported; and the camel has been introduced, but hitherto has not thriven.

Birds.

Domestic fowls of every description thrive admirably, and may be reared at small expense. Geese become fat upon the native grasses; and the barn-door fowl picks up sufficient food in summer amongst the insects in the bush. Ducks likewise require very little artificial food; only they are subject to some unknown disease which checks their increase; while turkeys and pea-fowl, which are delicate to rear in Europe, require little or no care. Guinea-fowl also are easily reared; and all of them fatten better upon cracked maize than upon oats. The same holds true, also, in the feeding of horses. Besides the domestic fowls, game birds also are abundant, including the quail, snipe, land-rail, water-rail, duck, pigeon, and the native turkey, or bustard of the plains. Parrots are found in myriads, and at certain seasons make a tolerably good pie; and the cockatoo also is

Australia. New South Wales.

eaten. We may here mention that the tail of the kangaroo makes a richly-flavoured soup, which may be considered the only part of an indigenous quadruped fit for food.

Fishes.

Fish are plentiful in the bays along the coast, but they are not so abundant in the rivers. The fresh-water cod-fish, however, in the Murray River, are of a large size, weighing sometimes as much as 70 lb., and 30 lb. being common. Eels are also caught in the marshes and lagoons, 12 and even 20 lb. in weight. The salt-water fish are numerous. The schnapper is like our cod, and the best and largest fish in the Australian seas, with the exception of the trumpeter at Hobart Town. Rock-cod, flat-heads, taylor-fish, mackerel, soles, and guard-fish, constitute the ordinary kinds brought to Sydney market; but few of them have the substance and flavour of British fishes, from which they are distinct in species. Cray-fish are abundant, and fine flavoured; the crabs are of the most beautiful colours, but none of them edible. Prawns and shrimps are sold in the markets. Fresh-water mussels are found of a large size, but not wholesome to eat; and the salt-water mussels are small. Oysters, however, of three kinds are plentiful: the rock-oyster, the stream-oyster, and the mud-oyster, which are all edible; the stream-oyster being of the most delicate flavour. Turtle are found at Moreton Bay, where the aborigines are employed by the settlers in procuring them for the Sydney market; they are, however, not equal in flavour to the West India turtle.

Minerals.

Now that the mineral treasures of Australia have become the leading item in the wealth of the country, the attention of the government, and of the colonists generally, has been directed to the geological structure of the country. To give the most brief synopsis of this important subject would occupy more space than we can afford. A general view of the gold fields has been given in the section treating of the discovery: we must content ourselves here with noticing those other minerals which have been productive of wealth and utility to the colonists. Between the Blue Mountains and the sea-coast are those extensive sandstone plains where the strata are lying in a horizontal position with a slight dip to the westward. On this the city of Sydney is built, and the great mass of its buildings are constructed of this rock, which is more friable than ordinary freestone. The roads are "mettled" with the whinstone or basalt obtained from the Blue Mountain ranges. In the county of Argyle, a beautiful grained marble has been found, which makes up into handsome chimney-pieces. Copper has been worked for several years in the mountain ranges around Bathurst; but the ores that are the richest (pyrites) are found only in small quantities, while those most abundant are of inferior quality. Oxydulated iron ore, from which is manufactured the finest description of steel, has been worked at Berrima, but not successfully. Potters' clay and rock porcelain exist also among the rocks N. of Sydney harbour. But by far the most valuable mineral worked in New South Wales, prior to the gold discovery, has been coal. The coal measures on the Hunter River extend over the great basin of that river and its tributaries, down to the sea-coast at Newcastle, where the seam of coal is seen cropping out on the beach. Until within the last eight years, these coal measures were worked under a monopoly held by the Australian Agricultural Company. This, however, has been infringed upon successfully by the adjoining proprietors of land containing coal, who work now under sanction of the authorities. About 10 pits are in operation, and a considerable trade is carried on between Port Hunter and the adjoining colonies, as well as with New Zealand and California. For further particulars upon this subject, and an analysis of the soils as applied to agriculture, we refer the reader to the excellent work of Count Strzlecki.

An account of the aborigines of Australia will be found under the article AUSTRALASIA.

Australia. New South Wales. Population.

We shall now proceed to notice the increase of the European settlers in New South Wales. From our own experience, and the evidence of competent authorities, we know of no region on the globe where natural phenomena combine to render mere animal existence more desirable to the Anglo-Saxon constitution, or more propitious to the increase of the race.

It will be remembered that the colony, when first established at Sydney, as detailed in the first section of this article, consisted of 1030 individuals, 700 of whom were convicts; and that notwithstanding the famine and distress which occurred at intervals, and the discouragement of emigration by some of the authorities, the population, owing to the fineness of the climate and the number of convicts sent out, rapidly increased. A census taken at eight different times gives the following result in the month of March in each year:—

	Males.	Females.	Totals.
1810	...	...	8,923
1821	...	...	29,783
1828	...	...	36,598
1833	...	...	71,070
1836	55,539	21,557	77,096
1841	87,263	43,549	130,812
1846	114,709	74,813	189,522
1851	106,229	81,014	187,243

The apparent decrease at the last census was in consequence of the separation of Port Phillip, at which period it numbered an additional population of 77,000, giving a total of 264,000 for the old boundaries of the province before the gold discovery.

At the date when the following statistics were computed, transportation had virtually ceased for eleven years; hence it was not necessary to specify the number of convicts in a return of the population. Moreover, their influence on the social and political condition of the colony had become absorbed, and they were scarcely recognizable in the influx of free emigrants. Our information from the colony brings up the census to April 1853, exactly two years after the details given in the annexed table; and includes a fluctuating population attracted to her shores during nearly all that period by the gold discovery, and a re-emigration to Victoria upon the announcement of the superior gold-fields there. "The tide of emigration," however, as stated by his Excellency the Governor-general in his prorogation speech to the Legislative Council on the 28th December 1852, "is now steadily setting back to the colony." During 1852, 21,816 persons arrived in the colony, and 14,397 left it; 13,511 of whom went to Victoria and the other sister colonies, and of these 9886 returned; showing an excess of arrivals over departures of only 7419. The total population on the 31st December 1852, according to the government returns, was 197,168; 113,032 males, and 84,136 females; to which add the excess of arrivals over departures in 1852, and we have a total of 204,587 on the 31st December last. During this year, 1846 emigrants arrived at the public expense, and 756 at their own. The number of births registered during the year was 7675; of marriages, 1915; of deaths, 2600.

The proportion of the colonists from the United Kingdom and their descendants may be taken thus: out of 10 individuals there are 4 English, 3 Irish, 2 Scotch, and 1 other nations. Of course no apparent nationality of character has as yet resulted from this intermixture; but if we may judge from the few native-born men and women we have met, there is every likelihood of the future Australian people resembling their cousins of Anglo-Saxon descent on the other side of the Atlantic.

The following table exhibits a more particular classification of the inhabitants in the colony of New South Wales, within the restricted boundaries, according to the last general census taken on the 31st March 1851:—

New South Wales Census, 1851; *classified with reference to Sex and Age.*

Australia. New South Wales.

A visitor to the city of Sydney, if he mingles among the higher circles of its inhabitants, will find them surrounded by those elegancies, and possessing much of that refinement in their domestic relations with each other, which give the charms to civilized society. The governor-general and his official circle, of course, form the central sphere around which the lesser revolve; and these combine upon state occasions, when the hospitality of government-house is laid under contribution, to display a goodly assemblage of fashionable and elegant people. Altogether the stranger is pleasingly impressed with the facts that there is much wealth and liberality, and a tone of high intelligence, about the society of this fair city, and on the estates and homesteads of the settlers in the interior.

Government.

When the colony of New South Wales was first established, the whole powers of the government necessarily centred in the governor alone. In 1824, a council was appointed to aid and to control him in the exercise of his authority. Several alterations have since taken place, and the supreme authority is now vested, 1. in the governor; 2. in an executive council, which consists of the colonial secretary and treasurer, the commander of the forces, the auditor-general, and the attorney-general; and, 3. in a legislative council, consisting of the members of the executive council, with the addition of four other official and nine non-official crown nominees, and thirty-six elected members, making in all fifty-four members; who are presided over by a speaker elected from one of their number. The legislative power is vested in the governor and this legislative council; a majority of which must concur before any law can be passed, the speaker having a casting vote. Any member has the privilege of introducing a measure upon giving notice, as is customary in the House of Commons; the governor being represented by the colonial secretary, who brings forward all government bills. The recent act passed "for the better government of her Majesty's Australian colonies," after erecting the "district of Port Phillip" into the "colony of Victoria," enacts (§ 2), that the legislative council of New South Wales shall consist of such a number of members as the governor and council shall determine, of which one-third shall be appointed by Her Majesty, and two-thirds to be elected by the inhabitants. Electors are qualified to vote on possessing freehold estate of L.100 clear value, or occupying a dwelling-house for six months at an annual rent of L.10, or holding a depasturing license of the yearly value of L.10. The bills passed by the council must not be repugnant to the laws of England; and they do not become the laws of the land until they obtain the governor's assent; who has also the power of referring any measure before coming into operation, to obtain the sanction of Her Majesty, which entails great delay, if the act is obnoxious to the local government. For the sole administration of the laws there is a supreme court, over which preside a chief and two puisne judges. The supreme court is a court of oyer and terminer, and gaol delivery; it is also a court of equity, and a court of admiralty for the trial of criminal offences within certain limits: it is empowered to grant letters of administration, and it is an insolvent debtor's court. From the supreme court lies an appeal for all actions for less than L.500, to the governor or acting governor, who is directed to hold a court of appeals, from whose decision lies a final appeal to the queen in council. There are courts of general and quarter sessions, which have the same powers as those in England. Courts of requests have been established for summarily determining claims not exceeding L.30; and their decision is final. Juries now sit in civil and criminal cases. A very vigilant police has been established throughout New South Wales. There are benches of stipendiary as well as unpaid magistrates in Sydney and other principal towns, aided by head-constables and a civil and military police force at each station. The city of Sydney is incorporated, and divided into six wards, each ward electing four councillors. From these twenty-four councillors, six aldermen are chosen; and from the aldermen and councillors, the mayor is elected annually.

Australia. New South Wales.

Internal intercourse.

The country of New South Wales, recently a pathless forest, is now intersected in all directions by excellent roads, The royal mail proceeds from Sydney to all the different towns in the interior, and letters are delivered with punctuality and despatch. Postage stamps are used for letters as in Britain. Stage-coaches with four horses also start daily from Sydney, and from other places; so that there is every facility of internal intercourse by land; while numerous steam-vessels leave Sydney and ply along the coast to the different sea-ports. A railway also has been projected between Sydney and Goulburn; and there is every likelihood of the line being in operation in 1854.

Education.

Great efforts have been made in New South Wales to promote education among all classes, and numerous excellent seminaries have been established. Sydney College was instituted in 1830, where the youth of the colony are taught the ancient languages, English literature, and the rudiments of the sciences. On 11th October 1852, Sydney University was inaugurated by the governor-general. A classical professor, a professor of mathematics, and a professor of chemistry and the philosophy of physics, were appointed. The first session closed satisfactorily, with 24 matriculated students, in December 1852. It is founded upon the same liberal principle with regard to the exclusion of religious tests, as that recognized by the government in extending its support alike to all religious denominations. The number of schools in the colony on the 31st December 1852 was 423; number of scholars, 11,118 males, 10,002 females; total, 21,120. Of these schools, 227 were private, and 196 public ones. The city of Sydney possesses a mechanics' school of arts, a female school of industry, an infirmary and dispensary, a benevolent asylum, an Australian subscription library, a chamber of commerce, a museum and botanic gardens, a botanic and horticultural society, and various other societies connected with religion, literature, and science. The press, as usual, lends its aid to the diffusion of knowledge. In Sydney there are two daily and eight weekly newspapers, besides one three times, and two, including the *Government Gazette*, twice a-week: also one in Goulburn, two in Bathurst, two in Maitland, and one in Brisbane, published weekly.

Religion.

There is here, as in the mother country, a variety of religious sects, a statement of whose respective numbers will be found in the annexed classified population table.

It is here to be remarked, that all classes, of whatever creed, enjoy equal rights, and are equally eligible to offices of honour or emolument. One-seventh of the land was formerly appropriated to the support of the Episcopal Church: it is still applicable to the general purposes of religion and education, but without any distinction of sects, all of which participate equally in the government fund. The Episcopalian Church was formerly within the diocese of Calcutta; but is now subject to two bishops who reside in the country. There are, besides, 80 priests of this church, who have the charge of different districts in the country. There are six ministers of the Established Church of Scotland, and of the Roman Catholic clergy an archbishop, a bishop coadjutor, a suffragan bishop, vicar-general, and 38 clergy. The Wesleyan Methodists have 150 congregations, and about 10,000 attendants at public worship, with 24 ordained ministers and catechists. The clergymen of the synod of Australia in connection with the Established Church of Scotland are 16 in number. Those maintaining the principles of the Free Church of Scotland are 10. There are also 11 ministers belonging to the Presbyterian synod; five Congregational churches; one Baptist church; one German evangelical church, and a Sydney Bethel Union.

Finance.

The following is an abstract of the revenue of New South Wales in the years ending 31st December 1851 and 1852 respectively:—

Head of Revenue.	1851.	1852.
Customs	L.153,540	L.217,021
Licenses, postage, fines, fees, &c.	124,253	134,704
Revenue derived from gold	33,810	61,817
Territorial revenue	89,534	86,871
From the clergy and school estates	4,461	5,243
	L.405,598	L.505,656

The revenue of the customs chiefly arises from a duty on the importation of spirits, tobacco, wine, tea, and sundry other articles. The territorial revenue includes licenses and leases to occupy crown lands.

Commerce.

For the last twenty years, the trade of this important commercial colony has been forcing itself gradually upon the attention of our merchants and manufacturers. The rapid increase in the quantity and value of its exports, and the large proportionate consumption per head of British merchandise by its inhabitants, have ranked it among the first of our trading colonies. So great is the demand for manufactured goods, according to the latest advices, that the warehouses and stores are actually becoming empty, and the colonial traders are reaching an unheard-of anomalous condition in the history of commerce, namely, having an increasing market with wealthy customers, but lacking wares to sell to them. Even laying aside the value of the gold

Australia. New South Wales.

exported, the staple commodities of wool and tallow raised in the colony are sufficient to purchase for the colonists in a foreign market as much as L.8 per head of ordinary imports. The first of these articles demands some further notice. The imports of this valuable staple from the Australian colonies have increased so abundantly, that it has not only superseded entirely the importation of German and Spanish wools, but lately the French manufacturers have been large purchasers at the London sales of Australian wool, which they consider the best wool in the world for their fine fabrics. The origin and progress of this important branch of industry is remarkable. In 1810, only 167 lb. of wool were imported into Britain from Australia and Van Diemen's Land; a portion of which was sold for 10s. 4d. per lb. In 1815, 73,171 lb. were imported; in 1825, 323,995 lb.; in 1830, 1,967,309 lb.; in 1836, 3,564,532 lb.; and in 1852, it has reached in the aggregate from all our Australian colonies the enormous quantity, in round numbers, of 45,000,000 lb. Of this total weight, New South Wales contributed 15,268,473 lb. The colony was indebted for the introduction of merino sheep to the enterprizing spirit of Mr J. M'Arthur, in 1793. The flocks now in Australia, Van Diemen's Land, and New Zealand, number on their united pastoral lands, in 1853, upwards of 20,000,000 of sheep. The quantity of tallow produced is also important, and materially affects the quotations of Russian tallow in the British market. In 1850, the export of this article was valued at L.167,858, quantity 128,090 cwt., which decreased in 1851, for want of labourers, to 86,460 cwt., valued at L.114,168; and in 1852, notwithstanding the absorption of labour at the gold fields, the tallow exported was 84,464 cwt., valued at L.114,168. Gold, now forming the largest item on this export list, shows a continued increase, even by the month, at the rate of 50 per cent. From June 1, to December 31, 1851, the amount exported was, at colonial valuation, L.468,336; during 1852, it rapidly increased to L.2,744,961 for the year; and from January 1, to April 1, 1853, L.800,000. Hides also form a considerable article of export. The number shipped in 1851 was 68,641; in 1852, 73,104. Whale oil formerly composed a large staple export from New South Wales; but it has decreased latterly, and only a few whaling ships leave the port of Sydney. The bulk of the sperm oil exported is obtained from the American whalers which frequent Port Jackson to refit their ships. In fact, our more enterprizing neighbours in this peculiar pursuit seem to monopolize the whole trade in the southern seas, where it is estimated that they have upwards of 600 whaling ships afloat. New Zealand flax (*Phormium tenax*) also formed once a promising export from that country through New South Wales; but the Maori race have almost given up the labour of dressing it, and the little that is prepared is manufactured into ropes in the country. A small quantity of timber, consisting of cedar-planks, is also exported. Coals, as we have before remarked, form a large item in the intercolonial export trade with the colony; and grain, an import of considerable value. The total value of the imports in 1852, according to accounts laid before parliament, was L.1,563,931; of the exports, according to various official returns in the colony, including the amount of gold at 65s. per oz., L.4,604,034. In 1853, the total amount of exports was L.4,312,897, showing a considerable decrease, while the imports increased enormously, being not less than L.5,000,000. The shipping has increased along with the commerce. In 1850, the shipping inwards consisted of 421 vessels, of 126,185 tons, and outwards 506, of 176,762 tons; in 1851, 553, of 153,002 tons, carrying 7955 men, inwards, and 503, of 139,020 tons, with 7988 men, outwards; and in 1852, 673, of 183,002 tons, 9377 men inwards, and outwards 654 ships, of 139,020 tons, and 8130 men. Ship-building has not increased in proportion with the requirements of the colony. In 1841, 35 were built, of 2074 tons, and 110 vessels registered, of 11,250 tons; and in 1849, only 38 ships were built, equal to 1834 tons, and 126 were registered, equal to 8504 tons; the decrease being still greater in 1852.

Australia. New South Wales.

Prior to 1817 the currency consisted principally of the private notes of merchants, traders, shopkeepers, publicans; and the amount was sometimes as low as sixpence. In that year the Bank of New South Wales was established, with a capital of L.20,000, whose notes superseded this objectionable currency. Subsequently the capital was increased to L.300,000, and the bank exists in a flourishing state to this day. The same cannot be said, however, of the second bank, established by local shareholders in 1825, known as the Bank of Australia, with a capital of L.300,000 paid up; for after eighteen years' mismanagement, the directors had to prop up their bankrupt circulation by borrowing at a large interest from other banks, which ultimately not only swallowed up the assets of the company, but the unfortunate shareholders sustained further loss than their shares. In 1834, British capital and experience was brought to bear upon the commercial transactions of the colonists, by the establishment of the Bank of Australasia, with a paid-up capital of L.900,000, which obtained a charter of incorporation, and, with varied success, still exists. The most successful bank in Australia, is the Union Bank of Australia, an Anglo-Australian joint-stock bank, with unlimited liability, having a paid-up capital of L.820,000. From a report of the directors now before us, the amount of profit for the six months ending in the colony June 1852, was L.107,344, enabling them to pay a dividend, by way of interest, at the rate of 13 per cent. for the half year. The great profits shown by these results—unparalleled in legitimate banking—led to the formation of three new Anglo-Australian banks. These were the Joint-Stock Bank of Australia, the London and Australian Chartered Bank, and the English, Scottish, and Australian Chartered Bank. They began operations in Sydney during 1853; and at the close of that year showed a circulation in notes amounting respectively to L.71,400, L.15,200, and L.3300. The effect of this competition on the Australasian and Union Banks was to reduce their circulation in proportion. The aggregate amount of deposits in all the seven banks in December 1853 was L.5,065,700. Besides these joint-stock banks, there is a savings-bank under the control of the government, conducted on the same scale as British savings-banks. The private banks give no interest upon deposits. The following table shows the amounts of their respective circulation, total liabilities, coin assets, and capital paid up, in 1852.

Currency

Banks.	Notes in circulation.	Total Liabilities.	Coin and Bullion.	Total Assets.	Capital paid up.
New South Wales	L.311,174	L.1,602,119	L.565,216	L.1,996,280	L.300,000
Commercial	146,899	588,627	224,794	784,203	198,556
Australasia	182,074	651,623	297,297	599,052	900,000
Union of Australia	238,424	726,847	341,567	743,970	820,000
	L.878,571	L.3,569,216	L.1,428,874	L.4,123,505	L.2,218,526

Australia. The whole amount of British coin in the colony, at the end of the first quarter of 1853, was estimated in round numbers at L.2,000,000.

Victoria. II. VICTORIA has been a separate and distinct colonial government only since 1st July 1851. Prior to that date its territory comprised the southern portion of New South Wales, and hence sometimes officially designated the Southern District, in contradistinction to the Moreton Bay country, which was called the Northern District, the intervening territory being the Middle District. These names, which were imposed by the home government in 1842, are now superseded by later territorial changes, the last of which, in 1859, detaches the northern section as a new colony under the name of Queensland. The Port Phillip district, or briefly Port Phillip, was another of the early names for Victoria, and derived of course from the distinguishing feature of the harbour; besides which, as the late Sir Thomas Mitchell, while exploring the interior, had termed a portion of it Australia Felix, the ambitious colonists, improving the hint, had willingly extended so attractive a name to the whole territory. Some confusion that was likely to arise from these diversities was promptly arrested in 1851 by the gracious wish of her Majesty to distinguish the young colony by her own name.

Boundaries Victoria thus occupies the south-eastern extremity of the great territory of Australia. Its southern coasts are washed by Bass's Strait, into which its projecting headlands penetrate as far as 39. S. Lat. From Cape Howe, the eastern extremity, a straight line to the nearest source of the Murray separates Victoria from New South Wales, the river continuing the division till it passes 141. E. Long., which marks the South Australian frontier, to both the other colonies. Victoria is thus left with about 86,000 square miles, and is somewhat closely circumscribed between the spacious areas of the two sister settlements. The Murray, in its course along the north makes a great southerly deflection towards Port Phillip, which was probably not accurately known seventeen years ago, when the dividing line was fixed, but which leaves a large area on the north side territorially connected with New South Wales, but commercially and otherwise with Victoria. In the same way, Portland, the western seaport of Victoria, commands the commerce of adjacent parts of South Australia. The mining wealth of Victoria, by enabling that colony to construct railways and roads more rapidly than its neighbours, will presently still further disturb these boundaries. For the moment, however, the success of South Australia in the steam navigation of the Murray, and more lately also of the Darling, has been the most prominent circumstance in aiding a promising portion of the commerce of the interior, as well as appropriating it as the reward of that colony.

Discovery and name. This colony of Victoria is now from recent events so familiar to us, that we are apt to forget how brief an interval has elapsed since its territory, and even its coast-line, were totally unknown. At the beginning of this century Bass had only just ascertained that the southern coast of Australia was not continuous to Van Diemen's Land, but separated by the strait now bearing the discoverer's name. Bass, who made his important observations in 1798, by means of a whale boat from Sydney, reached only to Western Port. The discovery of Port Phillip, only about 25 miles farther west, was reserved for Lieutenant Murray, R.N., in February 1802, in the small government brig the Lady Nelson. In April following the celebrated Flinders came independently upon the same harbour, having also detected its not very distinguishable entrance. He noticed the strong eddying current caused at the entrance by the tides rapidly traversing a comparatively narrow channel with a very variable depth. This circumstance has caused the deposition of extensive sand-banks in the still water inside the Port Phillip Heads; and the process is so obvious and uniform that one is almost tempted to estimate the extent of the geological era that has elapsed since the ocean first broke into the great lake, and deposited the first of its daily tribute of sand. Flinders also observed the pastoral adaptation of the surrounding country, having landed between the present sites of Melbourne and Geelong, and walked across the grassy plain to Station Peak, where some observations were made. This country, then silent and empty, is now traversed by railways and electric telegraphs. The subsequent capture by the French, and long imprisonment at Mauritius of this distinguished navigator, prevented the results of his voyage from being given to the public until 1814. It is amusing now, when we consider the celebrity and importance of this well-known colony, and of its adjacent contemporary sister South Australia, to look back upon the time, little over a century, when these places were so utterly unknown that Swift selected this "north-west of Van Diemen's Land" for the scene of his Lilliputian extravagances.

Australia. Victoria.

Early colonization. The permanent colonization of the Port Phillip country dates only from 1835. The imperial government projected an earlier settlement by despatching, in 1803, a party of convicts under Collins, whose temporary location is still visible between the Port Phillip Heads and the hill called Arthur's Seat. The convicts were next year transferred to Hobart Town. The circumstance is interesting, from several of them who had run off having been left behind, one of whom, Buckley, the sole survivor, betook himself to aboriginal life, and met the colonists, above thirty years afterwards, as they arrived from Van Diemen's Land to retake possession. This was in the year 1835. Eleven years earlier, an overland expedition under Hume and Hovell had penetrated from New South Wales to the Port Phillip shore near Geelong; and during the previous year, in 1834, a pastoral and whaling settlement at Portland Bay had been effected from Launceston in the north of Van Diemen's Land, thus first occupying simultaneously at their respective extremities the two colonies of Victoria and South Australia.

Port Phillip. Portland failed to achieve much consequence. The great attraction was Port Phillip, so called from one of the New South Wales governors, Captain Phillip King. There were two parties of colonizing adventurers under their respective heads, Batman and Fawkner; the former having been first on the ground, the latter party having selected and settled upon the site of Melbourne. The former having procured an aboriginal conveyance of all the country hereabouts, came to repeated disputes with the later invaders, but were unable to evict the enemy. The claim was set up with but little of precedent for guidance, and good hopes of success were entertained by Batman and his friends; for, under the stimulating influence of some flour, blankets, tomahawks, &c., Jagga Jagga and other aboriginal worthies had very freely parted with their paternal acres, and that too with all the English formalities of signing their "mark," and delivering the handfuls of their lightly-held soil. In this case, as in the similar one subsequently of New Zealand, the government refused to recognise such contracts. Had it been otherwise, 600,000 acres would have thus passed into private possession, and including, as this area did, the towns and suburbs of Melbourne and Geelong, the property might, within twenty years, have been valued at many millions sterling. Batman's party was awarded a small remuneration of L.7000. Melbourne is already a large city, with extensive suburbs, representing an immense colonial trade, and containing 100,000 people; while Geelong contains one-fourth of that number. The early history of colonies is commonly barren of great public interest; but in this case the contrast is extreme, even in the uniform success of our colonial experience.

Australia. Victoria.

Mitchell's account of Australia Felix, and the great success and greater hopes of the earlier colonists of Port Phillip, fell contemporaneously upon the ears of the home public, and forthwith emigration to this country became a mania. The considerable capital that the emigrants took with them operated somewhat, as the gold discoveries did on a much greater scale a dozen years afterwards. Property "went up." In 1837 the chief towns of Melbourne, Geelong, and Portland had been laid out. In the two first there was already a busy scene of speculative buying and selling. All who aspired to fortune attended the land auction sales, government as well as private; and he who bade boldest generally came off best, as he was sure to resell at a profit. The end of this was a crisis in 1842–43, and a sore depression for a time, from which, however, the colony emerged, industrious and again prosperous.

Administration.

The Port Phillip shores having been first settled from Van Diemen's Land, the government of that colony put forward a claim to the administration of the new country. Its territory was comprised, however, within the ample area that had some time before been allotted to New South Wales, and the government and people of that colony were not slow in feeling alive to the awakening importance of the southern district. A magistrate was despatched from Sydney in 1836, and in the following year the governor himself, Sir Richard Bourke, visited the new scene. The settlement whose administration was thus coveted soon began to entertain ideas of its own independence. It was undergoing a very rapid development, so far as regarded the external aids of population and capital and the unrivalled pastures of the interior; while, from the seat of government being 600 miles distant, and the local subauthorities having very limited powers, public works and improvements, although urgently required, were very slowly and reluctantly granted, and by no means in proportion to the revenues contributed by the thriving young settlement. In December 1840 an assemblage of colonists, termed comparatively a great public meeting, passed with general consent resolutions approving of separation from the Sydney government. The subject was diligently followed up, and Dr Lang's motion in its favour, in 1844, in the New South Wales legislature, where he and several others represented Port Phillip, although greatly outvoted at the time, was the first of a series of steps that seven years afterwards resulted in the desired accomplishment.

Early statistics.

At this date of separation, when, on 1st July 1851, Victoria took its position as a distinct colonial government, only sixteen years had elapsed since Batman erected his hut upon Indented Head, to the south of the Geelong arm of Port Phillip, and not quite that interval since Fawkner's party squatted upon the grassy slope and open forest of gum trees that are now the busy market-square of Melbourne. The population, by the census of 2d March previous, was 77,345 colonists, and Melbourne contained 23,143; while the second town, Geelong, numbered above 8000. For that year the value of the imports was L.1,056,437, and of the exports L.1,422,909; the latter still consisting, as before, chiefly of wool (L.734,618), although for the last quarter of this year the Australian gold had begun to expand the colonial commerce, and amounted to L.438,777. The shipping entered inwards was 710, with a tonnage of 128,959. The public revenue was L.316,532. These were respectable attainments for so young a colony, and might even to-day have been much more copiously alluded to, were it not that all preceding colonial pretensions were utterly dwarfed by the expansion consequent upon the gold-mines.

Features peculiar to the country.

It is worth devoting a moment of attention, however, to the commerce that characterised Victoria, and indeed Australia generally, prior to the present absorbing and prominent gold-mining. We could only fully appreciate the lightly-timbered or open grassy country of Australia by observing the slow and toilsome process of removing a North American forest. Ere one, perhaps, of its innumerable giants had been cut down, the corresponding expanse of Australia was quietly occupied by sheep which browsed the natural grass, and each year yielded up the wealth of its valuable fleece without the cost of capital and almost without the effort of labour. Ere the whole forest was swept off, the Australian downs had perhaps already assumed a new phase. Well-made roads passed between fields of grain, and the smoke of towns and villages told of industry and prosperity to increasing numbers of colonists. The sheep had disappeared, driven off with ready step to remoter pastures, equally accessible and useful to them, although as yet shut to the slower march of agricultural and city industry. The wealth derived from the facile export of the wool had already contributed to social amelioration and progress, and the labour power that was not required for the extirpation of a colossal forest had been free for application in other ways that may have proved more congenial to comfort and wellbeing. These considerations explain the prompt and rapid development of Australian commerce, and the marked prosperity of its colonization. Victoria was a country ready made at nature's hand. The squatter or sheepholder at once used it, and as fast as he could breed or import his stock he spread them over its fifty-five millions of acres, of which two-thirds were available to him for pasture. In 1837 there were about 175,800 lb. of wool exported; in 1850 this quantity had increased to eighteen millions of pounds weight, with the additional export of 4500 tons of tallow. In the earlier years the young settlement was still importing sheep and cattle from the two senior colonies to the north and south; but four years had scarcely elapsed ere the fat stock of the Port Phillip pastures were already a promising article of export, and the subject of a trade whose increase and prosperity was interrupted only by that great event that has latterly made Australia the world's object, and introduced a marked change in this and many other of these colonies' earlier commercial and social developments.

Gold discovery.

We have now arrived at the great era of this colony, the discovery of its gold-fields. The accounts from California had early drawn attention to the probability of gold-mines being found in this part of Australia, and this idea was strengthened by the repeated assurances of Sir R. I. Murchison in England, and the observations and hints of Strzelecki and the Rev. Mr Clarke in the colonies. So early as 1849 there was a rumour of gold having been found at Clunes, and as this place has since proved a real gold-field, the report was probably true. At this stage, however, the question slept, until the colonists were startled into fresh life two years afterwards by the discoveries of Hargraves near Bathurst in New South Wales. These discoveries, which took place in February 1851, and were made public in May, caused a general and immediate search throughout all the quartz and gravel regions of Victoria, and the necessity of the case soon added the convenient word "prospecting" to the colonial vocabulary. Anderson's Creek, 16 miles east of Melbourne, discovered in August, was the first ascertained of the gold-fields; but although still worked, it has never attained to any celebrity. In September the great field of Ballarat, about 80 miles to the westward, was occupied, and its riches partially ascertained; while only a month later, and as the colonists flocked from all quarters to this attractive scene, the earlier diggers were already swarming off to the newer fields, for the time more attractive, around Mount Alexander. A few months more, and the yet greater marvels of Bendigo were proclaimed. For some time this field became the most conspicuous, and extraordinary quantities of gold were taken from it. By the middle of 1852 above 50,000 per-

Australia. Victoria.

sons were collected there, and the sudden demand for the necessaries of life raised the rate of carriage to 20s. per ton per mile, and advanced the price of flour from L.25, its rate at Melbourne, to L.200 per ton.

For several months during the spring of 1852 (August to November) the yield of gold in the colony was greater than it has ever since attained, and was estimated at 400,000 ounces, or L.1,600,000 per month. It was derived chiefly from Bendigo, and in particular from a district called the White Hills, which, however, were soon undermined and exhausted of their rich deposits, that were mainly contained in a very thin layer of the drift. In September the government had instituted an armed escort for the purpose of conveying, at a moderate charge, the gold to the shipping ports; and for a time these great results brought more than one rival escort company into the field, as the impatient diggers were provoked by the leisurely character of official procedure. Meanwhile, the news of these acquisitions had brought tens of thousands from the adjacent colonies, and towards the end of 1852 this stream was largely augmented by that which rolled in from the other hemisphere, from India, Europe, and America, but especially from the mother country. The population was doubled in twelve months, and the port at length so crowded with shipping that as much time and expense were involved in conveying the merchandize by lighters nine miles up the River Yarra to Melbourne as in the whole preceding voyage of half the world's circuit.

The natural effects of all this wealth and commerce soon appeared. At first, from the general desertion for the gold fields, landed and house property actually fell in value, especially the latter, as many tenements were left entirely empty, and were gladly let or sold at great reductions. This depression lasted but a brief interval. During 1852 and 1853 rents advanced tenfold, and many estates, town allotments, &c., yielded an annual rental of several times more than the fee-simple value just prior to the gold discovery. There were instances of fancy suburban sites being purchased for L.1 an acre, and re-sold for L.1000. But this upward rush in valuation could not go on for ever. It came to a halt towards the end of 1853, and then the lively colonists found that, like the oscillations of a pendulum, they had travelled beyond the right mark, and must be content partially to retrace. With little intermission, these inflated values have ever since been gradually subsiding; and, although they are still far in advance of the humble estimates prior to the gold-fields, yet they exhibit a very unsatisfactory appearance to the sanguine investors who went in for investment at the culminating season.

Population.

The progress of Victoria since 1851 is a series of marvels which no British colonial experience had ever previously exemplified. We have already given the results of the census of March 1851. A hurried and probably very imperfect census, taken in April 1854, gave the population as 236,000; but one more carefully completed in March 1857 made it 410,766, which number included 25,424 Chinese and 1768 aborigines. Exclusive of these races, there were 383,574 nearly all of European blood, but disproportionately consisting of 237,761 males and only 145,813 females. Of the Chinese only 23 were females. The aborigines were reduced to this slender enumeration from probably ten times the number at the first settlement of the colony twenty-two years previously. The distribution of the colonists in 1857 was as follows:—Melbourne and suburbs, 92,300; Geelong, 23,338; rural districts, 109,000; mining districts, 166,550. In the beginning of 1859 the population was estimated at 487,000. This number included about 30,000 Chinamen, a race whose presence in such large numbers in the colony has been the subject of much debate and difference of opinion, resulting, however, in the imposition of certain legislative restrictions having the object of checking the strength of the immigration. Australia.

Victoria. Commerce.

The imports for 1851, as we have seen, had attained the considerable amount of L.1,056,437; in 1857 they amounted to L.17,256.209. But these large figures scarcely exemplify the suddenness of the increase of the colonial commerce; for so early as 1853 the imports had attained to L.15,843,000, and the following year to no less than L.17,743,000; but the market having for a time been overdone by these efforts, subsequent years showed a diminution. The imports of 1857 were derived in these proportions:—From Britain, L.10,122,201; from British possessions, L.5,601,841; United States, L.784,643; other foreign places, L.747,524. The chief feature in these amounts is the large trade which they indicate with the United States, whence breadstuffs, furniture, mining-tools, &c., with increasing supplies of the great luxury of ice, are now regularly imported. The value of the importation from the States for 1851 was only L.122.

The exports in 1851 had amounted to L.1,422,909. In 1852 they are officially set down as L.7,451,509, but are known to have amounted to nearly L.15,000,000, as large quantities of that great yield of gold already alluded to had been ascertained to have left the colony unrecorded at the custom-house. In 1857 the exports amounted to L.15,079,512, of which L.10,987,591 represented gold, while the wool was L.1,335,642. The exports are nearly all shipped direct to Britain. The shipping inwards in 1851 numbered 710, of tonnage 128,959: while in 1857 it was 2190, of tonnage 694,564.

Estimate of gold produce of Victoria.

The yield of gold has fluctuated considerably in each year since 1851; but on an average, after due allowance for what has escaped official record, it amounts for the seven years ended in 1858 to about L.12,000,000 annually, and this large quantity is yet more remarkable as being about the same as that yielded by California. The fluctuations, under the rude mode of mining still pursued, are due materially to the regular supply or otherwise of rain for aiding the process of washing and supplying the numerous "puddling machines." The year 1854, which is lowest in gold production, was unusually dry; while 1856, which stands highest (next to the estimate for 1852), was remarkably of the opposite character. The following table will be interesting as furnishing three different views or estimates of the gold produce of Victoria. The first column gives the quantity brought down by the armed escorts, including, with those of the government, the temporary escort service in 1852–3 of two private companies; the second gives the quantity exported, according to the customs returns: the third exhibits the true yield of the mines for each year, as estimated by Mr Khull of Melbourne and others, and generally agreed to as correct, a due allowance having been made for the large quantities in the earlier years that escaped unrecorded at the seaports, and also overland into South Australia and New South Wales.

Gold Produce of Victoria, 1851–58.

Year.	From Mines by Escort.	Exported.	Estimate of Actual Produce.		
			Produce.	Value per oz.	Total Value.
	Oz.	Oz.	Oz.	s.	L.
1851 ...	104,154	145,137	345,137	60	1,035,411
1852 ...	2,039,382	1,988,526	4,247,657	70	14,866,799
1853 ...	1,874,409	2,497,793	3,090,342	75	11,588,782
1854 ...	1,476,666	2,144,699	2,192,699	80	8,770,796
1855 ...	2,132,398	2,751,535	2,964,073	80	11,856,292

1857 ...	2,481,020	2,762,460	2,606,040	80	10,424,160
1858 ...	2,371,269	2,555,263	2,421,461	80	9,685,844
Total..	15,105,266	17,831,404	21,400,936	...	82,362,192

Australia. Victoria.

If we estimate the whole at its proper value of 80s. per oz., instead of the lower rates that at first prevailed in the colony, there is still to be added L.3,241,551 to this large amount, making it L.85,603,743. This, then, will represent the total yielded by the Victoria mines up to the end of 1858. But in order to find the quantity exported (that being the usual mode of reckoning the gold and its effect upon the world), there must be deducted 216,501 oz., or L.866,004, as the quantity on hand in the colony on 31st December 1858, leaving the exact value of the quantity exported at L.84,737,739. The produce of New South Wales for the same interval, together with a small allowance for the other colonies, will add L.5,000,000 more to this last total. The New South Wales results can be arrived at only by the escort quantities, as the gold imported from Victoria, and afterwards re-exported, swelled the exports of the earlier years, and was thus reckoned twice over, while the operations of the local mint at Sydney subsequently diminished them. These details are given somewhat minutely, as they not only furnish a result of great interest, but correct many widely different estimates on the subject that have been made in this country and elsewhere.

Estimate of gold produce of New South Wales, &c.

Agriculture.

Agriculture, checked at first by the attractions and success of pastoral pursuits over the rich and extensive pastures of the young colony, was a second time depressed by the still more complete absorption of the gold-fields. Latterly, however, this state of things has been entirely altered, and during the present year (1859) Victoria has probably a greater breadth under cultivation than any of the adjacent colonies, not excepting even South Australia, where agriculture has been long and eminently successful. In 1851 there were but 57,298 acres cultivated. In 1857 these had increased to 179,082 acres; and in the following year to 237,729 acres, including 87,230 acres under wheat, 40,118 of oats, and 20,693 of potatoes, with a total value of crop of L.3,025,254.

Live stock and wool.

The effect of the gold discoveries has been to check, in a marked manner, that rapidity of increase in sheep-breeding and the production of fine wool that was previously the great feature of the colony. To a great extent this was the result of the sudden and large increase of the population, whose meat-consuming powers are beyond all the usual ratio of older countries and poorer masses of population. It was due partly also to the more precarious tenure of those large pastoral areas that were once occupied only by sheep and cattle, but now by tens of thousands of mining families. In 1853 the sheep numbered 6,033,367, which was the highest quantity attained. In 1858 they were reduced to 4,766,022, notwithstanding yearly accessions from the flocks of New South Wales. The other kinds of live stock have, however, steadily increased; cattle in the latter year numbering 614,537, and horses 55,683. The wool production has fallen off with the sheep. In 1854 the export had reached 22,998,000 lb., and in 1855, 22,353,000 lb.; while in 1857 it was only 17,176,920 lb., and in 1858, 20,645,334 lb., or an average of nearly 19,000,000 lb. These quantities of wool are beyond the proportion yielded by the corresponding number of sheep—a circumstance that arises from the fact, that a considerable part of the New South Wales clip is annually directed across the frontier of that colony for shipment at the nearer seaports of Victoria.

Other exports.

Tallow was another article which, following in the wake of the wool, gave promise of a large yearly trade, but which has been similarly depressed by the gold-fields' influences. The quantity exported for 1850 had risen to 4489 tons, but in 1855 it fell to 598 tons. There has since, however, been a considerable recovery, the quantity in 1857 having been 2632 tons, and in 1858, 1015 tons. Hides are now an export of increasing importance, as the facilities of inland communication induce nearly all to be despatched to market, where they arrive in better order than formerly. Sheep and cattle are still occasionally exported, chiefly to Tasmania, although this branch of business has much fallen off since the advance of prices caused by the gold. The black sand, or ore of tin, found in the remote gold district of the Ovens, adds a second metallic export, but it is as yet of comparatively small amount. Large masses of antimony are also met with in this vicinity; but the value of this article is insufficient to repay the cost of bringing it to market, and it awaits, therefore, like many other latent treasures, the future day of railway communication.

Australia. Victoria.

Upon nothing did the gold operate with more immediate and powerful effect than the public finances. The revenue for 1851 had been L.316,532, and towards the end of that year the legislature had sanctioned estimates for 1852, framed upon some like amount, with the addition of a modest and usual ratio of increase, which it was hoped the gold would at least not tend to diminish. But the revenue of 1852 proved to be L.1,577,181. That of 1853 was L.3,202,139, no less than a million and a half having resulted from the land sales. The land sales have since fallen off to a half or two-thirds of this amount, but the customs revenues and other items have steadily advanced; and the revenue of this young settlement, containing not half a million souls, has been maintained at about L.3,000,000 yearly. In 1857 it was L.3,175,888, and in 1858, L.3,039,791. These sums are exclusive of loans, with whose tempting facilities the colony is already getting familiar. After the first surprise of the government at the overflowing treasuries of 1852–53, the art of spending became so easy that during the following year the colony was already in debt. It is true that at this inflated time money went but a small way as compared with its former power, and the colony clamoured for public works and improvements to meet its expanding society and commerce. The legislature interposed a severe but effectual check on this extravagance, which was the more necessary, as a reactionary crisis had already set in which was diminishing the income, while the government were immensely increasing the expenditure. Prior to the era of self-government in 1856 there had been contracted a debt of about L.2,000,000, chiefly for the construction of water-works for Melbourne, costing altogether about L.800,000, and of aids for improvements of L.500,000 to Melbourne, and L.200,000 for Geelong. But subsequently to that period, a loan of L.8,000,000 was sanctioned for the construction of railways. Of this large amount, L.7,000,000 were to be raised in London, and already (1859) L.2,170,000 of the stock has reached that great monetary capital. The railway constructions proceed vigorously; and the debt is now rather over L.4,000,000. The revenues are derived chiefly from customs duties, which include an export duty of 2s. 6d. per ounce on gold, and from the sale of the public lands. For 1858 the former amounted to L.1,650,917, and the latter to L.699,846.

Revenues and public debt.

General progress.

The first inflations of the gold discoveries have passed away, and given place to steady industry and extensive and substantial progress. Melbourne, the colonial capital, as a creation of the last twenty-two years, is perhaps the most surprising object of its kind that has ever exhibited the marvels of human industry. The city and immediate suburbs, containing about 100,000 inhabitants, have an outward aspect of traffic and extent of commerce far beyond the usual proportions in other countries of even so considerable a place. Its streets and houses are lighted with gas, and both are plentifully supplied with fresh water. Three railways issue from its busy centre, besides long lines of good macadamized roads, one of which penetrates by way of Mount Alexander to the famous Bendigo, now the site of the large corporate town of Sandhurst. This road is above 100 miles in length, and is constructed for the most part at the enormous cost of from L.2000 to L.6000 per mile. There are

Australia. Victoria.

spacious theatres, hospitals, benevolent asylums, an university of the most ambitious dimensions, a public library (which, still unfinished, has already cost L.20,000, with L.7500 for the purchased portion of its library); and lastly, a Parliament-house, which takes position in the empire next to the magnificent palace of legislation erected at Westminster. Telegraphic communication is already complete throughout the south-eastern colonies, and across the intervening strait to Tasmania; and steamboats or other traders ply almost daily between the various seaports of the Australian group.

Crime.

The fame of her gold treasures brought a severe trial to Victoria's society. The adjacent penal settlement of Van Diemen's Land, for several years at first, resembled an open gaol, whence a resistless stream of the most depraved criminals spread themselves over the gold fields and highways, committing everywhere the boldest and most atrocious crimes. Intensity of feeling produced strong remedies, and the "Convicts Prevention Act," promptly passed by the legislature, alike required the Tasmanian immigrants to prove themselves non-convict, and also excluded those "conditionally-pardoned" offenders who were excluded from the mother country. The objection of the imperial government, that this measure interfered with the Prerogative, fell with decidedly light effect upon the angry Victorians, and did not prevent the act being renewed for those short periods that are permitted by the constitution, and that have more than once saved unseemly results between the imperial mother and her colonies, when there was less of mutual forbearance and consideration than is happily the case now. These evils have gradually ceased. The police became more efficient, and crime diminished, although the population rapidly increased. The number of convictions for felony was in 1851, 152; in 1852, 368; in 1853, 499; in 1854, 308; in 1855, 137; in 1856, 237; in 1857, 374. The year 1855, and the greater part of 1856, were times of commercial depression; a circumstance that suggests that these alternations of a generally thriving colony produce that marked diminution of crime that is usually the result of the opposite or prosperous seasons of our home country.

We shall conclude this part of our subject by a brief glance at the history, political and general, of the colony.

Victoria had formed the southern district of the colony of New South Wales until the year 1851, when it was erected into a separate colony under a lieutenant-governor, the governor-general for Australasia occupying the senior colony of the group, New South Wales, from which Victoria had been detached. The country, prior to this separation, bore, as already mentioned, the name also of the Port Phillip district, and sometimes Australia Felix. Only three counties had been at first marked off in the young settlement,—namely, Bourke, Grant, and Normanby. These respectively encircled the spots selected by the early colonists, and these spots have since become the chief seaport-towns of the colony, Melbourne being the capital of Bourke, Geelong of Grant, and Portland of Normanby. After the passing of an act of Parliament, and certain Orders in Council founded upon it in 1847, a further creation of twenty-one counties followed in the succeeding year. There are now therefore twenty-four counties, which have broken up the several large squatting districts into which the country had been previously distributed. Gipp's Land comprises seven counties,—viz., Howe, Combermere, Abinger, Bruce, Haddington, Douro, Bass; the central region has eight,—Mornington, Evelyn, Anglesea, Bourke, Grant, Talbot, Dalhousie, Rodney; the remaining nine are in the western district,—viz., Follett, Dundas, Normanby, Villiers, Heytesbury, Hampton, Ripon, Grenville, and Polewarth. The rest of the colony is comprised in three pastoral districts,—viz., the Wimmera, the Loddon, and the Murray.

Mr Latrobe, who had arrived in 1839, and had acted as "Superintendent" under the New South Wales government, was appointed the first lieutenant-governor, and remained till May 1854. Of a quiet and literary turn of mind, he was perplexed with the hurry and tumult after the gold discovery, and yet more by the disputes about the tenure of the squatters, or pastoral occupants of the waste lands, this powerful body having succeeded in obtaining from the imperial authorities certain long tenures and other privileges, well known as the "Orders in Council of 1847." Sir Charles Hotham arrived in the following month, June 1854, but died on 31st December of the year succeeding, in consequence, to some extent, of mental anxiety connected with the condition of the colony, social and financial, and the impending change to self-government. The financial troubles have been alluded to. Those of a social character were serious, although happily temporary, and culminated in the outbreak at Ballarat in December 1854. This unusual spectacle in British society had several causes. The rough and irritating task of levying monthly a direct personal tax of considerable amount was conjoined with a diminishing yield of gold to the miner; while a vexatious and suicidal parsimony of the government with the public lands, and a want of recognised political standing in the mining body, prevented that settled order and contentment which should rather have been a matter urgently promoted than otherwise towards the miners. A commission of inquiry, appointed by the governor, met the mining population in a cordial spirit; and the government having carried out the various recommendations, the gold-fields have since presented no exception to the common quiet and loyalty. Major-General M'Arthur, commander of the forces, assumed the acting governorship for twelve months, until the arrival of the present governor, Sir Henry Barkly, on 23d December 1856.

Australia. Victoria.

Government.

The acting governor inaugurated the first legislature of the free government. The colony had previously enjoyed the intermediate step in the customary progress,—namely, that of a legislature consisting of two-thirds representative, and one-third nominee, with a governor and executive responsible only to the crown. Now, however, the system was parliamentary. The colony and its old legislature, in drafting out in 1854 its new constitution, which was to receive the imperial sanction, had decided, in common with the other colonies in like circumstances, upon two houses of legislation. Both were elective, but the Council or Upper House was placed on the narrow foundation of a very high qualification: L.5000 of real estate, or L.500 a year for a member, and L.1000, or L.100 a year, for a voter, shows what princely ideas prevailed during these golden times of 1854. This body, consisting of thirty members, cannot be dissolved, but one-fifth of its number retires every two years. The assembly, sixty in number, is of three years' duration. Both bodies, in conjunction with the colonial public, have been latterly most active in shaping out the political future. The new constitution had been framed during times of hurry and gold excitement, and by a legislature composed partly of nominees, and otherwise meagre in its popular relations by the undue proportion of the squatting or crown-tenant element with which the old regime had instinctively fortified itself. It was therefore no sooner at work than it began to be attacked. The principle of the ballot had already been adopted by the old legislature; the new one added the manhood suffrage and the abolition of property qualification for the assembly, and increased that body to seventy-two members, with an electoral distribution based chiefly on population.

Religion.

The religious system is that of the perfect equality of all sects and citizens before the law, excepting as regards a state aid of L.50,000 annually secured by the Constitution Act, and distributable amongst the various Christian sects. This system has been abolished in South Australia, but continues in New South Wales and Victoria. It is, how-

Australia. Victoria.

ever, incessantly a bone of contention; now, by the limitation and inequality, as to civil rights, implied by the words "Christian sects" in the act; and again, by the anti-state aid views of certain sects, and perhaps of colonial opinion generally, when drawn out by repeated discussion. By a considerable majority, the new Assembly condemned the system; but a small majority of two in the Council still maintains the contention for a farther season. The census of 1857 gave the religious condition as follows, in a total population of 410,766:—Church of England 175,418, including 15,520 subscribing as "Protestants," and 221 as "Free Church;" Presbyterians, 65,935; Wesleyan Methodists, 20,395; other Protestants, 27,521, including 10,858 Independents, 6484 Baptists, 6574 Lutherans, 1480 Unitarians; Roman Catholics, 77,351; Jews, 2208; Mahommedans and pagans, 27,254; residue, 6774.

Education.

The state assistance continues to be bestowed on the two rival systems, the denominational and the national, of which the former, the longer established of the two, is by far the most prevalent. In 1857 the denominational schools numbered 399, the pupils 24,973; while the national schools were 101, and pupils 6113. The considerable grant of L.125,000 for that year was distributed in these proportions. The private schools numbered 138, with 3437 pupils. There are thus 638 schools, or 1 in 600 of the population; while the 34,523 scholars are 1 in each 11. The number of persons who could read and write in 1857 was 249,386, or upwards of 60 per cent. By a provision of the Constitution Act no person who, attaining to twenty-one years after November of this year, and being unable to read and write, is entitled to the franchise.

Present political condition.

Victoria, in common with the sister colonies, may still be regarded as in the act of re-adjusting the social and political state consequent upon the late introduction of self-government. They are, as it were, descending from the stilts of the old regime, and great interest must naturally attach to the question of the position into which, collectively or separately, they at length subside. Although it would be premature to pronounce positively and completely on this subject, yet something may be said of those features already assumed, which, as being to all appearance common to the Australian colonial picture, may the more certainly be regarded as normal and permanent. The tendencies are decidedly, we might say irresistibly, to those democratic equalities that in older countries are checked by the actually existing and old hereditary form of an opposite social fabric. The fact that every one has emigrated to better his condition by some kind of labour has a levelling influence upon class prestige, and this effect is strengthened by the independent position, and, in general, the ample wages of the labouring classes. In short, equality is alike the public opinion and the actual fact.

Prominence of Victorian example.

The surpassing importance of Victoria, which contains about half the total colonial population of these settlements, and whose capital seaport of Melbourne represents more commerce than all the others put together, has naturally given to it the lead in the political movement. So early as 1855 a principle tantamount to general or manhood suffrage was introduced successfully in this colony with reference to the peculiar case of the mining population, and was soon afterwards extended to the entire territory. South Australia and New South Wales have since followed this step. In the question of religion, the tendencies are unmistakeably towards entire separation from the state, which, administered as it may be by an executive of all variety of persuasions, cannot in any individual or sectarian sense be religious. The present state aid to religion, representing the only state tie, was introduced prior to representative government in these colonies. It has been already abolished in South Australia, and it seems to survive in the other colonies only by means of some protracted electoral inequalities of the past regime. The question with the colonists becomes one of civil rights, and the public feeling decidedly tends towards a perfect liberty and equality, religious as well as civil. In these circumstances, colonial orders of nobility, or colonial religious establishments, giving to particular classes or sects any status or privileges beyond what the rest of society enjoys, would probably be found, as far as may now be judged, not only an unpopular but an impossible intervention.

Australia. Victoria.

Comparisons, social and political.

These colonies have grasped the reins of their own self-government with an ardour that is truly the most gratifying response they could make to that imperial confidence which entrusted them with so grave a responsibility. Their Parliaments, unpaid as they still are in these countries of "working-men," sit for most of the day, and very often also for most of the night, over the public interests. The first assembly of Victoria's free government sat, with very slight exceptions, throughout a whole year; and the writer recalls the circumstance, that one of the debates, upon the important subject of the public land regulations, continued uninterruptedly for twenty hours, having commenced at noon and lasted till eight next morning. Earnest and energetic business has thus succeeded to the semi-amateur legislation of the past. The ranks of government are open to the ambition of persons from every class, and political and even social position are much less exclusively the result of polished education or accredited connections than of personal merits or usefulness. With this practical energy and adaptation to its own case the colonial picture wants the refinement characteristic of an old society. There is a constant fracturing of the upper crust in order to elevate to its envied stage successive masses of the competing crowd beneath. The curious in social questions may speculate on the alternative of the high polish that fringes the mass destitution of home society, and the ruder surface that covers the substantial wellbeing of colonial life.

Lessons from the past

Important lessons have resulted from past colonial experiences. A few years ago it was thought dangerous to give colonists much liberty. They were democratic, rebellious, and wickedly disposed to break off from home ties on every opportunity. These notions have proved quite unfounded. Self-government has promptly developed, indeed, those extreme popular ideas that may be regarded as representing the normal state of new and detached societies of our countrymen; but it has also strikingly increased their loyalty to the empire. Indeed, there can now be no doubt that the restrictions heretofore imposed on colonial liberty by imperial distrust were the sole cause of whatever savoured of disloyalty or discontent in the past. Perpetual interference with local concernments stirred up in the colonists everlasting antagonism to their governments, local and imperial. There is now in all this a manifest change. The colonists' differences are reserved for their own political parties, and the imperial authorities, by abandoning direct interference, have acquired a most powerful indirect influence that must ever be for good to the lively but inexperienced offshoot.

Our country may not henceforth be engaged in founding many more colonies. The earth is, after all, but a limited sphere, since we sport so nimbly over it by steam and rail; and there is no inexhaustible supply of empty areas to be still taken up in temperate and attractive climes. Were it otherwise, our thoughts might be profitably directed, and in no scant measure, to certain alterations in the old and established procedure for the nurture of British colonies. But even now, as the subject is still interesting, a brief allusion will be excused.

Against convict colonies.

In the first place, we must hope that there are to be no more bright visions of colonies founded by convicts; just as though vice were some imaginary attribute that made no difference to society, or might be balanced off by some

Australia. Victoria.

amount of money or other material consideration. Speaking as colonists, our imperial mother has for many long years been relieving, at our moral cost, the difficulties of her superabundant crime. But speaking also from the home view, has not this facility of transportation operated with fatally lax effects upon all preventive efforts, and brought annually unimpaired numbers to replenish the criminal field? It is fortunate for humanity that Britain is the only one among the teeming populations of civilized countries that has succumbed to the difficulty and responsibility of regulating within itself its own criminal elements. But at length the transportation system, under a stricter view of our duties, is likely to be abandoned, and for that purpose awaits only some adequate attainment in the neglected studies of preventive remedies and criminal discipline. As the protracted experiment has been enormously costly, so the windfalls of British expenditure to the favoured penal colonies have maintained a vexatious confusion in the argument. Eastern Australia has successfully resisted; but simultaneously the isolated and slow settlement at the western extremity has allowed the material to outweigh the moral balance. Britain, after a brief trial, was not prepared for a sudden and complete change; and accordingly West Australia, which opportunely offered, may be regarded as the medium by which our country is to graduate into the practice of its difficult but necessary duty.

Injurious political training.

So much for the moral training of colonies in certain striking instances; and next as to political training. The old proverbial discontents show that colonists are actuated by other than mere material wants. This should be the glory of our countrymen. But the grand error in past imperial management has been the ignoring or disliking of this circumstance, and permitting colonial liberties to be wrested, step by step, from the reluctant and resisting authorities. But in truth no private right should have been more sure to each colonist than this public right to the collective body, so soon as it was willing to undertake the responsibilities, and in a position to meet the expenses of its own government. The irresponsible administrations that were placed over young colonies had ever before them a vista of interminable warfare. The enemy was the colonial public, less some proportion, more or less considerable, of such upper-class life as might have arrived in the emigrating tide, and naturally attached itself by tastes and sympathies, and the hope of appointments, to a colonial court. The vicegregal circle might be small, but it had not the less an effective influence in its own locality, as the depositary of all power and patronage, and as standing indisputably at the head of fashion and society. If not always exclusive as to persons, it was inexorable as to principles; and so the Cavalier court and the Roundhead public stood irreconcilably at bay. The governor was a temporary personage of five or seven years' reign, but Government-House was a perennial corporation, true to the last for its anti-popular sentiments, and its revenue emoluments sweet because not beholden to popular sanction, and fighting to the end for its social and political supremacy against the vexatious progress of its vulgar foe.

Here we have a scene of permanent mischief-making, most of which might have been avoided by a simple understanding at the outset between the authorities and people as to the political future. The effects are injuriously lasting. The imperial government is slow to yield; but long after a decision in that quarter has been arrived at to grant steps of freedom to the colonies, the local authorities still strive, and not unsuccessfully, to defeat the imperial intent. New South Wales and Victoria, at first comprising one colony, are a case well to the point. When elective legislatures were given to Australia in 1843, imperial precaution required that one-third of the body should be of crown nomination. But to the colonial authorities this seemed a most inadequate protection against the common foe. The electoral arrangements were in their hands, and the squatters were the convenient medium of the occasion. Accordingly, the new Assembly emerged with a majority consisting of crown nominees and crown tenants,—a state of things that can hardly be said to have ceased until the recent advent of self-government. Hence a long anti-popular dominancy, with official powers and invidious class privileges and expectations that should never have been even thought of, and squatting antipathies on the part of the colonists which now threaten their sure re-action. When the people at last find themselves in power, most of the conspicuous colonists, and of those accustomed to public affairs, are those who have been arrayed against them. The altered circumstances do indeed open a door of escape that is not very vigilantly scanned in the general jubilee. Yet human nature is reluctant to stoop. To such causes must we in a great degree attribute the fact, that many colonists, of an education and position best suited to public affairs, do not come forward under the new condition, while many more, dwarfed and discontented, quit the colony. There are exceptions enough to show that the colonists can appreciate the higher attainments, and are not too categorical upon the exploded past.

Australia. Victoria.

Successful examples.

The examples of Victoria, South Australia, and New Zealand may teach us that the most prosperous colonies may be established without costing one farthing to the mother country. We can suppose there is no call now for establishing others. The later colonizing experiments in New Zealand are the successful solution of a long-vexed problem. The solution, too, is eminently pleasing, notwithstanding that any ideas of permanent dominancy either of Presbyterianism at Otago or of Anglican Episcopacy at Canterbury, are as futile as, in a liberal view of civil fraternity, they are undesirable. The ironical complaints of the New Zealand colonists, that the grass overspreads the untrodden approaches to the courts of justice, is only the natural result of a young colony favoured by a climate and country that alike stimulate and reward industry. Australia, on a larger and more noticeable scale, should have powerfully supplemented this happy picture, only for the social misfortune of its early convictism. Possibly we are not yet at the end of such inspiring instances of colonization, and the fact of the recent great clearance of official cobwebs with regard to colonies will not a little aid the emigrating enterprise of our day. Although the field of choice is contracted, yet the dangers and expenses are surprisingly diminished by facilities of navigation and the enlivening ubiquity of our race. The omnivorous wants of modern commerce will find in most new countries something having a value for exportation. Who can complain of the exile of colonial life when a few weeks now convey us to or from the antipodes? Colonizing expeditions, open to all classes, and headed by their future rulers and magistrates, are among the probable things of the present time, and broad and unclaimed acres are not wanting for their purpose. When such occasions offer, our home government, more discriminative than in past times, may better judge how to commit frankly to a young and remote society the administration of its own affairs, and may feel, too, that a fresh imperial domain thus acquired is the preferable alternative to an unclaimed waste, abandoned to nature or occupied by a handful of cannibals.

Under such reflections, we may regret the oversight that left the beautiful island of New Caledonia, with its unrivalled climate and capabilities, to pass, so lately as the year 1853, into the unfruitful hands of French colonization. If there were no other loss or inconvenience, the fact that this circumstance has resulted in the urgent demand for a powerful naval station at Australia, will illustrate how a momentous contingency may grow out of apparently very

Australia. Victoria.

slender premises. It is a commercial and common-sense axiom, to have a real purpose in view for every labour and outlay. But when rival wooden walls and bristling guns are accumulated at the antipodes, all perhaps under the cross grains of mutual misapprehension, it is allowable to hope that the whole may eventually prove a total waste of means, and that those waters that roll between the two colonial nationalities are still to be regarded as in every sense a Pacific Ocean.

Tropical colonies peculiar.

As experience makes us familiar with the diversified features of our colonial empire, two great classes of colonies will rise distinctively before us,—those of tropical and those of temperate latitudes. We may perceive already, in the instances of East and West India, as compared with Canada, the Cape, and Australia, that these two classes of settlements are respectively on a different path, and that a widely different destiny lies before each. We have hitherto alluded only to the latter class of colonies—to those that reproduce a British society; and nothing can be said here regarding the other class.

With respect to tropical Australia, it may just be remarked that, distinct as it is in its social destinies from the self-governed states of its more temperate latitudes, it should be distinct also in its political relations, and be retained as a crown colony, subject to imperial administration.

South Australia.

III. South Australia. When Captain Sturt discovered and explored the Murray River in 1830, and traced its course down to its embouchure into Lake Alexandrina,—now called Victoria,—he was of opinion that to the westward of that river, towards Gulf St Vincent, a rich and fertile land existed; and that probably the lake disembogued into the gulf. His men at the time had suffered so much from fatigue and privation, that it would have endangered the safety of the party if he had attempted to prosecute his researches further than ascertaining generally the extent of the lake. On his return to Sydney, however, he represented the matter so strongly to Governor Darling, that he sent instructions to Captain Barker, Commandant at King George's Sound—who was under orders for New South Wales—to land at Cape Jervis and explore the eastern shore of the gulf, and ascertain the outlet of the lake. Unfortunately that gallant officer, just as he had completed his task, was inhumanly murdered by the aborigines at Encounter Bay, while in the performance of a perilous portion of his duty. Mr John Kent of the commissariat department, who accompanied Captain Barker during the expedition, has recorded the particulars of this first exploration of the Adelaide country. The party, consisting of seven persons, landed on the eastern shore of the gulf, and proceeded inland in a north-easterly direction, ascending a range of mountains, of which Mount Lofty formed the highest peak; from whence they could overlook the gulf to the westward as far as York Peninsula. To the northward this range trended in an unbroken line, which settled the point that the lake had not an outlet in that direction: they descended accordingly and traversed the country through some fertile valleys and rich lands on Sturt's Creek, until they reached Encounter Bay, where the lake disembogued itself into the sea through an insignificant channel between hummocks of sand. Here Captain Barker gallantly stripped and swam across the channel, with a compass to ascertain its position. Mr Kent, in his MS. narrative, describes the circumstance in these words: "Curiosity prompted me to time his crossing. The current was running out strong; but he accomplished the feat, at 9·58 A.M., in 3 minutes. On arriving at the opposite shore, he ascended the sandhill, gazed around for a few moments, and disappeared." He was never seen afterwards. It was, however, subsequently ascertained that three aborigines had speared him, as he rushed into the water to escape from them: his body was carried away by the tide. Mr Kent on his arrival in Sydney gave a favourable report to Captain Sturt of the country explored, coinciding with that gentleman's own impressions. This partial exploration was described by Captain Sturt in his account of his discovery of the Murray River, in which he pointed this out as a desirable locality for the establishment of a new colony. Here accordingly the colonization commissioners of South Australia fixed the site of the future province; and forthwith despatched a surveying staff, followed by crowds of emigrants and a governor, before anything further was known of the capabilities of the country. The territory claimed by the ambitious and fallacious colonizers of this province was not less than 300,000 square miles—about 3½ times the size of Victoria; but notwithstanding the subsequent explorations of Captain Sturt to the N. and E. of the Gulf St Vincent, and Mr Eyre to the westward of Spencer's Gulf, the country traversed by Captain Barker and Mr Kent, including what they saw from the Mount Lofty range, comprises nearly all the arable or pasture land occupied by the settlers at the present day—an area not exceeding, at the most, 10,000 square miles of ordinary pasture-land.

Australia. South Australia.

Geography. Plate CI.

The boundaries of South Australia, according to the statutes of 4th and 5th Will. IV., cap. 95, are fixed between 132° and 141° E. Long., for the eastern and western boundaries; the parallel of 26° S. Lat. for the northern limit; and the southern boundary defined by the sea-coast, including Kangaroo Island. As already observed, this extensive tract of country measures nearly 300,000 square miles, or about 192,000,000 acres; the greater portion explored having been ascertained to be a barren waste, diverging into the stony desert of central Australia. The portion of this immense territory actually occupied by the colonists may be described as all that tract of land situated between Lake Victoria, ascending the Murray River as far as the "Elbow" in 34° S., on the E., and the eastern shore of Gulf St Vincent to the westward. The attempts to form small settlements at Spencer's Gulf and on Kangaroo Island have failed; and even York Peninsula possesses very little available country for the sheep-farmer or agriculturist.

History.

This colony was occupied as a British province on the 26th December 1836, by Captain Hindmarsh, R.N., who was appointed the first governor of South Australia. The powers with which he was delegated, and the constitution of his government were very different from those possessed by the early governors of the older colonies in Australia. With Mr Edward Gibbon Wakefield originated the new scheme of colonization. That gentleman wrote a series of pamphlets and letters to prove that colonization may be reduced to an art; of which he believed he had discovered the true principle. He held that, by placing a high value on the unreclaimed lands of a new country, and forwarding a labouring population out of the sale of those lands, the emigrants would of necessity work at *low wages*, as the purchase of the *dear lands* would be above their means; thereby securing to the capitalist investing in the land, a large interest for his money; and forming at once a community of labourers and artizans who would minister to the benefit of the landholders. But, besides these large landholders, a class of small farmers were to be induced to emigrate, by disposing of the land in small sections, to be cleared and cultivated by their families. The allotments of an embryo city, 9 square miles in extent, were to be thrown open at once to purchasers; so that the whole population should be concentrated around the emporium of trade. The principle contended for, therefore, was the opposite of what had been pursued in the pastoral colonies of Australia; for, while the latter consisted in the *dispersion* of the settlers, the new scheme was that of *centralization*. Which of them may be considered the most successful plan of colonization, the sequel will show. Meanwhile, by the industrious promulgation of these views before the British public, the press, and ultimately the government, looked favourably upon the

Australia. South Australia.

scheme. The result was the formation of a company called the "South Australian Colonization Association," and in 1835 they obtained a grant from government of the immense tract of land we have already described. The conditions were, that the land should not be sold at less than L.1 per acre; that the revenue arising from the sale of such lands should be appropriated to the emigration of able-bodied labourers to till the soil; that the control of the company's affairs should be vested in a body of commissioners approved of by the colonial office; and that the governor of the province should be nominated by the crown.

Hindmarsh, 1836.

Under these auspices, Governor Hindmarsh landed on the swampy shores of Holdfast Bay in December 1836, and with difficulty found his way to the contemplated site of the proposed city of Adelaide. The distance from the intended port being seven miles, he was at once impressed with the error of the commissioners' agents in fixing upon such an ineligible spot for a seaport town—a fault common, however, to new settlements in these distant colonies. His arguments upon this and other points with the local officers of the company, led to an unseemly discussion; so that after two years' administration of affairs he was recalled, and left the colony in 1838.

Meanwhile the emigrants, consisting mostly of "surveyors, architects, engineers, clerks, teachers, lawyers, and clergymen," with traders and adventurers of every description, were landed in thousands upon the mangrove swamps around the anchorage of the future Port Adelaide. After a very short time the majority of these settlers saw the nakedness of the land, and the absurdity of forming a colony without cultivating a foreign export. They thought it better, however, to keep silent, leaving the unscrupulous representations of the local agents to go forth, so as to induce others to come out, that they might dispose of their lands to better advantage. Then commenced a system of land-jobbing which can only find a parallel amongst the gambling transactions during the great railway-mania in England. The land-orders issued by the commissioners were negotiated like railway-scrip; and where the land had been actually surveyed, it passed nominally through, in some instances, as many as twenty purchasers, rising in value as it was conveyed from one party to another; payment being made generally by bills at long dates. In this manner town allotments which were originally set up to auction at L.2, 10s. per acre, soon reached the apparent value of L.2000 and L.3000; while country sections obtained at the upset price of L.1 per acre, realized as much as L.100 per acre. Those who had secured special surveys of 16,000 acres upon payment of L.4200 for that number of acres selected from the whole, sold allotments in imaginary townships at enormous prices. To this land-mania were added building speculations on an equally extravagant scale; and the wages of ordinary labourers increased to 15s. and L.1 per day. These facts, set forth in the most attractive light, were extensively circulated throughout England and Scotland, till the emigration fever rose to a pitch hitherto unprecedented; while the South Australian commissioners in London fanned the flame by publishing reports to raise the value of the land-orders issued by them. These, in several cases, were negotiated on 'Change at a premium of L.500 upon the order for 80 acres issued at the upset price of L.1 per acre.

Gawler, 1838.

Colonel Gawler was appointed to succeed Captain Hindmarsh, in 1838; and he arrived in the colony on the 13th October of that year. The apparent success of the land and building speculations deceived the new governor into a prodigality of expenditure during his administration, for which he has been unjustly condemned. It was, in fact, not more than equivalent to the apparent revenue of the country, but was found, however, at the close of three years, to exceed that income by L.400,000. Like the majority of the colonists, he imagined that all this interchange of *paper* gave *value to the land;* and as there was plenty of it belonging to the commissioners, there was little fear of the territorial revenue decreasing. As to ordinary revenue there was an increasing amount from the customs alone, which promised to meet all demands in time. But in 1839 the reaction took place, followed by a universal bankruptcy amongst the landholders, and the ruin of most of the small moneyed settlers. As the colony was established at its commencement upon an insecure foundation, it was no wonder that the inexperienced settlers, induced to build up the superstructure, should have failed in the attempt; for they were mostly townspeople who knew little or nothing about growing sufficient food for themselves. Hence their means were all expended on purchases from the neighbouring colonies. After three years' occupation of the country—while they had been buying and selling land by the thousand acres, and building towns and villages throughout the country—there were not 1800 acres of land under cultivation, and that mainly consisted of vegetable and flower gardens in the vicinity of their mushroom city. In 1840, when the writer of this article arrived in the town of Adelaide, there was a population of 8489 persons in the town, and only 6121 in the country, making a total of 14,610 for the colony in the fourth year of its existence. The exports for that year were L.15,650, or a fraction over L.1 per head; while the imports from Great Britain and the neighbouring colonies were above L.273,000, or at the rate of L.18, 10s. per head of population. While the revenue was not more than L.30,199, the expenditure amounted to L.169,966. This state of affairs was bolstered up as long as there was sufficient English capital brought by the emigrants to disburse private accounts, and money raised upon the governor's debentures to balance the public debts. But when the former ceased, and the latter were returned dishonoured, then the bubble burst. Great distress existed among the inhabitants of Adelaide at this time; food had risen to famine prices; and house accommodation was not to be obtained at any price. Consequently the incoming emigrants, unaccustomed to hard labour, suffered all the privation and disappointment which have so recently been renewed on a more gigantic scale in the neighbouring colony of Victoria. The writer of this article has paid 3s. 6d. for the 4 lb. loaf, and 1s. 3d. per lb. for meat; and he has seen 100 sovereigns paid for a ton of flour—the surplus stores of an emigrant ship. These facts are mentioned to show that there is nothing new in the high price of provisions quoted at Melbourne in 1852: it is merely the recurrence of a periodical state of affairs in the history of Australia. It will readily be supposed that much distress and privation occurred amongst these intelligent, well-educated, well-intentioned, but misguided colonists; the record of which should be a warning lesson to those amongst the middle classes who put faith in the schemes of colony-mongers.

Australia. South Australia.

The Anglo-Saxon race, however, are not easily crushed by disappointment; and it may be said with truth, that nowhere in the southern hemisphere has the energy of the race been better vindicated than here. The men rose up from their despondency ashamed of their unproductive hands, when they saw with what cheerful activity the weaker sex turned from the refinements of drawing-room life, to all the drudgeries of household work. Hundreds who had never put a spade in the ground before, left the town, and, on the fertile lands of the Mount Lofty range, and in the interior, cultivated the soil, and herded cattle and sheep. The result was that the colony not only became self-supporting but actually exported its grain, besides wool, tallow, and beef. Here were the true elements of colonial wealth and prosperity. It was by this labour, and these animals that *value was given to the land;* and it was at length found that the true principle of self-support was that of *dispersion* instead of *concentration.* The healthy progress of the colony for the next five years is honourable to the industry and perseverance of the

Australia. South Australia.

people of South Australia; and the flourishing condition of the colony in 1845, compared with 1840, as laid before a parliamentary committee in 1847 by Mr T. F. Elliott, is a bright spot in its history.

	1840.	1845.
Total population	14,610	22,390
In town	8,489	7,413
In the country	6,121	14,977
Number of public houses	107	85
Convictions of crime	47	22
Acres in cultivation	2,503	26,218
Exports of colonial produce	L.15,650	L.131,800
Revenue	30,199	32,099
Expenditure	169,966	36,182

Grey, 1841.

Meanwhile Governor Gawler was recalled in 1841, and succeeded by Captain Grey (now Sir George Grey, Governor-general of New Zealand), who had some previous knowledge of the colonial affairs from a residence in Western Australia, and who had visited the notorious model colony on the way home. By a course of strict retrenchment he reduced the expenditure in two years from L.104,471 to L.29,842. Added to this also was the discovery of copper in 1842, which increased the value of exports. The great yield of the Burra Burra copper mine did not occur, however, until after the above statistics were taken. This new article of export gave a fresh impetus to the trade and commerce of the port, which was by this time shifted a mile lower down the creek, while a good road was constructed between it and the capital. The history of copper-mining in Australia—as represented by the Burra Burra mines—like every other discovery and produce in this wonderful land, eclipses all that has been recorded of such workings in the Old World. It was not mining in the ordinary sense; it was quarrying. The leviathan mass of oxidated and carbonated copper ore lay on the surface in a kind of hollow where it was connected with a vein afterwards worked in the rock below. Success attended the efforts of the colonists in every direction as this new source of wealth distributed its benefits to all around. The fortunate discoverers and early shareholders realized fortunes; and one proprietor, who bought 100 shares at L.5 each, was in the receipt of L.11,000 per annum three years after it had been worked. Miners were brought direct from Cornwall; and every description of machinery was used to excavate the ore. Coal not being found in the colony, smelting operations were but slowly proceeded with. Many cargoes, however, were shipped to Sydney to undergo this process. Altogether the province of South Australia stood in as fair a position to rival its neighbour Port Phillip in the beginning of 1851, with the large export of its copper, and the probable yield of lead, silver, iron, and other valuable metals ascertained to exist in its mountain ranges at that date, as the most sanguine colonists could wish. That year, however, brought about a second period of depression in its short history which threatened to annihilate its commerce.

Discovery of copper, 1842.

Effects of the gold discovery.

The gold discovery, which was the precursor of unexampled prosperity to New South Wales and Victoria, proved deeply injurious to South Australia. The very fact of her population having become more a mining than an agricultural or a pastoral people militated against her. In twelve months after the discovery of gold in the Bathurst Mountains, it has been calculated that, out of a population of 70,000, 12,000 adults, and 4000 children, almost entirely of the male sex, left that colony. The city of Adelaide was left nearly destitute of able-bodied men, the mines were deserted, the stations abandoned, and almost every industrial occupation was at a stand still; while the government of the colony was for a time paralyzed. It was but for a time; for the legislative council—recently elected by the colonists—and the governor, Sir H. E. F. Young (Sir George Grey having gone to New Zealand), passed an act making ingots of gold, stamped by authority, a legal tender throughout the colony. This, added to the successful attempt of Mr Tolmer in forming a practicable route from Adelaide to Mount Alexander, brought a large portion of the gold from the colony of Victoria, and some from New South Wales, into the coffers of the South Australian merchants and the treasury. Those also who had left their families behind—which four-fifths had done—sent their earnings by this overland escort. These, to a certain extent, were expended in the country, while large quantities were purchased by the merchants, which drained the coin and bullion out of the banks. According to an estimate made by Mr Khull, bullion broker at Melbourne, the quantities of gold dust taken to Adelaide by land and sea from Victoria were as follows:—

Australia. South Australia.

"By overland escort, March to December 1852, 228,533 oz.; shipped from Melbourne, 17,331 oz.; taken by private hand, 178,160 oz.; estimated quantity taken in addition to above, 166,687 oz.; shipped from Adelaide to London, February to December 1852, 263,564 oz.

"Amount remaining in the banks, assay office, and private hand at Adelaide, 299,816 oz."

Valuing the gross amount at 76s. per oz., this would give a sum not less than L.2,215,167 added to the wealth of the colony; which, during the quarter ending on the 23d March 1853, has been the means no doubt mainly of swelling the exports to the enormous sum of L.954,760, a sum out of all proportion for the ordinary exports of that now insignificant colony when compared with its flourishing neighbour. With all their undoubted and praiseworthy energy, the South Australian colonists have not been successful in discovering a profitable gold field of any extent within their territory. The Echunga diggings, which promised much at first, have been almost abandoned. The following notice, which we extract from the *South Australian Register*, of the 7th February 1853, gives some idea of the latest yield of the Adelaide gold fields.

"Although there is at the diggings everything to indicate gold in large quantities, none have succeeded in realizing their hopes. The majority content themselves with what they can get on Chapman's hill and gully, knowing that, if a fresh place is discovered, they will stand as good a chance as those who have spent months in trying to find better ground. The quantity of gold taken to the assay-office having, during four consecutive weeks, amounted to less than 4000 oz., the governor has proclaimed that after the 17th of February 1853 the office will be closed."

With these favourable returns, a reaction has taken place in favour of the copper mines. Many who had been unsuccessful at the gold fields, or who preferred working for the baser metal, returned to the colony where they had more comfortable homes. The Kapunda, Burra, and other mines, which had ceased working for more than twelve months, were again put into operation; and the shares of the latter which had fallen from L.270 to L.60, were quoted in March 1853 at L.134½. Land likewise had risen in value. On the 1st June 1853, town lots were selling as fast as they were offered, at an average value of L.115 per acre; amounting to L.26,000 per month. The government had transmitted L.45,000 to the emigration commissioners in London, for the introduction of labour, although the colony had L.141,000 in the hands of that body for the same purpose. Agricultural operations were likewise progressing satisfactorily, and high prices obtained; while the ensuing harvest promised to be abundant. Until, however, this colony can raise from her own soil an equal amount to that which she now borrows, she cannot be classed along with the rich colonies of Australia. That no community in that land is more deserving of such a position is allowed on all hands. "Our neighbours of South Australia," says Mr Westgarth, in allusion to the delays, expense, and obstruction on every hand, which swell up an enormous account against the colony of Victoria, "have in these respects set us an example. Inferior in natural resources, they have surpassed us in energy of character, both of government and

Australia. South Australia.

people. The misfortunes of 1840 and 1841 with which they were bowed down had scarcely passed over ere they appear again erect and prosperous before us, as producers of the finest wheat on the London Corn Exchange; an expression equivalent, I may add, to that of the finest in the world. The gold fields of Victoria have again depressed them, but they are up and doing, as before, to make the best of what is left. Our highly auriferous soil is an accident, but the immediate projection of a road between Adelaide and Mount Alexander is a principle; and the first escort that traversed the new line, bringing with it L.21,000 worth of gold, gave alike the triumph and the renewal of such energy."[1]

Topography.

The settled lands of this partially explored colony were divided at an early date into nine counties, namely, Adelaide, Hindmarsh, Gawler, Light, Sturt, Eyre, Stanley, Flinders, Russell. In August 1851, two new counties were added—Robe and Grey. The territory is also divided into hundreds, each averaging about 100 square miles. The capital of the province is the "City of Adelaide," which is laid out upon nine square miles of land, of which about one-ninth is built upon and inclosed. Within the environs of this town are scattered a number of villages; including Klemzig, a village composed entirely of German immigrants. Twenty-five miles over the Mount Lofty range there is a larger hamlet of the same people called Hahndorf.

General aspect of the country.

If we speak of the general aspect of South Australia as contained within the limits of its available country, it comes under the general description of the Victoria territory and New South Wales; the greater proportion, however, being what is locally termed a "broken country" more allied to the east-coast ranges of the latter, than the extensive undulating open forest lands of the former. The Mount Lofty range, at the same time, is not more than ten or twelve miles distant from the eastern shore of Gulf St Vincent; whereas the ranges in New South Wales are seldom less than 80 miles distant from the coast. The shed of waters, likewise, which flows from the hills through the narrow flat where the town of Adelaide stands, consists of a few insignificant streams; and although they have mostly been denominated "rivers" by the company's surveyors, there is not one deserving more than the ordinary appellation of "creek." The only navigable stream amongst them is an inlet, through a mangrove swamp from the gulf. On the eastern shed of the Mount Lofty range lies the great lake Victoria, and its equally gigantic feeder the Murray, which we have described elsewhere. The two peninsulas which form Spencer's Gulf, are at the best indifferent forest land, with small particles of alluvial soil, the great mass being barren and worthless. The settlement at Port Lincoln has been abandoned on account of the poverty of the country.

The country between the eastern boundary of Lake Torrens and the Darling has been stated to be available for pasture land. We must be cautious, however, in accepting the reports of explorers despatched purposely to find good land in a barren country. The explorations of Captain Sturt to the northward, and Mr Eyre to the westward—on whose accuracy we can place implicit reliance—described the great mass of this territory as a region of desolation, where the hardiest indigenous plants and animals cannot find sustenance.

Soil.

On the alluvial slopes of the Mount Lofty range there is some of the finest agricultural land in Australia. The common average of wheat grown there is 45 bushels to the acre. So abundant was the yield in 1845, that after exporting about 195,000 bushels, chiefly to the Mauritius and England, the farmers had upwards of 150,000 bushels on hand over and above what was required for home consumption. And it is a fact significant of the progress of the colony, and the energy of the settlers, that, while in 1840 they were dependent almost solely upon foreign supplies of flour and grain, having only 2503 acres under cultivation, it increased in 1841 to 6722 acres; in 1842, to 19,790; and in 1843, to 28,690, of which nearly 23,000 acres were in wheat crop. In the year ending April 1850 there were 64,728½ acres under cultivation; of which 41,807 were in wheat crop; potatoes, 1780; gardens, 1370; vineyards, 282; and 13,000 acres in hay. In 1851 the land under crop was not less than 71,728 acres.

Australia. South Australia.

Climate.

The climate at Adelaide and its environs is about the same average temperature as Sydney; although the latter city is more than 1° in Lat. N. of it. From its situation, likewise, on a sand flat, very little elevated above the waters of the gulf, and its distance from the cool sea-breezes on the S. shore of Kangaroo Island, the atmosphere is in general more oppressive than the open country around Port Jackson. At the same time South Australia enjoys the salubrity of climate generally maintained throughout the temperate regions of Australia from Cape Leeuwin to Cape Howe; and it has also its share of the Austral simoom. According to the observations of Mr Wyatt, communicated to the government by the colonial surgeon, James George Nash, "the thermometer in summer averages 73° Fahr., and in winter 55° Fahr., shewing a mean temperature for the year of 65° Fahr.; being only 1° higher than the mean temperature of Madeira." "There is no endemic disease in South Australia. Bilious, remittent, and intermittent fevers are scarcely known. The prevalent fever is closely allied to the congestive fever of Bengal, and chiefly affects persons newly arrived. Eight-ninths of those cases that terminate fatally occur in persons who have not been one year in the colony. Organic disease of the liver is rare. Dysentery is one of the prevalent diseases, but yields readily to treatment."[2]

Diseases.

Vegetable and animal produce.

As already shown in treating of New South Wales under this head, the soil and climate is equally adapted for the growth of grain and of European fruits and vegetables. The indigenous grasses, however, which have made the pastoral productions of Australia equal to the most extensive in the world, are but limited. The live stock within the colony in 1851 was estimated at 1,350,000 sheep, 105,000 cattle, and about 7000 horses. Cattle thrive better on the pasture lands than sheep. Within the hundreds, pastoral leases are annual; without, they are of 14 years' duration; and the present leases comprize about 10,686 square miles. The revenue derived from occupation of land for pastoral purposes is only L.7984.

Animals.

The native birds are similar to those of the other south-eastern colonies; and poultry of every description thrive equally well. The fish in the gulf are also of a like kind; and the fresh-water cod found in the Murray River are so large and abundant, that at one time some enterprizing colonists preserved them for market. Like many other useful pursuits, this has been temporarily abandoned during the gold mania.

Minerals.

The mineral productions of this colony are numerous and varied; including jasper, chalcedony, and opal; iron, lead, and copper. The quantity of copper ore exported in the year ending 31st March 1852 was 7122 tons; and of smelted copper, 39,225 cwts.

Population.

In 1840 the population was 14,610; in 1845, 22,390; in 1850, 63,900, of whom 7000 were Germans. This latter element in the population of South Australia gives it a distinctive character from any of the other Australian colonies; and it is pleasing to see these industrious Saxon emigrants live so peaceably amongst their Anglo-Saxon brethren. "In the course of 1851 as many as 4221 emigrants were reported to have left the colony for the gold fields. This emigration subsequently increased to such an extent, that at one time the capital was said to be almost abandoned by its male population. Subsequent accounts, however, appear to show

[1] Mr Westgarth's *Report to the Melbourne Chamber of Commerce*, April 1, 1852.
[2] *Thirteenth General Report of the Colonial, Land, and Emigration Commissioners*, p. 141.

Australia. South Australia.

that the emigration is in great measure only temporary—that the bulk of the emigrants leave their families behind them, and after a short stay at the gold-fields return with the profits of their venture, which in many instances they invest in the purchase of land."[1] "At the end of 1851 the inhabitants, exclusive of a small detachment of military and the aborigines, are estimated at 66,538, and on the 31st March 1852 at 61,218."[2]

Government.

Before the promulgation of the recent act granting to all the Australian colonies a free constitutional government, the administration of affairs was vested in the governor, assisted by an executive council, composed of the colonial secretary, the advocate-general, the surveyor-general, and the assistant commissioner: to these were added four crown nominees. The elective principle has now been introduced into the legislature; and the governor-general of Australia is empowered to act as local governor within the province, when he visits it in person.

Religion and education.

In this colony, as in Victoria and New South Wales, there is no dominant church recognised by the state. From 1847 to 1851 an act existed empowering the governor to grant a sum out of the public funds in aid of religion (not less than L.50, nor more than L.150), to any religious body collecting an equal amount by voluntary contributions. The new legislative council, however, refused a renewal of this act, when it expired on the 31st March 1851. The number of churches and chapels, during the year ending at that date, which had received public bounty in aid of buildings and stipends, was 103, and the sum appropriated L.4431. The number of schools receiving aid on the same terms, a continuance of which was sanctioned by the new legislature, was in 1851, 132; the amount of aid being L.3310, and the number of scholars 4276.

Finance.

The revenue of the colony has increased in a satisfactory manner from the period of reaction in 1843, though unfortunately burdened with the debt incurred during Colonel Gawler's administration. This debt originally amounted to L.405,433 in 1841. In that year, however, Parliament struck off L.155,000 for necessary disbursements, and the treasury agreed to pay L.45,936; thereby reducing the debt to something more than L.200,000. This became a colonial bonded debt, represented by debentures guaranteed by the government. Governor Grey reduced this sum to L.85,800 in 1848, at the period of his departure for the governorship of New Zealand. From that date until October 1851, the present Lieutenant-governor Young has reduced it to L.10,300, having refrained from paying it off entirely on account of the depression of the Land Fund revenue. A comparison of the revenue and expenditure for the years 1840, 1845, and 1851, will show the revolution in the finances of this colony since it became a British province, independent of the company and the colonization commissioners. The latter body was dissolved shortly after its declared inability to meet the drafts from the colony, and the former association has recently become extinct.

	1840.	1845.	1851.
Revenue	L.30,199	L.32,099	L.169,469
Expenditure	169,966	36,182	143,981

The items for 1851 are exclusive of the territorial revenue, which amounted to L.107,201, and the expenditure to L.72,292. The amount expended under the head of public works in 1851 was L.18,228.

Commerce and currency.

The commerce and currency of South Australia have undergone various fluctuations. In 1841 the imports from Great Britain and the colonies amounted to about L.273,000, and the exports to L.53,500; in 1842 the former fell to L.163,000, and the latter to less than L.40,000. The latter gradually rose as the corn and copper swelled the import list, until 1849, when it amounted to L.485,951; and it fell slightly in 1850, on account of a decrease in the mines, to L.[illegible]. For the quarter ending 23d March 1853, the imports were L.440,328, and the exports L.954,760. The export of wool in 1849 was 2,243,086 lb.; in 1850, 2,841,131 lb.; and in the year ending 31st March 1852, 3,281,648 lb. The export of tallow was in 1849, 3867 cwt., and in 1850, 5271 cwt. The tonnage inwards and outwards at Port Adelaide for the year ending April 1849 was 112,338 tons; in 1850, 160,497 tons; in 1851, 166,950 tons. The currency, which was of a very objectionable kind issued by private traders at the commencement of the colony, was superseded by the establishment of the South Australian Bank, and a branch of the Bank of Australasia, and latterly a branch of the Union Bank of Australia. These banks gave great facilities to the mercantile portion of the community by negotiating their paper currency; which, at the time of the gold discovery, had reached an unusual amount. This event influencing the local trade, created a panic amongst the merchants; but with their usual judgment and foresight, they shipped off their surplus stock of merchandise to the gold colonies, receiving the dust in payment, which at once relieved them from their engagements. "The amount of current paper under discount in the three local banks before and after the panic is reckoned thus:—South Australian Bank before, L.280,000, after, L.120,000; Bank of Australasia, L.160,000, afterwards, L.60,000; Union Bank of Australia, L.120,000 to L.70,000; that is, L.560,000 reduced to L.250,000 in about three months, an improvement quite unprecedented, and which before its actual occurrence might have been deemed impossible."[3] Not the least important result of the gold discovery will be the effect of the intercolonial trade with Van Diemen's Land and South Australia in uniting more closely in social and political unity this whole group of colonies; especially New South Wales, Victoria, and South Australia. Hitherto the intercolonial traffic between their capitals was very limited, especially between Melbourne and Adelaide. Their origin having been contemporaneous, and their products similar, they had no variety of commodities to interchange, while their tariffs were formed on the old protection principle. Not only has the latter been modified to modern free-trade policy since the gold discovery, but the value of the gold transmitted by land and sea from Melbourne to Adelaide during the year ending 31st December 1852, amounted to L.2,215,167. The farm produce and bread stuffs alone shipped in return realized during that period L.250,000, or more than half the imports into Victoria under that head. Although a certain amount of jealousy still exists between New South Wales and her more fortunate younger sister, the traffic between the ports of Sydney and Melbourne has augmented in proportion with the prolific yield of the Victoria gold fields, thus materially cementing all interests. In allusion to this subject in a political point of view, we quote the liberal observations of Lieutenant-governor Young. "The year 1851 is memorable for the introduction of the elective principle of representation into the legislature, the free action of constitutional government, and for Her Majesty's gracious appointment of a governor-general of Australia, empowered to act as governor of each of its provinces when within the territory. This last-mentioned preliminary step towards a political confederation of the Australian colonies has proved very opportune and provident. The discoveries of rich deposits of gold, the more frequent intercourse thereby occasioned not only between Australia and

Australia. South Australia.

Great Britain, but also between the different settlements themselves both by sea and land, and the certainty that the steam navigation of the River Murray will now at last be effected, are circumstances which must accelerate, and were perhaps providentially designed to produce, that social union of the provinces on this continent, of which a common origin, allegiance, language, and legislation have formed the natural foundation, constantly strengthened and extended as it is by increased migrations from the parent state."[1]

Western Australia. Geography.

IV. WESTERN AUSTRALIA.—A line drawn due N. and S. upon the maps of Australia from the middle of the Great Bight on the S. coast to the head of Cambridge Gulf on the N. coast, along the meridian of 129° E. Long., forms the eastern boundary of this colony; the coast line to the westward forming its N., W., and S. boundaries. Its extreme S. is West Cape Howe, in 35. 10., and its extreme N., Cape Londonderry, in 13. 45., both headlands being in S. Lat. Thus, the greatest length of Western Australia is 1457 British miles, by an average width of 700 miles, giving an approximate area of 1,019,900 square miles. One-half may be considered within the influence of tropical meteorology, the other half within the temperate zone. This territory includes the earliest discovered portions of Australia. The proclamation of such extensive boundaries for this colony was apparently intended for the purpose of excluding any other power from forming a settlement on the coast; as there was ample room at the S.W. angle known as Leeuwin Land for any settlement likely to take root in the country. As it is, there are not more than 3000 square miles of land around the Swan River settlement, and only a few hundred square miles in the vicinity of Albany, King George's Sound, occupied by the settlers as agricultural or pastoral lands in 1853. When we take into consideration that this colony has been established so far back as 1829, we cannot but conclude that it must either be naturally ill-adapted for a British settlement, or that something radically wrong in its management must have retarded its progress so far behind its contemporaries on the E. coast. As will be shown afterwards, both of these influences have checked the advancement of Western Australia.

General History. Swan River.

In August 1829 Captain Stirling, who had previously explored the coast, arrived at the proposed site of the new settlement on the Swan River, to which he was appointed lieutenant-governor. He found that several ships had arrived from Britain in the previous months of June and July with numbers of anxious settlers; who, at the very outset, were discouraged by the appearance of the land on the banks of the Swan and Canning Rivers, besides encountering the inclemency of the weather (for it was winter in Australia) without any other shelter than the tents they had brought with them. By the end of the year there were 1290 persons in the colony including non-residents; and others were gradually flocking in without any previous preparation having been made for the accommodation of their wives and families. In fact so little care had been taken to plan out the proceedings of the government and the situation of the colony, that there was not an acre of ground surveyed until several months after the first arrivals. All that was known of the proposed settlement existed only on the map—where counties and towns were liberally scattered over the supposed surface of the land. This, coupled with the fact that the majority of the newly-arrived settlers were townspeople or small capitalists, unaccustomed to manual labour, and unfit under any circumstances to struggle with great difficulties, soon produced a state of general suffering and distress. The governor did all he could to alleviate the hardships and disappointments of the settlers; but his own circumstances were hardly better than those of the rest, both he and his officials having undertaken their duties on the stipulation of payment in land. Instead of a thousand or fifteen hundred pounds a-year, he was to obtain a grant of 100,000 acres of land, and his subordinates 20,000 acres, down to 2000 and 3000 acres in proportion. In like manner, if a settler brought wealth, in the shape of agricultural implements, live stock, or labourers, he was to receive an equivalent for the benefit he thereby bestowed on the colony, by a grant of land. If a builder erected government works, or a surveyor parcelled out the land, they were both to receive a portion of their remuneration in land. In fact so much had been left to this system of barter, that the government and the colonists had entirely overlooked the necessity of a sufficient metallic currency to negotiate ordinary transactions. Hence they were often unable to purchase the necessaries of life from the neighbouring colonies. Meantime, so utterly paralyzed were the authorities, that they even neglected to survey the land which they considered the pabulum of their existence. Persons settled down where and how they liked on the banks of the Swan and Canning Rivers. The land they had expected to be surveyed, and the towns they had expected to be built, were nowhere to be found. Upwards of fifty ships had arrived by March 1830, and nearly 2000 immigrants with property to the amount of L.100,000, while scarcely twenty houses had been erected for their accommodation. At last a township was marked out on the Swan River, called Perth, and some degree of order began to appear out of the chaos by the close of the year, as the governor took up his quarters at this future capital; not, however, before many of the most energetic emigrants had either left for the neighbouring colonies, or returned home to warn their fellow-countrymen from proceeding to this Utopian colony.

Australia. Western Australia.

The history of New South Wales recorded the sufferings and privations experienced by the pioneers of that colony, although they were selected from a proper class for the purpose. Much more, therefore, was it to be expected that such hardships should fall to the lot of the first settlers at Swan River, who were totally unfitted for the laborious enterprize of founding a colony. The *ladies* and *gentlemen* who formed the *pioneer corps* of settlers were landed upon the shores of a naturally sterile region without any greater preparation for the grave and difficult undertaking of founding a new British province, than if they had gone out upon a holiday excursion in the woods. There is no greater fallacy entertained by theoretical colonizers, than this romantic method of forming new colonies. Colonization is a work of the most profound and serious nature, and does not bear to be handled by quacks and empirics in political economy. It is a matter for the grave deliberation of the state, which ought to protect the people from the cruelty of those who receive their money for lands which have no value imparted to them by labour. The agrarian system of colonization attempted in this instance proved a total failure, and to this day not one tithe of the lands granted has ever been properly surveyed.

For twenty years after the disembarkation of the first colonists, the Swan River settlement has struggled through a feeble existence. Governor Stirling was succeeded by Governor Hutt, who tried manfully to restore confidence to the colonists, and induce new settlers to come out. He in turn was succeeded by Governor Fitzgerald, the present ruler. In vain have they attempted, with the assistance of the colonists, to raise the colony on a par with her sister provinces in South-eastern Australia and Van Diemen's Land. So late as the year 1848, things had reached such a state of general depression, that the inhabitants had taken it seriously into consideration whether it would not be advisable to abandon the settlement altogether. About this time there was a demonstration on the part of the neighbouring colonists—which we have noticed elsewhere—against the land-

[1] Despatch of his Excellency Lieutenant-governor Young. *Reports*, p. 228.

Australia. Western Australia.

ing of convicts on the eastern shores of Australia. It occurred to this remote community to petition for what their more successful neighbours refused. Consequently in 1849, exactly twenty years after the first settlement, a band of convicts arrived from the parent state, and at once gave new life and vigour to this languishing colony. A correspondent of the *Times* at Perth, writing in January 1853, says, "The advent of convicts, after three years' experience, has been found to contribute more to the well-doing of the pockets of the settlers than detriment to their morals." The most satisfactory results have been received of the progress of the colony under these circumstances to the 8th June 1853. The inhabitants at Perth had held public meetings expressing a desire for the importation of 1000 convicts annually. Up to that date 2000 had arrived; and a less severe system had been adopted towards them than that which had prevailed in Van Diemen's Land and New South Wales, and with the most beneficial results. If this class of labourers had been sent out to clear the wilderness, and construct roads, prior to the arrival of Governor Stirling, and the well-meaning non-labouring colonists who accompanied him, how different a position might Swan River now have held among the flourishing provinces of Australia!

King George's Sound.

The settlement at King George's Sound was formed much earlier than that at Swan River, in anticipation of a projected scheme of colonization by the French government. It was effected in 1826 by the government of New South Wales, who despatched a detachment of the 39th regiment under Major Lockyer for this purpose. After four years' occupation as a military post, the settlement was ordered by the home government in 1830 to be transferred to the government at Swan River, both being within the new colony of Western Australia. During the next twenty years of its existence it survived actual desertion, in consequence of its excellent harbour being frequented by whaling ships, which found abundance of whales off the coast. Since the establishment of steam communication between England and Australia, it has come into notice as the first coaling station for the steamers on their outward voyage, *via* the Cape, to South Australia, Victoria, and New South Wales; and there is every likelihood of the little township of Albany becoming a thriving seaport. "The Sound is a magnificent roadstead, with from 7 to 15 and 20 fathoms water, completely sheltered from S.W. to E., and partially by two islands to the S.E. It is only open to southerly winds, which in this locality bring fair weather. On the W. the Sound is separated by a long tongue of land, terminated at its northern extremity by Point Possession, from the Princess-Royal Harbour. The entrance to this nearly circular bay is between Point Possession and Mount Clarence; being not more than 200 yards across, with a depth of 4½ fathoms water. Princess-Royal Harbour is capable of containing many hundred vessels: it is the finest harbour known to exist in Australia to the W. of Spencer's Gulf. It enjoys an equable climate, the thermometer, during nineteen months' observations, ranging from 40° to 76° Fahr. Vegetables also grow luxuriantly."[1]

Topography.

At the outset of the colony there were fifteen counties laid out on the map, arranged in apparently compact sections of about forty miles square, along the coast from Cape Leschenault to Point Hood, namely, Twiss, Perth, Murray, Wellington, Nelson, Sussex, Lanark, York, Grantham, Wicklow, Goderich, Stirling, Hay, Plantagenet, Kent. Subsequently eleven were added to these along the territory to the N., which was named generally Australind; and from recent explorations promises to furnish good pasture land for sheep and cattle. These counties are, Melbourne, Glenelg, Grey, Carnarvon, Victoria, Durham, Lansdowne, Hawick, Beaufort, Minto, Peel. The principal places claiming the title of towns are Freemantle, Perth, and Guildford, on the Swan River; Kelmscott on the Canning, and Albany at Princess-Royal Harbour. Australia. Western Australia.

General view of the country.

The general aspect of the forest scenery, mountains, rivers, and coasts, is the same as on the E. coast, which has been already described; with this difference, that the mountains and rivers are upon a less extensive scale. In comparison, the former seldom attain half the height and extent of range; while we have no evidence as yet of any stream approaching to the Murray in its ramifications. Much however remains to be explored in this quarter. "The highest mountain known is Koikeunneruf near King George's Sound, which attains the altitude of 3500 feet. The principal range of hills extends in a northerly direction from the S. coast, near Cape Chatham, for at least 300 miles."[2] This range no doubt is continued more or less parallel with the N.W. coast, about the same distance inland, judging by analogy, as its greater counterpart on the eastern coast; the great Australian desert between forming a barrier to any internal communication from the one coast to the other.

Plants.

Although the botany of these two great meridian ranges, trending in a general course N. and S. from the middle of the S. temperate zone, to the middle of the Tropic of Capricorn, is generically the same, yet the majority of the plants are specifically different. Probably from the lesser heights of the mountain ranges failing to absorb the same amount of moisture as those in the higher altitudes of the Australian Alps, the vegetation of the temperate regions of Western Australia is of a more arid nature than that in the S.E. latitudes. Here succulent plants are not only rarer, but the native grasses are scantier; and the extent of pasture land within the known boundaries is of a very limited description. To give some idea of this limit, we shall quote the latest returns of live stock.

Pasture land.

	1850.	1851.	Increase.
Horses	2,635	2,978	343
Horned cattle	13,074	15,315	2,241
Sheep	128,111	141,413	13,302

Wool.

The value of the wool, which is considered the staple export of the colony, amounted in 1850 to L.15,482, and in 1851 to L.17,883. Governor Fitzgerald remarks upon this head, in a despatch dated Government House, Perth, April 12. 1852, "I fear that unless new grasses spring up, or are introduced into our pastures, we shall never be able to rival in this respect the production of the eastern colonies. Our lands fit for sheep are so small in extent in proportion to the rest of the colony, that a limit will soon be arrived at unless better pastures be discovered. Should such exist, they probably lie far to the N.E." This is conclusive, without even referring the reader to the statistics of the eastern colonies already given, to satisfy the most sceptical mind of the inferiority of its pasture lands compared with the verdant plains and valleys of Eastern Australia. There are single settlers in New South Wales who possess as much stock as the colony altogether; and this after a growth of 22 years. These facts will show that natural disadvantages have retarded the progress of the colony as well as original mismanagement; for although the colonists could raise enough of vegetable produce and animal food for their subsistence, they lacked a sufficiency of the pastoral exports of wool, tallow, and hides, to constitute them a successful producing community.

Agriculture.

This poverty of production is also apparent in the agricultural records of the colony. Up to 1851, the colonists were dependent upon shipments of agricultural produce from the eastern colonies. The number of acres in crop

[2] Well's *Australian Geography*. Sydney, 1848.

Australia. Western Australia.

that year was 7297¼, showing a decrease for the year of 121¾ acres. "This is attributable to many causes, the high price of labour, and the distressed state from which the colonists were only just emerging. Many of the agriculturists, however, have now freed themselves from their great difficulties, and there is every reason to hope that a very large breadth of wheat will be laid down this year."[1] There is no doubt that when the colonists obtain that cheap labour of which they are in want, much will be done to render them independent of foreign supplies of provisions. This, however, sufficiently testifies the poverty of the land, and corroborates the statement of disinterested parties, that the soil is not remarkable for that richness of loam and decayed vegetation which distinguishes the soils of Van Diemen's Land and South-eastern Australia, which yield averages of 40 and 45 bushels of wheat to the acre. At the same time there is abundance of land for all ordinary farm purposes around both settlements, on Swan River, and at King George's Sound, suitable for the growth of all esculent roots and fruits required by the colonists. There is no doubt also that the extreme dryness of the climate, and the devastating summer conflagrations throughout the forest lands, prevent that accumulation of mould from decayed vegetation which characterizes the virgin soils of all lands throughout the world. This arid climate, however, is even more conducive to the health of Europeans, than that of the eastern colonies. Endemic or epidemic diseases are unknown, and "the country maintains its character of being perhaps the most healthy on the globe; there having been only 37 deaths recorded during 1851, in a population of 7096 souls."[2] This average, however, is taken after the introduction of convicts in the previous year, which augmented the white population by nearly 1000 persons. In 1850 the population was 5293, which increased to 7096 in 1851. Of these 4523 were males, and only 2444 females, or nearly two of the male sex to one of the female. This disparity of the sexes has called forth a petition from the colonists to equalize the numbers, by requesting the government to forward females from the pauper institutions in England. The government have not acceded to this; but the Colonial Land and Emigration Commissioners report, "That under instructions from Sir John Pakington, they have endeavoured partially to remove this disparity, by sending out at the expense of the parliamentary vote, an additional number of women. Thus, since October (1852), we have despatched three vessels, carrying about 760 souls, of whom 26 were convict families, 36 were single men, while as many as 278 were single females; and the desire to emigrate to any part of Australia is now so strong, that we experience no difficulty in selecting for this colony very eligible females, without having recourse to the workhouses."[3]

Climate. Population. Female emigration.

Religion and education are less zealously nurtured in this small community, than in the eastern colonies. Governor Fitzgerald, in the able despatch we have already quoted, remarks, "I regret to state, that the schools at the Vasse and Murray have been discontinued for want of scholars; and it appears to me, that if a superior description of masters be not furnished for our colonial schools, education generally throughout the colony will be regarded as of so little importance, that great difficulties will hereafter arise against any endeavours that may be made to establish a regular system of superior instruction."

Religion and education.

The revenue for the financial year ending April 1851, amounted to L.25,167, being an increase over the year 1850 of L.6029, which was mainly attributed to the increase in the customs caused by a greater amount of duties paid on spirits and wine in bond. The expenditure for 1851 was L.23,926, being an excess of L.7252 over 1850. This is to be attributed chiefly to the exigencies of the service consequent on the introduction of the convict system; and to the high price of food, a result no doubt of the gold discovery in the east, rendering necessary an increase of the salary to the government officers. The colony is now free from all debt bearing interest, which it was found necessary to incur during the distressed period of its existence. The imports during the year 1850 were L.52,351, and in 1851, L.56,958, the latter giving an average of L.8 per head of population. The exports, during the same years, were respectively L.22,195, and L.26,870, or less than L.4 per head of population for 1851; showing a balance of trade against the colony of more than 100 per cent. This is not a very encouraging balance-sheet; but we presume the anticipation of a large government expenditure has been the cause. The shipping has doubled itself within two years. In 1849 7952 tons arrived in the ports, which had increased in 1851, in consequence of the arrival of the convict-ships, to a gross tonnage of 16,540. These figures give no very high idea of the commercial state of this colony; but the future is not without hope. No rich gold field has as yet been discovered, but copper and lead ore, and other metalliferous minerals, have been ascertained to exist in large quantities, indicating the proximity of valuable mines. The Geraldine lead mine is now in operation; and the company who work it have smelting works on the spot. It is satisfactory to find, that one of the most sanguine men in the community is the governor, whose despatch in 1851 ends as follows: "In conclusion, I have to remark, that such are the inducements to remain in the colony, from the government expenditure, the high rate of wages, and from the circumstance that most persons who have been any time resident in the colony have some interest therein, comparatively few persons as yet have left us either for Melbourne or Sydney; all classes appear prosperous and contented; and should the present system of the introduction of convicts continue, I have little doubt but this will become one of the most important dependencies of Her Majesty's dominions."

Australia. Western Australia. Commerce. Minerals.

Besides these successful colonies, situated within the great southern or temperate division of Australia, there have been several attempts on the part of the British government to establish settlements on the north and eastern shores of tropical Australia, which require a brief notice. The first attempt was made by Captain Bremer, in H.M.S. Tamar, who, in company with two store ships and a party of military and convicts, established the stockade of Fort Dundas at Melville Island, in Lat. 11. 28. S. Long. 130. 30. E., in Apsley Strait. "This settlement, however, after an existence of four years, was abandoned on 31st March 1829, in consequence of the continued unfavourable accounts transmitted to the home government."[4] "The settlement of Fort Wellington was formed by Captain Stirling in H.M.S. Success, on the 17th June 1827, on the N.E. side of Raffles Bay, in Lat. 11. 14. S. Long. 132. 24. E., for the purpose of carrying on a traffic with the Malays, from Maccassar in the Celebes, who frequent the coast of Northern Australia in quest of the *Trepang* or sea-slug. This settlement was abandoned on the 29th August 1829, at a time when the objects for which it was formed were about to be realized."[5] On the 27th October 1837, a military post, with H.M.S. Britomart as tender, was established at Port Essington, "for the double purpose of affording shelter to the crews of ves-

Australia.

sels wrecked in Torres Strait, and of endeavouring to throw open to British enterprise the neighbouring islands of the Indian Archipelago." After having struggled unsuccessfully for twelve years to rear sufficient food for themselves, and having lost a number of their men through privations and hardships and the unhealthiness of the climate, the sappers and miners finally abandoned the settlement, named Victoria, on the 30th November 1849. In January 1847, the staff of a new penal colony to be called "North Australia," headed by Colonel Barney, R.E., settled on the shores of Port Curtis, on the E. coast of Australia beyond the Tropic of Capricorn. After five months' occupation, and an expenditure of upwards of L.15,000, the attempt was abandoned.

Retrospect.

Australia is the latest known portion of the habitable world. The coasts and countries that are now the most distinguished of its territory are also those that were the last added to its geography. Our contemporaries, who now enter their ninetieth anniversary, will serve to bridge for us, with the span of a single life, the interval that separates Cook's discovery of New South Wales from our time. Thus brief is the retrospect of Eastern Australia, whose shores for two thousand years, unknown to the civilized world, had reverberated only to the waves of the great Pacific. A mere handful of savages roamed heedless over a country of surpassing interest to science, and wonderful in results to the industry of its later occupants.

Progress.

Let us regard first the material elements. At the close of the year 1858 there were 1,099,926 colonists (exclusive of aboriginal population), consisting of 652,900 males and 447,026 females. The value of imports for the same year was L.27,000,000, and of exports L.21,250,000. Of the principal articles of export produce, gold, which is derived from Victoria, New South Wales, and New Zealand, amounted to L.11,211,250; copper, from South Australia, to L.373,382; wool, from all the colonies, to L.3,750,000; and agricultural produce, from all save Victoria and West Australia, to L.1,108,476. The annual public revenues, exclusive of loans, amounted to L.5,391,323, and the collective public debt, while we write (1859), is between eight and nine millions sterling. The banking statistics form an interesting comparison, from their relatively large figures, with those of this country. For the four chief colonies, New South Wales, Victoria, South Australia, and Tasmania, containing together a population of 1,028,500, the note circulation (L.1 and upwards, payable on demand), was L.3,209,796; the specie in the banks, L.4,758,995; the deposits, L.12,873,224; and the discounts and other advances of the banks, L.16,583,932. Our colonists have already erected large cities, and have ploughed and planted a thousand locations, while ten thousand ships annually enter and depart from their busy seaports. The electric telegraph now connects all South-eastern Australia and Tasmania, and 160 miles of railway are in operation, besides surveys, estimates, contracts, and an energetic progress towards nearly 500 miles more. All this is well.

Society and government,

Let us now take the higher subjects of society and government. These colonies now govern themselves, and they are practically as independent in their procedure as the imperial Parliament itself. The home government has given Australia free scope to create and re-arrange its own political institutions, and the colonists have promptly applied themselves to what is evidently a congenial duty.

decidedly democratic.

The Australian tendencies point to those democratic principles that give us essentially republican institutions, modified only by the loyalty everywhere prevalent to a great monarchic empire of our countrymen. Manhood suffrage, the ballot, no property qualifications, representation based on population, entire civil and religious equality before the state; these are the principles that seem, with remarkable facility and unanimity, to evolve from a society of our countrymen, thrown together upon a new scene, free from the traditions of place, and equalized together by the sense of one common object, namely, the attainment of independence and means by the medium of industry. A society may reasonably pride itself, that every independent and well-conducted member is a citizen, equal before the law in all political, civil, and religious rights. Such a status imparts everywhere a marked stimulus. Public questions become the common property of every rank. Constant discussion gives decision to individual and general views. Strong views and deep convictions comparatively disregard the inconvenience of change, and hence the restless aspect of the colonial picture. Democracy becomes the conservatism of colonies; and the interest in public affairs is not by any means to be measured by leisure from other pursuits or by the wealth or refinement of society.

Australia.

Second or upper chamber.

The new system is already developing these results, and that perhaps in somewhat strong relief, but they were not unforeseen. A second chamber of legislation, to secure a re-consideration to popular impatience, was provided by the foresight of each colony. If this colonial senate has been less conspicuous than was desirable, justice has scarcely been done it in the mode of constitution at the offset of self-government. Its case was decided on at a season of transition. At Sydney the constitution is by crown nomination, at Melbourne by election, under a most exclusive qualification of voters as well as members; neither plan having at all the effect of bestowing the maximum of influence with a colonial public.

The "constitutional system" at fault.

But in truth the "constitutional system" itself, although suitable to the quieter politics and particular case of the parent society, is in some striking points a disadvantage to the colonies. That slip-shod system of everlasting "change of ministry" has no really necessary existence, and its inconvenient and discrediting effects ought not to be chargeable on what are properly colonial institutions. It arises from the want of a real executive head, a position not permitted by free institutions to the governor, as he is an appointee of the crown without assent of the people. Hence an executive elective, but multiform and dominated by the popular assemblies; hence constant temptation to plotting and scrambling for office, with its open road through the fluctuating majorities. The question is a nice one, and the colonists may some day be desirous to consider it, namely, how to conjoin the popular assent with the royal nomination, and thus (if we may use the expression) normalize the democracy.

Federation question.

Another change may be even more important. Amongst the earlier questions of self-governed Australia was that of its future federation. Victoria led the way in this inquiry, and was at once seconded by New South Wales. Colonies, too, like individuals with flourishing incomes, must needs run into debt. Nearly nine millions sterling is already the public debt of these colonies. Railways and other works have irresistible attractions, and not less the facile practice of pledging posterity for their payment. Again, one administration will pledge everything to secure an economical triumph in financing for these outlays; but its successor will not perhaps hesitate an instant at the most radical changes in all the fiscal securities of the debt, whether of tariff or land laws. For the regulation of such interests, and as a check, gentle yet effective and recognised, to party extremes, class prejudices, and passing popular excitements, let us invoke federal Australia. The instincts of democracy and the genius of our countrymen are both, perhaps, equally understood. Any anxiety of the future is not for executive tyranny but executive weakness; and while we hail a federation, let it be an effective government over every question that has an intercolonial relationship, and especially a relationship to an external and observant world. (S. M.) (W—M W—H.)

AUSTRIA.

Austria.

THIS great empire is situated nearly in the centre of Europe, extending from the 44th to the 51st degree of N. Lat., and from the 8th to the 26th degree of E. Long. Its configuration is irregular, but its extent corresponds to that of Plate CII. an oblong of fully 600 miles in length from E. to W., and above 400 miles in breadth from N. to S. Compared with France, the Austrian dominions have a form nearly as compact, but their frontiers are by no means so strongly defined, nor so well guarded by physical barriers. France resembles a five-sided figure, having on three sides the sea, and on the other sides the Pyrenees, the Alps, and the Vosges; while in Austria the chief ranges of mountains are in the interior. In extent of surface, the Austrian dominions considerably exceed those of France, for they cover, including Cracow, incorporated into the Austrian empire in 1846, 256,958 English square miles. They comprise a remarkable diversity of tribes, and even nations, differing from each other in language, habits, religion, and comparative civilization.

The component parts of this great empire consist of six countries bearing each the name of kingdom, viz., Hungary, Bohemia, Galizia, Lombardy and Venice, Illyria, and Dalmatia; one archduchy, Austria; one principality, Transylvania; one duchy, Styria; one margraviate, Moravia; and one county, Tyrol. After the accession of the present emperor Francis Joseph, the various provinces of the empire received the title of *crown-lands*, twenty in number, and subdivided into minor districts. This new arrangement, however, must upon the whole be regarded as provisional, since the new constitution, in virtue of which Austria was to be transformed into one uniform empire, was, as will hereafter be seen, abrogated in the year 1851, two years after its promulgation.

We shall begin with an historical notice of this empire, showing, first, the means by which Austria, originally a small state, progressively rose into importance; second, the resources by which she withstood the reverses sustained in her long contest with revolutionary France; next, her condition and policy during the subsequent years of peace; and finally, the manner in which she came through the latest and most dangerous crisis in her history.

History.

The cradle of Austrian power was the fertile tract lying along the southern bank of the Danube to the eastward of the river Ens. It is said to have been overrun and partly colonized by Germans under Charlemagne; but be that as it may, after the empire of Germany was constituted in the ninth century, the district in question, afterwards called Lower Austria, was declared a military frontier for repelling the incursions of the Huns and other barbarous tribes to the eastward. It was called *Ost-reich*, the east country, from its position relatively to the rest of Germany; and its governor received from the head of the empire the title of margrave (in German *mark-graf*, or lord of the marches), which his descendants bore for centuries without anticipating the future greatness of their house. Towards the middle of the twelfth century their territory received an important accession in the province W. of the Ens, which, from its vicinity to the Alps, and the greater elevation of its surface, was called Upper Austria. The governors of this augmented domain were now raised by the emperors of Germany from the humble rank of margrave to that of duke; and it was one of their number, Duke Leopold, who, towards the end of the twelfth century, ungenerously detained our Richard I. in confinement on his return from the Holy Land. It was at this time also that the important province of Styria came to the dukes of Austria by bequest. Hitherto the ducal residence had been in a castle on the high ground of Kahlenberg, near Vienna; but it was now removed to that city. In 1246 the male branch of the ducal line, originally from Bamberg in Franconia, became extinct, and Austria underwent a long interregnum. The reigning emperor of Germany declared both that duchy and Styria to have lapsed to the imperial crown, and appointed a lieutenant (*statthalter*) to govern them on the part of the empire. But claims to the succession were brought forward by descendants of the female branch of the Bamberg line; and after various contests, Ottocar, son of the king of Bohemia, was, in 1262, duly invested with the government of Austria and Styria. Carinthia, Istria, with part of Friuli, soon after devolved on Ottocar by succession; but he forfeited all these advantages by his imprudence in refusing to acknowledge as emperor Rudolph of Hapsburg, who had been regularly elected to that high station. Hostilities ensued; the fortune of Rudolph prevailed; and, in 1276, Ottocar was obliged to renounce his title to Austria and its appendant states. Notwithstanding this renunciation, Ottocar re-entered Austria with an army, but soon after fell in battle. The ducal throne being then vacant, Rudolph vested the succession to it in his sons; and having obtained the sanction of the electors of the empire to that important act, the reign of the Hapsburg dynasty over Austria commenced in 1282.

Austria.

In the beginning of the following century the dukes of Austria lost a part of their Swiss territory by the insurrection of the cantons. This they never recovered; but in 1364 they acquired Tyrol; and Austria, hitherto known only as a remote province, little connected with the improved part of Germany, was soon after brought into contact with the general politics of the empire. The rank of emperor of Germany had been held successively by Saxon, Franconian, Suabian, and Bohemian princes, Austria having as yet supplied only one of the number (Albert I.); but, in 1438, another Albert, duke of Austria, was raised to that dignity, and, from close connection with Bohemia and Hungary, the power of Austria became so much greater than that of any other state in the empire, that from 1438 the imperial crown was regularly vested in the chief of the Austrian family. In the latter part of the century of which we are treating (the fifteenth), Maximilian I., an emperor of the Austrian line, made great additions to the power of his house by matrimonial connections, having himself espoused the heiress of the Netherlands, and afterwards married his son to the heiress of the crown of Spain. Of the latter marriage the issue was the well-known Charles V., who held the crown of Spain by inheritance, and the empire of Germany by election. In the third year of his reign (1522), Charles made over the German provinces to his brother Ferdinand I., who, in consequence of his marriage with Anne, sister of Louis II., king of Hungary and Bohemia, succeeded in gaining the crowns of these two countries. In 1555, Charles, whose ambition had appeared insatiable, all at once retired from his worldly career, leaving the German crown to his brother Ferdinand, and his other possessions to his son Philip II. Ferdinand, already king of Hungary and Bohemia, was elected emperor in 1556, and thus became the head of the Austrian Hapsburg line. The formidable power united in one dynasty, was thus split up by the very monarch who was its creator, though, even after its partition, both the Spanish and Austrian branch were still large enough to rank as first-rate powers. In Hungary, Ferdinand found a rival in Zapolya, elected king by the majority of the people; nor during his life could Ferdinand obtain possession of the whole country.

The general rule of the Hapsburgs, and especially the religious persecutions under the reigns of Rudolph II., Ferdinand II., and Leopold I., were productive of protracted and bloody wars, during which time the Turks made them-

Austria. selves masters of the greater part of Hungary, frequently assisting the malcontents against their Austrian masters. Ferdinand was succeeded by Maximilian II., his eldest son, whose successor was the dreamy and bigoted Rudolph II., subsequently compelled to resign his crown to Matthias II. In the year 1618, Ferdinand II., archduke of Styria, succeeded to the throne, after the death of his predecessor without issue. This emperor is well known by his sworn hatred against the so-called heretics, the Protestants, and scarcely had he commenced his reign when his cruelty against the Bohemians gave rise to the *Thirty Years' War*, one of the most remarkable events in modern history. On the one side were the Catholic princes of the empire, with Austria at their head; on the other, Saxony and the Protestant states, assisted at one time by Sweden, and subsequently by France. The most distinguished commanders were Gustavus Adolphus on the part of the Protestants, and, on that of the Catholics, Wallenstein, Duke of Friedland. Both were greatly superior to the age in which they lived, and evinced, at the battle of Lutzen, fought in 1632, talents not inferior to those displayed on the same fields in 1813. Wallenstein survived his illustrious opponent, but met a tragic end: having been suspected of treating with the Protestant princes for his own aggrandizement, a suspicion never afterwards verified, he, with some of the chief officers of his staff, was most cruelly assassinated by order of his imperial master. The war was at last ended by the peace of Westphalia, by which Austria was obliged to relinquish Lusatia to Saxony and Alsace to France.

The peace of Westphalia, like that of Utrecht in a subsequent age, restored tranquillity throughout Europe. It continued many years, and might have lasted much longer, had not the ambition of Louis XIV. alarmed the neighbouring states, and obliged them to look for safety in arms. Belgium, held at that time with a feeble hand by Spain, was the prize at stake; and the dread of that fertile and populous country falling into the power of France called forth the greatest efforts on the part both of Austria and of Holland, which, from the extent of its financial means, was at that time a power of great influence. Louis was surrounded by able generals and well-disciplined armies. Flattered with the prospect of success, he attempted the conquest of the Netherlands in no less than three wars, in two of which (those begun in 1672 and 1689) Austria bore a principal part. In the last she received the co-operation of England, which then, for the first time, came forward as a principal in continental coalitions, contributing largely both in troops and subsidies. The chief scenes of conflict were the Netherlands and the banks of the Rhine. The French, acting with all the advantage of unity, had frequently the superiority in action; but the allies, numerous and resolute, were never discouraged by defeat. At last, in 1697, came the peace of Ryswick, which left, as peace often does, the contending parties in nearly the same relative positions as at the outset of the contest. The allies had the satisfaction, however, of having compelled the aspiring Louis to stop short in his encroachments and schemes of aggrandizement.

But with so restless a prince at the head of a population of 20,000,000, peace could not be of long continuance; and, on the death of the king of Spain, Austria, England, and Holland, found it again necessary to take the field. The question now related not merely to the Netherlands, but to whether a French or an Austrian prince should succeed to the crown of Spain. Hence the name of War of the Succession, given to this long contest, which, beginning in 1701, lasted no less than twelve years. The superiority in military skill was now for the first time on the side of the allies. The Austrians and other Germans, assisted by Holland and England, were led to repeated victories by Eugene and Marlborough. France sent forth numerous armies, and showed, in Villars and Vendome, generals worthy of the better days of Louis; but in Italy and the Low Countries the allies were completely successful; and it was in Spain only that they failed. Such was the state of affairs in 1711, when the death of the reigning emperor unexpectedly took place, and the election to that dignity fell on his brother, who had been destined by the allies to the throne of Spain. The prospect of the union on one head of the crowns of Spain and Austria brought to recollection the ambitious projects of the Emperor Charles V., and inclined many who had supported the war from a dread of France, to consider the transfer of Spain to a grandson of Louis XIV. the less dangerous alternative of the two. This, joined to the change of ministry in England, the removal of Marlborough from the command, and the impatience of the Dutch under so long and burdensome a war, led to the peace of Utrecht, to which Austria, after urgent remonstrances with her allies, and fruitless efforts in the field, acceded, by a treaty concluded in the year after (1714) at Baden. Well might she give her assent to a treaty which transferred to her not only the Low Countries, but extensive possessions in both the north and south of Italy. Austria.

The emperor, anxious to confirm his authority in Hungary and Transylvania, now directed his troops against the Turks. The latter, who, during the space of 150 years, were in possession of the capital of Hungary, and of the greatest part of its territory, evinced considerable sympathy towards the Hungarians, whom they, on many occasions, proved ready to assist in their struggles against Austria. In fact the impotence of the Austrian rulers, as evidenced by their inability to expel the Turks from Hungary, and their readiness to appease the anger of the sultans by annual tributes, served only to keep alive in the Turks the ambition of rendering themselves masters of the Austrian capital. Accordingly, in 1683, the Mussulman host appeared before the walls of Vienna, and the capital was only saved by the appearance of the intrepid Polish king Sobieski, who would, no doubt, have found the Turks within its walls, but for the singular carelessness with which the vizier carried on the siege. This was the first serious check given to these confident barbarians. At a subsequent date Prince Eugene defeated them in several actions, and the peace concluded with them at Carlowitz, in 1699, by the intervention of England, secured to Austria a considerable accession of territory on the side of Hungary. Still that country continued divided and doubtful in its allegiance to Austria. Eugene led thither, in 1716, a part of the armies with which he had conquered in Italy and the Netherlands, and applied European tactics against the Turks with distinguished skill. The result was a series of splendid successes, and a treaty of peace highly favourable to Austria.

Such, however, was not the case in the last scene of the military career of Eugene, when, nearly twenty years after (in 1735), he headed the Austrian armies on the Rhine. The French had taken the field in support of the claims of Spain on the south of Italy. Austria was evidently overmatched in force; and England, guided by the pacific counsels of Walpole, declining to interfere, the result was a treaty, by which the emperor relinquished to Spain the contested territory in Italy.

In 1740 the death of the reigning emperor, Charles VI., brought to a close the male line of the house of Hapsburg, the succession devolving on Charles's daughter, Maria Theresa. The death of Charles became the signal for attack on his dominions by almost all the neighbouring powers; by Prussia, Bavaria, Saxony, and even by France. But England came forward to support the cause of Austria with a liberal subsidy, while the Hungarians, now united and loyal, recruited her armies. The aspect of affairs was soon altered the Bavarians were driven back; and the French, who had ventured to advance as far as Bohemia, were obliged to retire to the Rhine. Frederick II. of Prussia proved a more

Austria. obstinate opponent; and, as the interest of England and Holland called the Austrian forces to the Low Countries to maintain the great contest carrying on in that quarter against France, Maria Theresa was induced to subscribe, first in 1742, and afterwards in 1745, a separate treaty with Frederick, by which she ceded to him the chief part of Silesia. But the unprovoked attack of Frederick sunk deep in her mind; she watched an opportunity of revenge; and, in 1756, formed that coalition of powers against Prussia, which gave rise to a war of seven years, and to an extent of devastation such as Germany had not witnessed for more than a century. On one side was the whole Austrian force, aided by 80,000 French, and, at particular periods of the war, by the Russians and Swedes; on the other stood Prussia and England, numerically inferior to their antagonists, but managing their resources, and directing their military efforts, with all the ability that belonged to the character of Frederick and of Lord Chatham. On the side of the French there appeared no commander of eminence; but on that of the Austrians, Marshals Daun and Laudohn were generals worthy of being opposed to Frederick. After a number of battles and great alternations of success, both sides became tired of the waste of blood; and a contest, waged for a time with a rapidity of movement and an eagerness for conflict almost equal to those displayed in the French revolution, was marked towards its close by the cautious tactics of Turenne. At last, in 1763, a general peace was concluded, and the rival powers were left very nearly in the same position as at the beginning of the war.

From this time Germany enjoyed peace during thirty years. In 1778 the death of the Elector of Bavaria gave rise to pretensions on the part of Austria, which drew once more into the field the great Frederick, now grown gray in command. Austria opposed to him forces fully equal in number and scarcely inferior in discipline, but happily the campaign proved bloodless, each side anticipating a close of the dispute by negotiation. In that manner, accordingly, it ended; Austria being content with the cession by Bavaria of the frontier district, called the quarter of the Inn.

Maria Theresa had married Francis Duke of Lorraine, who was afterwards elected Emperor of Germany, but died in 1765. Their son, Joseph II., was then joined in the sovereign power with his mother; and, on her death in 1780, he became sole ruler. The princes of the house of Austria, disposed rather to follow than to lead, have seldom been the authors of political change; but the Emperor Joseph was imbued with all the ardour of a sanguine innovator. He gave a loose to this disposition after 1780, issuing a number of edicts, of which several were praiseworthy in their objects, but abrupt and premature in their operations, having besides set at defiance all the municipal and other authorities of the various provinces, under the pretence that he was the best judge of the wants of the country. He established general toleration in religion, abolished a number of monasteries and convents, dismantled various fortresses, and took steps for new-modelling the existing systems both of law and of national education. But his commercial legislation, based on the prohibition system, gave undoubted evidence of the narrowness of his views as a statesman. Had the public in his dominions been ripe, as in France, for a general political change, Joseph would have perhaps been hailed as a subverter of abuses, and as the author of general improvement; but the Austrians, attached to old usages, understood little of his plans, and merely received them with passive acquiescence, while the arbitrary manner in which his improvements were introduced could not fail to provoke hatred.. The actual effect was thus very limited, notwithstanding the example of new institutions in the United States of America, and soon after in France. But in Belgium the case was different: the contagion of the French revolution spread over the country, and produced a sudden rising against the Austrians. This unexpected revolt, and the chequered success of the war then carrying on against Turkey, are understood to have preyed on the sensitive mind of the emperor, and to have caused his death in 1790. Austria.

Leopold, the brother and successor of Joseph, had a very short reign, the crown devolving in 1792 on his son Francis II Francis had hardly succeeded to the throne when he found himself involved in a contest with France, the length and vicissitudes of which proved such as to cast into the shade all former wars between that country and Austria. The first important blow was struck in November 1792 at Jemappes, where the numbers and audacity of the French obtained a signal success. Next year the superior efficiency of the Austrian armies secured to them a temporary superiority; but, in 1794, the multitudes of Frenchmen brought forward by the energetic measures of the terrorists, and the talents of commanders such as Pichegru, Moreau, and Kleber, young in years, but full of enterprize and activity, led to the conquest of the Netherlands, and the retreat of the Austrians beyond the Rhine. France now offered to Austria a separate peace; but England engaging to furnish large subsidies, the emperor declined a treaty that would have involved the cession of Belgium. The French, determined to obtain this cession by force of arms, crossed the Rhine, in the autumn of 1795, with two formidable armies. Prussia had withdrawn from the contest, and allowed the whole weight of it to fall upon the emperor. It was then that the talents of Marshal Clairfayt, as yet known only to military men, became apparent to Europe at large. With numbers inferior to the two French armies collectively, he found means, by rapid movements, to concentrate a force superior to either singly, and drove them across the Rhine with great loss. Next year, however, the French, undismayed by failure, resumed the offensive, and crossed the Rhine again with two armies; one of which penetrated into the heart of Franconia, whilst the other overran Suabia and part of Bavaria. But these armies had not the means of affording each other ready support; they were separated by the Danube, while the Austrians were in possession of the bridges on that river, and could move within a smaller circle. They were thus enabled to repeat their manœuvre of the preceding year, by detaching a superior force against the French army in Franconia, and thus obliging it not only to evacuate the country it had overrun, but to seek safety beyond the Rhine. Such was also the case with the southern army of the French, although the retreat conducted by Moreau was the subject of general commendation.

But whilst in Germany success inclined to the side of Austria, the case was very different in Piedmont and Lombardy. In Piedmont, indeed, the war had long been carried on between the French and the allies without decisive success on either side. The opposing forces were nearly equal, and the mountainous nature of the country afforded so many strong positions, that there seemed no means of bringing the contest to a speedy termination. But all this was suddenly changed by the genius of one man. Buonaparte appeared on the scene, and in less than a month after receiving the command, defeated the allies in three engagements; obliged the court of Turin to make a separate peace; and, pouring his forces into Lombardy, drove the Austrians from every position in that country except Mantua. The strength of the latter place, however, bade defiance to the attacks of the French, and enabled the emperor to make repeated attempts for the recovery of Lombardy. No part of the war is more deserving of attention than this campaign; for none displayed in a more striking light the extensive resources of Austria, or the inventive genius of Buonaparte. Threatened in the end of July by an Austrian army of great strength, but which was imprudently

Austria. advancing in two bodies, he hesitated not a moment in sacrificing his artillery, that by sudden marches he might assail his opponents before they effected a junction. In this he succeeded; but his loss was heavy, and the Austrians were rather repulsed than defeated. Six weeks after, a repetition by Buonaparte of these daring movements was attended with decisive success. When apparently marching against the Austrian troops in Trent, he turned suddenly to the right, and advancing by a valley, reached the headquarters of their army before they were prepared. The result was a series of actions, which cut off the retreat of their main body, and obliged it to fly for refuge to Mantua. But ere two months had passed, the Austrians prepared another army, which Buonaparte marched to encounter as it advanced towards Verona, using in his despatch to Paris these remarkable words: *Il faut frapper l'ennemi comme la foudre, et le balayer dès son premier pas.* On this occasion, however, fortune was not favourable to him. He was worsted twice in action (on the 6th and 12th November); yet, far from being discouraged, he conceived the extraordinary plan of quitting his camp at night, and gaining the rear of that army which had twice repulsed him. He reckoned on the effect of a surprise; but his hopes were disappointed by the time unavoidably lost in attacks on the village of Arcole, which stood in his way. The main body of the Austrians had time to advance, and the result was a series of conflicts, attended with great loss on both sides.

Thus ended the campaign of 1796, sanguinary beyond example even in those days of blood, and not altogether conclusive in its results. Next year, however, the chances of war were no longer doubtful. The Austrians having reinforced their army, made a final effort to relieve Mantua; but Buonaparte having intercepted a despatch with their intended plan of operations, was enabled to make such a disposition of his troops as to ensure success; and the results were, the victory of Rivoli, the surrender of the force destined to relieve Mantua, and the complete expulsion of the Austrians from Italy. The French now crossed the mountain barrier, and advanced toward the heart of Austria. This, joined to the approach of their armies from the Rhine, obliged the emperor to conclude preliminaries of peace at Leoben, and afterwards a treaty proceeding on these as a basis at Campo Formio. This treaty involved the cession by Austria of Belgium and Lombardy, but gave her, in return, Venice and its dependent provinces, making an absolute loss in population of 1,500,000 souls.

This peace, however, proved only a truce. The absence of a portion of the French armies in Egypt, and the evident misgovernment of the directory, induced England to form a new coalition, and renew the continental contest early in 1799. The Austrian troops took the field, powerful equally in numbers and in discipline; and the French, commanded for the first time by inferior leaders, were driven back both in Germany and Italy. The arrival of Russian auxiliaries, and the talents of Suwaroff, bore forward the tide of success, until the autumn of the year, when increased levies on the part of the French, and a better choice of generals, began to turn the scale in their favour. The capricious Paul now withdrew from the coalition, and the Austrians entered on the campaign of 1800 with their own forces only. These proved, as formerly, insufficient to withstand the French, especially when the latter were commanded in Germany by Moreau, in Italy by Buonaparte. Battles, unfortunately too decisive, took place; the victories of Hohenlinden and Marengo led to the treaty of Luneville, and to the cession by Austria of almost all her Venetian acquisitions.

This peace, though not so short as the preceding, lasted only four years. In 1805 Austria and Russia, provoked by Buonaparte's aggressions, and stimulated by English subsidies, took the field with numerous armies; but the successive overthrows at Ulm and Austerlitz rendered peace again indispensable to Austria. It was obtained (6th August 1806) by the surrender of the remainder of the Venetian territory, of the Tyrol, and of various districts, comprising a sacrifice in all of three millions of subjects. Soon after these reverses, Francis II. renounced the title and authority of Emperor of Germany, and assumed the title of Emperor of Austria. Taught by repeated disasters, he remained passive in the great contest in 1806 and 1807 between France, Prussia, and Russia; but in 1809 the war in Spain having withdrawn a very large portion of the French force, he ventured once more to try his fortune in the field. The Austrian armies were numerous; but Buonaparte had still a powerful French force at command, and was aided by all the troops of the confederation of the Rhine. The Austrians, worsted in Bavaria, retreated to Vienna; and although temporary hopes were excited by their success at Aspern (21st and 22d May), they were blasted by the disastrous day of Wagram, and peace was again purchased by a sacrifice of territory containing more than three millions of inhabitants. Austria, now reduced to a population of twenty millions, remained in peace during the years 1810, 1811, and 1812; but when the disasters of the French in Russia once more raised the hopes of Germany, and brought friendly standards into Saxony, Austria took part with the grand alliance, and her troops bore a conspicuous part in the battle of Leipsic and the invasion of France. The definitive treaties of 1814 and 1815 reinstated her in all her former territories, except Belgium, and gave her substantial additions on the side of Italy. It must, however, be observed, that according to the new territorial division, as determined by the Congress of Vienna, the extent of the Austrian Empire was diminished by 400 German square miles. The public debt, as reduced in consequence of the state-bankruptcy of 1811, amounted to something above 500,000,000 florins (or L.50,000,000 sterling).

The subsequent history of Austria may be divided into two distinct periods. The first of these, beginning with the year 1816, after the definitive settlement of the negotiations of Vienna, and terminating with 1848, was, so to speak, one of comparative peace, especially with regard to foreign powers; the other commenced with intestine commotions and wars, resulting in the complete subversion of the Austrian states-machine, and has left the whole empire in a provisional and unsettled condition up to the present day These two periods we shall treat separately in their order

AUSTRIA FROM 1816 TO THE WAR OF 1848.

Prince Metternich, one of the most conspicuous personages among the diplomatists assembled at the Congress of Vienna, became, from this time, the uncontrolled director of the helm of the state. His policy, in which he persevered until the hour when he was hurled from his post by the movement of 1848, was based on the principles of legitimacy and strict conservatism. In conformity with the former, Austria ever proved ready to assist any acknowledged or legitimate prince against revolutionary movements, while her conservative policy rendered her averse to anything like progress or innovation. "The transition from an old state of things to a new is as dangerous as that from a new state to one which no longer exists. Both are productive of disturbances which must be avoided at any price." Such was the doctrine which Metternich proclaimed after the restoration of peace, and which became ever after the basis of the Austrian policy. To follow up this system in all its consequences, the Austrian government established a strict censorship, whose office was to watch over the home press and literature, and to survey the importation of foreign literary productions. The secret police, which received a thorough organization since the year 1820, had to perform the office of censor in the department of social conversation; its reports

Austria. serving to the government as a means of estimating the sentiments of the people. It is needless to observe, that this was not the best method for furnishing the cabinet with correct information as to the state of the public mind; for the people, knowing the system of espionage by which they were surrounded, either avoided conversing on political topics altogether, or, if at all adverting to such subjects, purposely expressed sentiments totally at variance with their real convictions.

At the new territorial division of Europe after the fall of Napoleon, Austria renounced her pretensions to Belgium for the acquisition of the Italian provinces, which she deemed more secure. A few years, however, sufficed to prove the fallacy of this policy. In 1822, when a rebellion broke out in Naples and Sardinia, the movement soon spread to Lombardo-Venetia; and the Austrian government, after having quelled the disturbances in her own provinces, deemed it necessary for her own security to put down, by force of arms, the risings in the other states of the Italian provinces. Ten years later Parma and Modena suddenly rose in rebellion, when, guided by like principles, Austria sent her troops to restore peace in the Romagna. In short, the Italian possessions have proved one of the most vulnerable points of the Austrian Empire.

The French revolution of July 1830, however, was the first external event after the Napoleonic era which deeply affected and embarrassed the commanding attitude of the court of Vienna. The very accession of Louis Philippe to the Bourbon throne was a sort of declaration of war against the principles of legitimacy; and though the recognition of the Orleans king by Great Britain led Austria to acquiesce in the event, and to follow the example of the court of St James, she had soon after to encounter various difficulties directly arising from this French revolution. Her first task was in Poland. Tired of Russian rule, the Poles, hoping to be supported by France, took arms to regain their independence, when Austria aided the Czar in crushing them. The second manœuvre was in Germany, to which the revolutionary impulse had been communicated from France. Here Austria acted in concert with Prussia in establishing some new restrictive laws with reference to the German Confederacy. But more important was the desire for reform simultaneously manifested in several of her own provinces, which, with the exception of Hungary, had been stript of all their ancient institutions and ruled by edicts from Vienna. As all the means of expressing public opinion were wanting, the government persevered with seeming confidence in its old policy, without encountering many obstacles; though in Hungary matters looked somewhat different. Deprived, equally with the other provinces, of the liberty of the press, Hungary retained its diets and county assemblies, institutions which gave ample opportunity for the expression of free opinion, and which, at the same time, operated as a check on the grasping power of the crown. The diet of 1832 loudly demanded the redress of old grievances, the states intimating their determination not to vote supplies till their wrongs were removed, and asking, moreover, the introduction of the Hungarian language into the courts of administration and justice instead of the dead Latin. Meanwhile the spirit of nationality awoke in Bohemia, the Czechs or Sclavonian party attempting to defend their nationality against the absorbing superiority accorded to the German element by the government.

In 1835 the Emperor Francis died, leaving the throne to his son Ferdinand. The mental weakness of this good-natured monarch, far from contributing to any change in the maxims of the state policy, served only to allow free scope to the omnipotent prime minister. "On the accession of the Emperor Ferdinand," says Baron Pillersdorf (the successor of Metternich), "the monarchy was not menaced by external dangers. Circumstances permitted an uninterrupted enjoyment of peace, but the necessity for internal ameliorations became, by so long a delay, more urgent, the demand for them more sensible; whilst, owing to the procrastinations of the government, faith and confidence were diminished. It is true that the prosperity of the provinces generally did not decline; on the contrary, many branches of commerce manifested an increase in their development; but in spite of this the situation of the whole empire inspired, in different respects, serious apprehensions, arising from the disordered state of the economy of finance, the yearly augmentation of the public debt, the inefficiency of the measures adopted, and still more from the oppressed disposition of mind of the clear-sighted and intelligent classes of the population. The Austrian Empire was partly surrounded by, and was thrown into manifold relations with, countries in which the constitutional form had developed itself in place of that which had previously existed; and as the defects of our own system had been publicly scrutinized and discussed, the spirit of constitutional freedom was transferred from without to the sentiments of all strata of the people. Contemporaneously with this arose a contrast, the more striking in the empire of Austria (the author here alludes to Hungary), where one-half of the people enjoyed thoroughly, during many centuries, a constitution, and consequently a right to participate in legislation."[1] These few remarks may suffice to show the state of Austria before the troubles of 1848. Under such circumstances the state of Austria necessarily became perplexed. In Germany she saw the rising influence of Prussia, whose free institutions and superiority in culture and science were gradually raising her to be the leading power of the German Confederacy; which very circumstance induced her to support the German element in her own dominions at the expense of the other nationalities. The non-German population were thus discontented with the court of Vienna for its Germanizing measures, while the Germans knew well that it was not Vienna which represented German learning and civilization. It may be remarked that the aversion of Austria to foster the development of the Sclavonic element in particular, was greatly owing to the apprehensions that it might lead to the ultimate advantage of Russia, which was continually endeavouring to attach to itself all the Sclavonic tribes. No Austrian statesman, in fact, was more alive to the encroaching power of Russia than Metternich. In 1830 Austria accordingly refused to join the rest of the European powers in the protocol which declared the independence of Greece; while ten years later, when Turkey was threatened by Mahommed Ali the pacha of Egypt, whose interests were loudly advocated by France, the court of Vienna readily joined England as an ally of the Porte. Both these instances prove of how much importance the integrity of Turkey appeared to Austrian statesmen with reference to the menacing attitude of Russia.

In 1846 the court of Vienna was again frightened from its sense of security by the Poles. Having suppressed this revolution, Austria, in concert with the other two powers which dismembered Poland, determined to blot out Cracow, the last remnant of Polish independence, from the map of Europe. This step, being contrary to the treaties of Vienna, was of course discountenanced by England, and more strongly remonstrated against by France. This disapproval, however, did not prevent the incorportion of that small republican territory with the Austrian empire; but it may safely be assumed that, if the question of the *Spanish marriage* had not for the time being occasioned a rupture between

[1] *The Political Movement in Austria during the year* 1848-9. By Baron Pillersdorf. London, 1850.

Austria. the cabinets of London and Paris, their conjoint interposition would not have been so utterly disregarded by the northern powers. Not satisfied with the advantages gained in Poland, Metternich thought fit to meddle with the internal affairs of Switzerland, which engaged his special attention from the circumstance of its vicinity to the Italian provinces of Austria. This country was at that time agitated by two contending parties, the Sonderbund, a Jesuitical party, and the Liberals. Metternich, who advocated the cause of the Sonderbund, succeeded in gaining over France to his side, coming into direct opposition to England, which gave its support to the party of progress.

THE REVOLUTION OF 1848, AND SUBSEQUENT EVENTS.

The French revolution of 24th February, which convulsed almost the whole of continental Europe, caused the Austrian empire to totter to its very centre. Scarcely had the intelligence of the fall of Louis Philippe reached Vienna, when that capital, proverbial for its carelessness about politics, presented all at once a counterpart on a smaller scale of Paris in the last days of Louis XVI. On the 13th of March the whole city was in a state of open rebellion; the populace, forcing the magistracy along with them, broke their way into the imperial palace, and loudly demanded from the Emperor Ferdinand the dismissal of his old counsellors and the immediate grant of a new charter. Three days afterwards an imperial proclamation was issued declaring the abolition of the censorship, the establishment of a national guard, and the convocation of a national assembly.

These measures, however, as well as the nomination of a new ministry, headed provisionally by Count Colowrath, and afterwards by Pillersdorf, (in place of Prince Metternich, who by this time was in full flight towards London,) were far from sufficing to arrest the popular movement, encouraged and led on by the students and other members of the university. The national guard just called into being, along with the academic legion, formed themselves into a permanent committee, and dictated laws to the government. The ministry, unable to resist, promised the convocation of a constituent assembly, while the emperor and the court fled from the capital and retired to Innspruck (May 17). The old system lay thus in ruins, its supporters or rather creators turned fugitives, while the prospects of a new organization were continually defeated more and more by the condition of the rest of the provinces. The Lombards and Venetians, already half in arms before the Parisian revolution broke out, were afterwards all the more determined to fight out their independence; and after having expelled the Austrian troops from Milan, they found an ally in Charles Albert, king of Sardinia, before whose arms the Austrian force under Radetzky was compelled to retreat. Meanwhile the movement propagated itself into Bohemia, where the Czechs, or Sclavonic party, determined to obtain redress against the Germanizing measures of the government. In a petition forwarded to the emperor, they demanded a united and independent national assembly for Bohemia and Moravia, independent municipal institutions, and in the distribution of public offices an equal selection from among the Sclavonians and German part of the population. Shortly afterwards the Sclavonian party in Prague, already in open collision with their German fellow-citizens, organized a club under the title of *Slowanska Lipa*, with the object of concerting common measures in the interest of all the Sclavonian inhabitants of the Austrian empire. A general summons was accordingly issued to the Sclavonians of the different provinces, calling upon them to send representatives to the Sclavonic congress to be held in the Bohemian capital. Delegates accordingly arrived, and the congress was opened in the beginning of June.

The people, who hated the Austrian commander, Prince Windischgratz, petitioned the emperor for his removal; meanwhile, however, a collision ensued between the Sclavonic militia and the regular troops, the result of which was the bombardment of the town and the final dispersion and imprisonment of the leaders of the Sclavonic party. Nor did matters wear a more peaceable aspect in Hungary. Here the national diet succeeded in carrying a measure for the abolition of feudality, as well as the appointment of a responsible and independent Hungarian ministry. These reforms soon gave rise to a civil war, commenced by the Sclavonians of Hungary, and, to say the least, encouraged by the Austrian government, which disliked to see an independent Hungarian ministry by its side. The imperial dynasty was thus menaced on every side. Austria.

In addition to this distracted and threatening state of affairs within the bosom of the empire itself, may be added the terrible blow inflicted upon Austrian influence on the side of Germany. The national assembly which met at Frankfort determined on the reorganization of Germany into one integral empire, excluding the German possessions of Austria from the confederacy, and offering, besides, the imperial crown to the king of Prussia. It was under these circumstances that the constituent assembly, composed of representatives from all the provinces of Austria except Hungary and Lombard-Venetia, was opened at Vienna by the Archduke John (July 22). It may easily be imagined that the Sclavonian element, largely preponderating over the German in these provinces, also greatly preponderated in that assembly; a circumstance the more distasteful to the government, in that its influence in Germany had already received so severe a blow, as already related. Notwithstanding, the aspect of affairs in Italy and Hungary, and the desire to flatter the Sclavonian population for the sake of its support, induced the government to allow free scope to this assembly in its schemes for the re-organization of the empire. But even whilst the assembly held its sittings, the committee of safety and the academic legion exercised, in many respects, the chief authority in the capital, which was the scene of repeated tumults until the month of October. At this period the people became incensed by the appearance before the walls of Vienna of a Croatian army, led on by the Ban Jellachich, who had previously been foiled in his attempts to advance upon Pesth. The popular fury became concentrated on Latour, the minister of war, who was known to have supplied the Ban with arms and ammunition for the invasion of Hungary. The war office was stormed by the people, after a severe conflict with the troops, when Latour was taken and cruelly murdered, his body stript of its clothes, and suspended to a lamp-post. After this event Windischgratz began to collect a large army, and soon after appeared before Vienna. The defence was carried on under the command of General Bem, a Polish officer, subsequently so distinguished in the Hungarian war. Windischgratz, however, conjointly with Jellachich, succeeded in storming the town (October 30). Among those who suffered death at the instance of Windischgratz was Robert Blum, member of the parliament of Frankfort, who was accused of having incited the people to rebellion. While Prague and Vienna were thus subjected by military power, the fortune of war began also to turn in favour of the Austrians in Italy. The Austrian government, which had been ready a few weeks before to relinquish its claims on Lombardy, and which implored the British cabinet to mediate a peace on the condition of its retaining only Venice, now saw Radetzky repel the Sardinian troops and re-enter Milan (August 1848). See LOMBARDY and SARDINIA. In Hungary, however, matters had now begun to assume a threatening aspect. By an imperial edict the diet met at Pesth (July 2), with the special purpose of providing for the safety of the country, when, on the other hand, it became notorious that the invasion of Hungary by the Croats, under Jellachich, was determined on by the Austrian government. This diet, therefore, after the

Austria. resignation of the Hungarian ministry in consequence of the double dealings of the court, appointed a committee of public safety, having previously voted a national army of 200,000 men. Meanwhile the court, then sitting in Olmütz, determined upon persuading the weak-minded Ferdinand to abdicate his throne in favour of Francis Joseph, son of the Archduke Francis Charles, Ferdinand's brother, and heir-presumptive to the throne. In a manifesto dated December 2. 1848, Francis Joseph announced his accession to the throne, promising to rule on the basis of true liberty, of the equality of the rights of the different populations comprising his empire, and indicating, moreover, his determination to suppress the rebellions then raging throughout his dominions. This announcement, as may be imagined, had the effect of still more powerfully rousing both Lombard-Venetia and Hungary. The former was henceforth the more determined to regain its complete independence, while the latter regarded the abdication of Ferdinand and the accession of his successor as unconstitutional, illegal, and null, inasmuch as it did not take place with the knowledge and consent of the diet. After a levy of recruits had been effected, the new emperor intrusted Windischgratz with the subjugation of Hungary, of which he was nominated civil and military governor. Joined by the Ban, Windischgratz broke into Hungary, and in a few days possessed himself of Buda-Pesth, the capital (January 1. 1849); the Hungarian diet meanwhile transferring its seat to Debreczin in Lower Hungary. After a short respite allowed to his troops, the Austrian general marched on towards the new seat of the Hungarian diet, but after the first battle, fought about the end of February, at Kapolna, Windischgratz, instead of advancing, was compelled to prepare for a retreat. The emperor, probably relying too hastily on the success of his arms in Hungary, dissolved the constituent assembly of Vienna which had been transferred to Kremsir, and, rejecting the constitution they were preparing, issued a self-granted (*octroyé*) so-called constitution (March 4. 1849).

This charter, meant to sweep away all the ancient institutions of the various provinces, proclaimed constitutional liberty, the responsibility of ministers, the liberty of the press, and other safeguards common in constitutional governments, as its groundwork. The establishment of a general diet in Vienna, and of provincial assemblies, and also of courts of central administration in the capital, were likewise among its more prominent provisions.

That Hungary could only see in this charter the abolition of its independent parliaments, and the subversion of all its ancient institutions, will be readily manifest; nor was Lombard-Venetia likely to be reconciled to Austrian rule by the proclamation of such a charter. In Italy, accordingly, the war continued, but very visibly in favour of the Austrian arms; and on the 23d of March 1849 the cause of Italian independence was crushed on the disastrous field of Novara, where the Sardinian forces were completely routed by Radetzky. But although Austria obtained so unexpected and speedy a triumph in Italy, its cause looked sufficiently desperate in Hungary in the spring of 1849. The Austrian army suffered one defeat after another in rapid succession, and were driven back, broken and dispirited, up to the vicinity of Presburg. Emboldened by the successes of its army, the Hungarian diet proclaimed the dethronement of the house of Hapsburg, and nominated Kossuth provisional governor of Hungary (April 24). In this emergency Francis Joseph applied for assistance to the Czar, which the Russian emperor readily granted, and the more so that his interference was objected to neither by France nor England. The Russian army, under the command of Paskiewics, was not long in penetrating into Hungary, and the whole war was at once extinguished by the disgraceful surrender of the Hungarian general Georgei to the Russian commander (August 13). See HUNGARY. Thus did the Hapsburg dynasty pass through a crisis more formidable than it Austria. had ever before experienced; owing its final preservation to the timely assistance of Russia, a power the increasing influence of which Prince Metternich, during his long administration, kept steadily in view and endeavoured to obstruct, but which, from the services it rendered, naturally assumed forthwith towards Austria the attitude of a protector.

To complete the summary of the events resulting from the movement of 1848, a few words must be said on the relation of Austria to Germany, subsequent to the war we have narrated.

Though the king of Prussia declined accepting the imperial dignity, tendered to him in 1848 by the diet of Frankfort, he concluded a treaty with the kings of Saxony and Hanover (May 1849), with the view of forming a *strict union* with the different states of the German Confederacy, to the exclusion of Austria. To this treaty, which is known by the appellation of the "Treaty of the Three Kings," the majority of the lesser states soon acceded, Prussia proposing, besides, to convene a diet at Erfurth under its own presidency, for the final settlement of the reorganization of Germany. This assembly was accordingly opened (March 1850), and obviously tended materially to raise the influence of Prussia at the expense of Austria, hitherto the leading power in the German Confederacy. But Austria, having now established her authority in her own provinces, began vigorously to counteract the efforts of her rival, and, on her part, invited the different states to send their representatives to Frankfort, where she assumed the lead. The legality of this assembly was at once acknowledged by Bavaria, always jealous of Prussian influence, as well as by Saxony and Hanover, which were subsequently gained over by Austria.

While these two parliaments were thus playing at cross purposes, disturbances arose in Hesse-Cassel. The margrave invoked the assistance of Austria, while the population, on the other hand, looked to Prussia for support. In accordance with the decision of the diet at Frankfort, Austria determined to march its armies into Hessia, a course of action opposed by Prussia and threatening immediate war between these two powers. (See articles GERMANY and PRUSSIA.) This conflict, which seemed unavoidable, was however averted by the conferences of Olmütz, Austria being represented by the prime minister Prince Schwartzenberg, and Prussia by Manteuffel. These deliberations ended in the entire humiliation of Prussia, which acknowledged the right of Austria to march its troops into Hessia, and even Schleswig-Holstein; a circumstance attributed, not without reason, to the influence of the Czar, with whom the Emperor of Austria and the Prince of Prussia held a conference at Warsaw (October 25. 1850), and who, as may be easily imagined, from his aversion to every species of innovation, pronounced in favour of the policy of Austria to re-establish the old *status quo* in Germany. About the close of the year 1850, Austria and Prussia convoked a congress of all the German states at Dresden, when the influence of the former so far preponderated, that Prussia, bent all the while on the reorganization of Germany, was fain to propose that the final solution of the affairs of the confederacy should be submitted to the decision of the old Frankfort diet. Having thus achieved so many triumphs over her rival, Austria now proposed to the diet of Frankfort the incorporation into the German Confederacy of all her provinces, including Hungary and Lombard-Venetia. This bold proposal, materially threatening the balance of power in Europe, was met by the remonstrances of the governments of France and England, though its failure may be more directly traced to the policy of Russia, which could not be supposed to look with indifference on the increase of power to the Austrian empire by the success of such a scheme of ambition.

Austria. *Population of the Austrian Empire according to the census of* 1846: *the Provinces classed by the comparative density of the Population.*

Provinces.	Population.	Inhabitants per German square mile.
Lombardy	2,670,833	7120

Tyrol	859,250	1746
The army	492,486	...
Total	37,443,033	

The increase of the population of the Austrian empire, since 1816, thus amounts to 10 millions. The approximate estimate of the population in 1852 is given by Hain in his last statistical work at 38 millions.

Such is the respective population of the different provinces of the empire. These differ so widely in climate, soil, language, and customs, that any general description cannot apply to the whole; we shall therefore describe the chief characteristics of those which form a part of the German Confederacy; for HUNGARY, LOMBARDY, and VENICE, the reader is referred to the respective heads of each, while Galizia will be found under that of POLAND.

AUSTRIA, THE ARCHDUCHY.

The archduchy of Austria consists of two nearly equal parts, viz., Upper and Lower Austria. The river Ens, flowing northward from the Alps to the Danube, intersects the archducal territory nearly in the middle; the country to the E. of the river being Lower, and that to the W., Upper Austria. Lower Austria, in particular the fertile tract adjoining the Danube above and below Vienna, formed originally the *nucleus* of that union of states which now constitutes the Austrian empire. That district is the seat both of the capital and of extensive manufactures, and is, in this respect, after the Italian provinces and Bohemia, the most important. Vienna itself, with its environs, produces silk, the manufacture of which is carried to a degree of considerable perfection, amounting in annual value to more than 12,000,000 florins. The other branches of industry consist principally of woollen, cotton, and hardware manufactures, the yearly value of which, added to the lesser fabrics of hardware, leather, glass, hats, and paper, is computed at three or four millions sterling. In the mountainous part of the province are mines of iron, coal, and rock-salt; but the wealth derived from these is slight compared with that resulting from the agricultural products of the more level part of the country. These consist of wheat, barley, oats, and other corns raised in England; and in the warmer situations of maize and vines. Advantage is taken here, as in Lombardy, of the numerous streams which flow from the mountains in the S. towards the Danube. They are used for irrigation, the great *desideratum* of the agriculturist in a warm locality. The produce of the land along the Danube, from Vienna to the Bavarian frontier, has been greatly increased likewise within the last half century by the use of marl. The traveller, in pursuing this track, sees in all directions a quantity of marl-pits, wrought with great activity; but still the crops raised are much smaller than they would be under a system like that of our improved lands.

Upper Austria, or the country W. of the Ens, was added to the sister province in the twelfth century; it is called Upper from its comparative vicinity to the Alps, and its greater elevation of surface. Its wealth consists not in manufactures, but in agricultural produce. It is too cold for the culture of the vine; but the low grounds are productive in corn, while the pasturages are extensive, both in the hills and the valleys. The sides of the mountains are covered with forests, the timber of which finds to a certain extent an outlet by navigable rivers, of which the chief are the Ens, the Salzach, the Traun, and the Trasen. One of the principal sources of employment to the lower orders in the forest-lands consists in felling their timber and conveying it to these rivers, whence it is floated to the towns along their banks, or to the Danube, the great channel for the transport of bulky commodities. Upper Austria, since the acquisition of Salzburg, has an extent (about 7500 square miles) nearly equal to that of Lower Austria; but in population it is far inferior, containing only 856,694 inhabitants, while the lower province reckons 1,494,399. Austria.

Population of the Chief Towns.

Lower Austria.		Upper Austria.	
Vienna	431,147	Lintz	26,618
Neustadt	12,862	Salzburg	17,009
Krems	8,700	Steyer	10,380

The early inhabitants of Austria are understood to have come partly from among the Germans in the W., partly from the Sclavonian tribes in the N. and E. German is now almost the sole language of the inhabitants, but it differs considerably from the German spoken in Saxony. As to religion, almost all the inhabitants are Catholics. Situated to the S.E. of Germany, and comparatively backward in civilization, Austria is considered as rather an outwork than an integral part of the empire; it was not until 1438 that the election to the imperial crown fell almost invariably on the head of the house of Hapsburg.

BOHEMIA.

Situation and extent. Bohemia, which ranks immediately after Hungary among the great members of the Austrian union, bears the title of kingdom, and is amply entitled to it by its extent, its population, and its progressive improvement. Backward as it still is, its resources, as the imperial government is well aware, are of a nature very different from those afforded by the mountainous provinces of the Alps, or the half-civilized districts on the side of Turkey. It is situated between the 48th and 51st degrees of N. Lat.; its form is an irregular square; its area, not yet accurately ascertained, is computed at fully 20,000 square miles, or three-fourths of the extent of Scotland. It is separated from the surrounding countries by ranges of mountains which encircle it on every side. From this, and from the general appearance of the interior, there seems little doubt that in an early age the chief part of Bohemia was covered with water, and that such continued the case until an outlet was opened at the northern and least-elevated part of the chain, in the direction by which the Elbe still flows, carrying with it the waters of tributary streams from almost every part of the kingdom.

This separation from the adjacent countries, particularly from the comparatively improved states of Saxony on the N. and Franconia on the W., necessarily operated to the disadvantage of Bohemia, and retarded its advance in civilization. German settlers resorted to it from time to time, but individually or in small parties, never in numerous bodies, or in such a manner as to disseminate extensively the improvements of their respective countries.

History. Of the aboriginal inhabitants of Bohemia there are no distinct accounts; but the name of the country confirms the current tradition that they were the Boii, a well-known Celtic tribe. Christianity appears to have been introduced

Austria. among them only towards the close of the ninth century, the era of the commencement of their historical records. The ruler or governor then bore the name of Grand Duke; and the succession under that, as under the subsequent title of King, was for a long time elective. In the thirteenth century Ottocar I., a prince of ability, passed laws similar to those which were enacted in England about the same time by Edward I., exempting the inhabitants of villages from dependence on the neighbouring barons, and enabling them to possess their little properties in security. His son and successor, Ottocar II., followed a similar course; a system of laws was compiled and reduced to writing in German; and Prague, the capital, became a town of importance. Bohemia was, as is well known, the country of the martyr reformers, John Huss and Jerome of Prague, who, at a date as yet too early, exposed the errors of the Church of Rome; for the public, not then enlightened by the art of printing, and the circulation of sound doctrines, misunderstood their views: a civil war burst out, and the result tended to perpetuate the abuses which these well-meaning men had laboured to remove.

The crown of Bohemia, like that of Hungary, had at different intervals been held from marriage connection by princes of the house of Austria; but in 1526 both crowns devolved on the head of that house, and have ever since been held by it in hereditary succession.

Climate and soil. The climate of Bohemia varies greatly, according to the elevation of the ground; the plains and valleys being warm, while the mountains, both in the S. and N., are cold and bleak. The annual fall of rain differs in like manner, according to situation; but 20 inches a-year is said to be a frequent average. The soil of Bohemia is in general good, but the agriculture is extremely backward. The chief products, as in a similar latitude in England, are wheat, barley, rye, oats, potatoes; also hemp, flax, and hops. In some warm situations, vines are cultivated, but as yet on a small scale. The pastures, on the other hand, are extensive, and in many parts as good as those of Saxony and Silesia; but the inhabitants are far behind their neighbours in the management of their flocks and the quality of their wool. In the rearing and training of horses considerable improvement has been made; studs having been established in different parts of the country by the Austrian government, which draws a large proportion of its cavalry from this quarter.

Forests, rivers. The forests of Bohemia are of great extent; and large quantities of timber are annually cut down and shipped in the parts adjoining a navigable river. The Elbe and Moldau are of great use for the conveyance of these as well as of other bulky commodities. The Elbe rises in the E. of the kingdom; but the Moldau, which at their junction is the larger river, rises in the southern extremity of Bohemia, and has a course of above 150 miles, nearly the whole width of the kingdom. The Eger, the river next in size, rises in the W., and has a course of about 100 miles, with a less rapid current than the Moldau.

Bohemia is divided into sixteen circles or counties, varying of course in extent and population, but containing on an average nearly 1300 square miles, and 270,000 inhabitants.

Population of the Chief Towns.

Prague	118,405	Pilsen	11,486
Eger	11,170	Budweis	12,311
Reichenberg	13,184	Konig-groetz	7,000

Besides these there are about fifteen petty places with 2000, 3000, or 4000 inhabitants each; but altogether, the town population, with the exception of the capital, is insignificant. That of the country is very different; it approaches in density to that of Ireland,—the farms being small, and the cultivation being carried on almost wholly by manual labour.

Austria. The manufactures of Bohemia have made considerable progress in the last and present age: they consist chiefly of woollens,—which are mainly produced in the town of Reichenberg and its environs,—of linen and leather; but they comprise also cottons, hardware, and glass. The glass-manufactories are principally situated in the mountainous parts of the province, and the largest emporia of these branches of industry are in the towns of Neuwelt, Silberberg, and Georgenthal. Besides the above, Bohemia is remarkable for the large number of its breweries, furnishing, it is said, the third part of all the beer produced in the empire. The annual value of the total industry of Bohemia is computed at 150,000,000 of florins. Great part of the woollen and linen is woven, as in the last age in England, in cottages. The mountains contain ores of iron, lead, tin, cobalt, and silver; but iron alone is extracted on a large scale. The foreign trade of Bohemia with Saxony and the north of Germany is carried on by the Elbe, on which, during the last few years, regular steam communication has been established; and the intercourse with the other Austrian provinces has been greatly extended by means of the different lines of railway recently established in the various parts of the empire. Austria. Manufactures.

The population of Bohemia has greatly increased in the last and present age. In 1791 it was considerably below 3,000,000. At present it amounts to 4,847,962. Of these about a third part are of German extraction, the other two-thirds being descended from the aboriginal stock. The ancestors of the Germans settled here from time to time, as mechanics, miners, and traders; employments which the uninstructed natives, like the cottagers of Ireland, were not capable of exercising. At present, even, it is by the German part of the population that whatever relates to public business or to foreign trade is conducted; the Bohemians generally confining themselves to husbandry in the country, or to common labour in towns. The middle classes, in general, speak both German and Bohemian; but the latter, a Sclavonic idiom, and quite different from German, is the only language of the lower orders, particularly in remote districts. The power of the sovereigns is as absolute in Bohemia as in any part of the Austrian dominions. The parliament or states consists of four classes of members; the clergy, the great nobility, the nobility of the second class, and the representatives of the chief towns. But their duties are little more than nominal; and the sphere of their vocation and authority does not extend much beyond executing the orders of the chief court of Vienna, and is almost confined to the collection of the taxes imposed upon them by the central government. They deliberate on the measures proposed to them by the royal commissioner, but they have no power to originate a bill. As to public revenue, Bohemia contributes fully two millions to the imperial treasury, and maintains a force in regulars and militia of 50,000 men. A few years before the war of 1848, the feeling of Sclavonian nationality began to manifest itself in this province in loud discontent against the Germanizing policy, and the bureaucratic system of the government. These manifestations exhibited themselves without restraint during the year 1848; and, as the government was in open war with Lombardo-Venetia and Hungary, were at first left unchecked, though, as the reader will find from the general history of the late war, the idea of Sclavonic nationality and independence was speedily silenced by martial law.

Moravia. Moravia, and Austrian Silesia, which is now annexed to it, contain an area of 11,000 square miles, with a population of 2,250,594, a degree of density approaching to that of England, and nearly double the average population of Germany. This is owing chiefly to the fertility of the soil; for although chains of mountains cross the country in several directions, the plains and valleys are extensive, yielding in abundance wheat, rye, oats, barley, and, in the warmer situ-

Austria. ations, vines. The pastures also are good, and a number of horses and horned cattle are exported annually. Here, as in Bohemia, the majority of the inhabitants are of Sclavonian descent; and the language of the lower orders is not German, but a dialect of the Sclavonic. Moravia resembles Bohemia in other respects,—in the religion of its inhabitants, who are chiefly Catholics; and in the limited power of its states or parliament, who deliberate on such subjects only as are proposed to them by the executive government. But it surpasses Bohemia, and every part of the Austrian dominions, except the Vienna district, in the extent of its manufactures and the use of machinery. Woollens, linen, and, since the beginning of the present century, cottons, are here made in large quantities, both for home consumption and export. The chief seats of the manufacture of cloths and other woollen goods are Brünn and Iglau. The manufacture of linen fabrics is carried on in Schönberg, Tribau, Sternberg, and Brünn. An article of recent production, and promising much success, is the manufacture of beet-root sugar.

Austrian Silesia has an area of 1900 square miles, with a population of 467,420. It consists of two circles or counties, called, from their respective chief towns, Troppau and Teschen; but, for the administration of justice and other public purposes, Austrian Silesia is considered as united with Moravia. It resembles that country, too, in the activity of its productive industry. The density of its population is owing less to an advanced state of tillage than to extensive manufactures of linen and woollens; the former, as well as the manufacture of thread, obtaining much celebrity. Of no less importance are the iron trade and the manufacture of hardware. The pastures of this country are in general rich, and the export of wool, already considerable, is likely to increase.

THE ALPINE PROVINCES.

Styria. The duchy of Styria, one of the earliest acquisitions of the Austrian family, has an extent of nearly 9000 square miles, with a population of 1,023,153, of whom more than half are of German descent, while the remainder are Wends or Sclavonians. The inhabitants differ in language, but are agreed in religion, being almost all Catholics. Styria bears a resemblance to the adjoining province of Carinthia, both in soil and climate; Upper Styria being very mountainous, while in Lower Styria the ground has less elevation as it recedes from the Alps. Hence a corresponding difference in temperature and products; the mountainous part being covered with forests, and fit only for pasture, while the plains and valleys produce wheat, barley, oats, rye, and, in the warmer situations, maize. The culture of potatoes, though introduced less than a century ago, has now become general, and has been the means of adding largely to the population. The mines are extensive, particularly those of coal and iron; the steel of Styria is as noted in Germany as the Swedish steel in the north of Europe. Salt also is obtained here in great abundance. Styria produces many articles of iron manufacture, among which may be chiefly noticed its excellent scythes and reaping-hooks; and the government founderies at Maria Zell and St Stephen are deserving of particular mention.

Tyrol and Voralberg. Tyrol bears in official papers no higher name than that of county (in German *Graf-schaft*); but it is by far the largest county in Europe, having an extent of above 15,000 square miles, with a population of 866,078. It is traversed in every direction by mountains, many of them of great height; while the low grounds consist, not of plains of any extent, but of a succession of long valleys to the number of more than twenty. In these the climate is comparatively warm, and the soil in many parts fertile, producing corn in considerable quantity, and, in favourable situations, vines. The ploughs and agricultural implements used in this country are extremely rude; but the inhabitants show both ingenuity and industry in cultivating slopes and summits, wherever there is enough of soil to reward their labour. In this mountainous region waterfalls are frequent, and many of them are made available for the movement of mills and other machinery. Mineral ores are found in Tyrol to an extent that justifies the expectation that they may eventually be made to afford considerable employment and income to the inhabitants; but in a country so rugged in its surface, and so deficient in machinery, little progress has as yet been made in working mines. Manufactures are equally backward; the work required for them, whether spinning, knitting, or weaving, being almost all performed by the hand. Southern Tyrol partakes more of the character of the Italian provinces, and has recently made great progress in the manufacture of silk goods, as also of leather. Austria.

The domestic animals in Tyrol are, in general, of a diminutive size. The forests contain wolves, bears, goats, and many other animals in a wild state; hence the number of the Tyrolese *chasseurs* or sportsmen, and their dexterity as sharp-shooters, so frequently evinced in the late wars. The Tyrolese, though of a warlike character, and strongly attached to the house of Austria, dislike the restraints of discipline. They perform, however, militia duty, and are called out for training during several weeks in the year.

The language of the Tyrol is German. Like the other provinces of the Austrian empire, it had its states or parliament, composed of deputies from the clergy and nobility, to whom there have been added, for some time past, deputies from the peasantry. It is needless, however, to observe that the functions of these states have always been much more nominal than real.

Carinthia. Carinthia adjoins Tyrol, and, like it, consists of a succession of mountains separated by narrow valleys. It contains a number of lakes, formed, as in the highlands of Scotland and other mountainous countries, by water collecting in hollows, and finding no outlet, except at a considerable height. Tillage is here on a very limited scale; but the pastures are more extensive, and the forests which cover the sides of the mountains would be very valuable, were it practicable to convey the trees to a navigable river. The mines of this province are extensive, particularly those of iron, lead, and quicksilver. The extent of Carinthia is 4000 square miles; its population 316,224. The chief towns are Clagenfurth and Villach. As in the case of Styria, the manufactures of Carinthia consist chiefly of hardware. The most profitable branch of industry, however, is that of sugar-refining, which flourishes most at Laibach.

Carniola. Carniola, the adjacent province, is more populous than Carinthia; because, though mountainous in the north, it has in the south extensive valleys and fertile plains. Here are also a number of mines of iron, lead, and quicksilver. The agricultural products are not merely wheat, rye, and barley, as in Carinthia, but maize and vines, the sure indication of a warmer sun. Of a population of half a million, only a tenth part are of German descent; the rest are Sclavonians. Carinthia, Carniola, Istria, and part of Friuli, form the present kingdom of Illyria.

Dalmatia. Dalmatia, though dignified with the title of kingdom, is a long, narrow, and, as yet, thinly peopled tract, extending along the east shore of the Adriatic, from Lat. 42° to 45°. It comprises the whole of what was formerly Venetian Dalmatia, along with the smaller territories of Ragusa and Cattaro. Its extent is about 6000 square miles; its population, 418,063. One of the chief occupations of the working population is ship-building. Its agricultural products, maize, vines, olives, and silk, give proof of a climate considerably warmer than in any of the above-mentioned provinces. Here, as in those provinces, the ranges of mountains are extensive; but there are also beautiful and fertile valleys. The iron mines and the marble quarries of Dalmatia are both of great

Austria.

extent; but as yet they are little wrought, on account chiefly of the thinness of the population. Such parts of the forests as adjoin navigable rivers, or have ready means of conveyance to the coast, are made available for ship-building; the Austrian government adopting the views of Buonaparte in considering Dalmatia of great importance towards forming a navy. No part of Europe abounds more with good harbours than the mainland of Dalmatia, and the numerous islands along the coast.

Physical Aspect, Soil, and Climate.

Rivers.

Of the rivers in the Austrian territory, by far the most interesting is the Danube. Before entering the imperial dominions, it receives a number of rivers flowing northward from the Alps, of which the principal are the Inn, the Iser, the Iller, and the Leck. It next receives the Ens, and flows eastward with a full stream, varying in breadth from a quarter to half a mile. It is bordered throughout this part of its course by high grounds or ridges of mountains, the distance of which from the water is generally greater on the south than on the north side. It is of sufficient depth to bear barges and large boats throughout the whole Austrian territory, and in Hungary it admits vessels of considerable size. Its navigation, however, is not easy, its banks being in various parts steep and rocky; while in the level countries, in which its waters are more widely spread, its bed is often encumbered with shoals. In the year 1830 a Danubian Steam-Navigation Company was established, which in 1848, possessed already more than thirty steam-vessels, which gave an unusual stimulus to commerce. The Danube, as connecting Austria with Turkey and the East, countries which produce no manufactures of their own, might undoubtedly be the means of greatly increasing the foreign trade of Austria, were it not for its restrictive and prohibitive commercial system.

The other great rivers in the Austrian dominions are the Save, the Drave, and the Muhr, which convey to the Danube the waters from the eastern face of the Alps. The Marsch or Morawa brings to it the tribute of Moravia, while the still larger streams of the Theiss and Maros collect all that flow from the southern side of the Carpathians. All these rivers abound with fish, and are of sufficient depth to be navigable; but flowing through poor and thinly-peopled countries, they have as yet been of little use in a commercial sense. A few years ago the Theiss was in part rendered navigable for steamers, an improvement for which Hungary is mainly indebted to Count Széchenyi.

Lakes and marshes.

Lakes and marshes are both numerous and extensive in the Austrian dominions. In Styria, Tyrol, and other mountainous tracts, they are formed, as in the highlands of Scotland, by water collected in valleys which, from the structure of the ground, are pent up in all directions. In Hungary, Galizia, and other level countries, their origin is different: they are a consequence of neglect of drainage, and of that backward cultivation which prevails in almost all countries until population and agricultural improvement attain a certain height. It was thus that marshes, heaths, and forests covered the surface of England in former ages, and that large tracts are at present lost to every useful purpose along the banks of the Danube, the Theiss, the Drave, the Save, and other rivers in Hungary, which inundate the country, when swelled by heavy rains or the melting of the snow. To drain these low-lying tracts would require skill, capital, and machinery, and, above all, the countenance of the central government at Vienna; all of which, however, have been hitherto wanting in these poor and backward countries.

Mountains.

The other striking physical features of the Austrian territory are successive chains of mountains, viz. the Alps in the S.W., and the Carpathians in the N.E. of the empire, all of great height and extent. In the bleak climate of Norway the higher parts of mountains present little else than continued sterility; but in the central and southern parts of Europe vegetation is seen to rise to a great height. The base of a mountain is often covered with vines and maize; the ascent with green pastures, or with wheat, barley, and similar kinds of corn. The trees in the lower and middle region are often the oak, the elm, or the ash; while, in the approach towards the summit, the yew and the fir are chiefly seen to brave the fury of the tempest. Many parts of Tyrol, Styria, Carinthia, and Carniola, abound with picturesque views, and recal to the traveller the scenery of Switzerland. Styria, in particular, has, like that country, its cascades, its glaciers, its perpetual snows, and its tremendous avalanches.

Austria.

Climate.

German writers are in the habit of dividing the climate of the Austrian empire into three regions or zones, viz. the northern, situate between the 49th and 51st degrees of N. Lat., and comprising nearly the whole of Bohemia, with the high-lying parts of Hungary, Moravia, Galizia, and the Buckowine; the whole extending over a surface of 70,000 square miles. The weather in these countries, though colder in winter and warmer in summer than in England, bears, in its average temperature, a considerable resemblance both to our climate and to that of the north of France. In products also there is a remarkable correspondence; wheat, barley, oats, and rye, forming the great bulk of the yearly crops. The middle region of the Austrian dominions is considerably more extensive; containing the whole of Lower Austria, with the chief part of Upper Austria, Moravia, Hungary, Transylvania, and Galizia. It extends along the entire length of the empire, and has a surface of fully 150,000 square miles. This vast tract lies beween Lat. 46° and 49°. The summer and autumn heats are here much greater than in England; and, in addition to wheat and other products mentioned above, vines and maize are cultivated in favourable situations, as in the middle part of France. Lastly, comes the southern region, extending from Lat. 46° to 42°, and comprising Lombardy, the Venetian States, the coasts of Croatia and Dalmatia, with the southern line of Sclavonia, and the Bannat of Temesvar. In these different countries the winter lasts during two or three months only, and the cold seldom exceeds that of our month of March. Here are raised not only maize and vines, but olives, myrtles, and other southern products, as in the south of France. This temperature extends over a surface of from 30,000 to 40,000 square miles.

We have stated these distinctions of climate according to latitude; but it is proper to add, that in no country does there exist greater difference of temperature in the same latitude, in consequence of the very marked differences in the elevation of the soil; one line presenting a succession of mountains, and another of plains and valleys. Thus, the Alpine Provinces, with the extensive tracts adjoining the Carpathian range, and the lofty barrier between Bohemia and Moravia, partake of all the rigour of the north, though situated to the S. of Lat. 49°; while Galizia and the interior of Bohemia, though to the N. of that line, are considerably warmer, because their surface is in general even, and little elevated above the level of the sea.

The average fall of rain is considerably greater in the mountains than in the plains. In Vienna, and the low-lying tracts generally, 28 inches are a frequent average for the year; but in the mountains it often amounts to 40 inches and upwards.

From its geographical position, the summer heats in Austria are considerably greater than in the same latitude in England, while the cold of winter is often more intense. In this country, and still more in Ireland, the vicinity of the ocean induces a frequency of rain, with a medium degree of heat and cold in the prevailing winds, which by no means exist in Poland, Austria, or any country in the interior of the continent. But the transitions from heat to cold, and *vice versa*, are in many parts of Austria as frequent and as remarkable in degree as in this country.

Products, Manufactures, and Trade.

Mines and minerals. In a country covered in so many parts by mountains, the extent of mineral produce can hardly fail to be large. Iron ore is abundant in many parts of Bohemia, Upper Austria, Styria, and Carinthia; and if the quantities of tin or copper hitherto wrought in these provinces be comparatively small, it is owing to the fact, that most of the mountain districts are as yet imperfectly explored. The mines already wrought in Bohemia afford good tin, and those of Hungary excellent copper. In the latter country, particularly at Schemnitz and Kremnitz, are rich mines of gold and silver, partly the property of government and in part of private individuals. The aggregate value of the mines and minerals belonging to government amounts to 4,457,135 florins, and of those which are private property to more than 13,000,000. In this computation Hungary and Transylvania are not included. The respective quantity of the more important metals and minerals belonging to the government, as obtained in 1847, was as follows:—Copper, 2753 cwt.; lead, 1418 cwt.; zinc, 3360 cwt.; raw iron, 494,089 cwt.; cast iron, 58,043 cwt.; iron vitriol, 12,136 cwt.; cobalt, 300 cwt.; sulphur, 13,238 cwt.

Coal mines. A far more important mineral than silver ore, namely coal, has been found in many parts of the Austrian dominions,—in Bohemia, Moravia, Austria Proper, Hungary, and Styria; but the quantity raised is large only in situations contiguous to a navigable river. One of the main sources of the superiority of England to other countries, has been the ease of conveying coal in former ages by sea, and latterly also by canals and railways, to situations where fuel is of importance for manufactures. But in a country like Austria, which has no coast, where canals are almost unknown, and railways have been heard of only of late, the opportunities of such conveyance are as yet very rare. This, joined to the abundance of wood fuel, has prevented the working of many coal mines; but they bid fair to be a source of general employment to the lower classes, and of advantage to those who manage them, when manufactures shall be conducted on a larger scale, and the communications assimilated to those of England or the Netherlands. The whole amount of coal belonging to government was, according to the official computation of 1847, 158,219 cwt., and that belonging to private individuals exceeded 14,000,000. It may be stated that in Hungary the produce of the government coal pits is nearly fourfold that of all the rest of the empire as above given.

Salt mines. Similar observations apply to the raising and distributing of rock salt, mines of which are found in various parts of the empire. Those of Bochnia and Wieliecka in Galizia are known to be the greatest in Europe. A number of others are found along each side of the great Carpathian range, and may be said to extend with greater or less intervals all the way from Moldavia to Suabia. This very extensive tract comprehends the salt mines of Wallachia, Transylvania, Galizia, Upper Hungary, Upper Austria, Styria, Salzburg, and finally of Tyrol. They are found either at the base or on the ascent of great mountains, the salt extending in horizontal or undulating strata, and alternating with strata of clay. The total produce of salt was in 1847 as follows:—Rock salt, 3,060,850 cwt.; boiled salt, 2,050,362 cwt.; sea salt, 522,726 cwt.; total, 5,633,938 cwt.

Agriculture. Austrian agriculture has made, so to speak, no progress whatever during the last thirty years, and continues in a very backward state in all parts of the empire, with the exception of the Italian provinces and the archduchy of Austria itself. The reasons of this backwardness are very obvious. While France, likewise an agricultural country, issued from the great Napoleonic war with a free population, feudality continued in Austria down to the year 1848; a circumstance in itself sufficient to cripple the agricultural produce of the country, and still further enhanced by the protective policy of the government towards manufactures; a policy which, while it tended on the one hand to turn all the capital of the country into the channel of the manufacturing interest, compelled the agriculturist, on the other hand, to purchase home-made implements that might have been procured abroad at a cheaper rate and of a better quality. To these two causes may be added the existence of a large standing army, and the long period of military service customary in Austria, which bereft the rural population of the stoutest of its labourers. Farther, the absence of personal liberty and the right of free discussion, elements the most important towards the increase of national wealth, have also unavoidably contributed to the same result. In addition, it may be stated that the Austrian population have hitherto remained in complete ignorance of the modern scientific and practical improvements in agriculture, adopted by the other nations of Europe. Nowhere, however, is there a fairer field for improved husbandry, for no part of Europe presents a greater extent of good soil. Lower Austria has, like Lombardy, the advantage of extensive plains watered by streams flowing from a range of mountains which form the background of the prospect contemplated by those who travel along the banks of the Danube. Moravia has a similar climate, and almost equal advantages of soil and position. Galizia is likewise fertile, the most so perhaps of any of the Polish provinces; while in the S. and E. of the empire, many of the plains of Hungary and Transylvania might be rendered productive were the population more dense, and acquainted with the method of draining, irrigating, and properly tilling the ground. The land of second-rate fertility is in the Alpine provinces. The slopes of the mountains, up to a certain height, are favourable to pasture, and the raising of oats and other like grain; but in many parts the height is so great as to outweigh the advantage of latitude, and to confine the inhabitants to a scanty return for their labour.

Comparative culture of Great Britain, France, and Austria, exhibited in proportions of 100.

	Great Britain and Ireland.	France.	The Austrian Empire.
Land under tillage	34	44	34
Vines, orchards, gardens	1	5	3
Land in grass, whether natural or sown	40	14	17
Forests, plantations, copses	5	17	26
Poor land, as heath, marshes, commons; also land totally unproductive, as rocks, summits of mountains, lakes, beds of rivers, roads	20	20	20
	100	100	100
Comparative population. Inhabitants per square mile	220	165	130

This table suggests several conclusions of importance. First, the proportion of land altogether uncultivated is nearly equal in the three countries; the mountains of Scotland, the bogs of Ireland, and the commons of England, containing a surface corresponding to that of the high mountains in the Alpine provinces of Austria, and the marshes and sandy levels of Hungary. But the proportion of land covered with forests, and thus lost to useful cultivation, is far greater in France, and still more in the Austrian empire, than in this country. The inducement to convert such land into pasture is far greater in Britain and Ireland, in consequence of our numerous population, and the high price of butcher-meat, wool, and hides. To this is to be added a very different consideration, viz., that the facility with which all our large towns are supplied with coal makes it quite unnecessary to keep up forests, as on the continent, for the purpose of fuel; and

above all, the high value of arable land in England, owing chiefly to the density of the population.

Land under tillage.

Next, as to the land under tillage, the great proportion of such in France is owing to the lower orders living almost wholly on bread and vegetables, to the exclusion of animal food. In Austria the proportion of land in tillage is equal to that in Great Britain; but there is the greatest difference in the nature of the cultivation, the produce in even the best districts of Lower Austria being thirty per cent. less than would be obtained from similar soils in this country. In the nature of the produce there is a considerable resemblance; the bulk of it in either country consisting of wheat, barley, oats, rye, pease, beans, potatoes, along with flax and hemp. Of rye, the proportion raised is larger in Austria; that of potatoes much smaller. Maize is raised in the southern provinces of Austria, as of France, and is said to yield much more nourishment for either men or horses than could be obtained from wheat on a similar soil.

The total cultivated soil of Austria amounts, in round numbers, to 54,000,000 *hectares*, that of France to 38,000,000; while that of Britain is not above 25,000,000; while the estimate of the comparative *value* of the agricultural *produce* of the three countries gives the following remarkable result:—

Approximate value, in francs, of agricultural produce (not including live stock), in Britain, France, and Austria.....	Britain.	France.	Austria.
	6,900,000,000	4,000,000,000	3,000,000,000

Vines.

The northern parts of the empire, viz. Bohemia, Galizia, and part of Moravia, are too cold for vines; but in the central part of the empire they are cultivated extensively, and wine is sold in large quantities for home consumption. The prices of the different qualities vary from sixpence to one shilling a bottle. The port is far inferior to that obtained from France, in consequence chiefly of the want of conveyance. Lower Austria and Hungary, the fittest countries for the vine, have navigable rivers only to the eastward, and these lead to countries which either raise wine for their own use, or are too poor to make purchases from their neighbours. The exports from the Austrian states are thus limited to small quantities of choice wines, such as the well-known Tokay, which is raised on the last chain of the Carpathians, near the district of Zemplin. This wine is cultivated along a tract of about 70 square miles: its qualities are various; the richest kind proceeding from the grape with little or no pressure; while the inferior sort is said to be made from the dried grape, reduced into a sort of pap, and mixed with other Hungarian wines. But it by no means follows that all the wine sold under the fashionable name of Tokay is the product of the district in question; for even in Vienna there is not perhaps a tenth of real Tokay among the wines which bear that name.

The total produce of wine is estimated at more than 27,000,000 *hecatolitres*, of which 22,000,000 are supplied by Hungary alone. This evinces certainly a degree of abundance in that article, though it is much inferior to the quantity raised in France, which is computed as above 40,000,000 *hecatolitres*.

Manufactures.

Manufactures have in the last and present age received considerable extension in the Austrian dominions. They are still, however, on a footing very different from those of our country. In England they are generally conducted on the plan of particular towns or districts restricting themselves to specific branches; as Manchester to cottons and Birmingham to hardware. Hence our minute division of employment, our nicety in workmanship, and the surprising quantities produced. But in Austria the case is different: woollens, linen, hardware, and of late years cottons, are made in almost every place of considerable population; a sure proof that their establishments are on a small scale, and that they avail themselves very imperfectly of local advantages or of the division of labour. In many parts, indeed, weaving and other sedentary work is performed in cottages, as was the case in England a century ago. Spinning wool and flax has from time immemorial been the habitual employment of the lower class of females in Germany; and still continues to be so, notwithstanding the competition of machinery. Silk is most largely manufactured in Vienna and the Italian provinces. Linens are woven in every province of the empire; but the finest qualities are made in Lower Austria, Moravia, and certain parts of Bohemia. These countries supply little for export beyond the limits of the empire, but a great deal to the adjacent provinces. Woollens also are a very general manufacture throughout the empire. As to hardware, the mines in the mountainous districts supply an ample store of materials, the manufacture of which takes place partly on the spot, partly in the larger towns, such as Vienna, Prague, and Karlsbad. Bohemia is celebrated for the number of its glass works, a consequence of fuel being cheap in several districts which have the advantage of water conveyance. Hungary, Transylvania, and the Buckowine, having extensive pastures, as well as forests containing vast herds of cattle in a wild state, hides are an article of export from the same cause as in the thinly-peopled provinces of Russia or the wilds of Buenos Ayres. The most important articles of export, however, are corn, wool, wine, and cattle. Paper also is made to a considerable extent in the Austrian states, in consequence of the cheapness of linen rags.

All these are manufactures of old date; but cottons are comparatively of recent introduction, and are confined to Vienna and some of the principal towns; as is also the refining of sugar, which has lately received a great impulse. The cheapness of labour is in favour of such undertakings in Austria. One of the chief obstacles, up to a recent date, was the distance which the raw material, whether landed at Trieste or Hamburg, had to be conveyed by land, a disadvantage now partly overcome by the establishment of several lines of railway.

Comparing these different manufactures with those of an improved country like England, we find the foreign articles generally higher in price and more homely in appearance, but at the same time more durable than ours. This distinction is found to hold in regard to fabrics the most different in their nature; the muskets made in Germany and France being heavier, exactly as their woollens, cottons, and linens, are thicker than ours. Lightness of workmanship and despatch in completing an article are the result of long practice: the comparatively limited experience of foreigners, and their imperfect subdivision of work, require both longer time and a larger consumption of raw material.

Foreign trade.

In her intercourse with foreign countries, Austria experiences all the disadvantages of an inland position, and of a very limited access to the sea; the portion of coast belonging to her being in a corner of the empire. Its extent is about 500 miles, comprising the north and east shores of the Adriatic, from the mouths of the Po on the west, to Ragusa and Cattaro on the east. The commercial seaports are Venice, Trieste, and Fiume; the first being the inlet to Friuli and Lombardy, the second to Carniola, and the third to Croatia. From Venice the access to the interior is easy, the country being flat, and admitting of intersection by canals; but Fiume, and still more Trieste, have to the east ranges of mountains, over which the transport of bulky commodities is attended with great labour and expense. It must be remembered, moreover, that the Austrian tariff was the highest in Europe up to the year 1848, and that many articles of manufacture, such as rock-salt, rouge, gold-dust, and tobacco, were entirely prohibited, while the import duty

Austria.

on other articles of commerce almost effectually prevented their admission. Hence it followed, that the price of many of the most common articles of clothing (as stated in the *British and Foreign Review*, vol. xi.), was higher from 75 to 100 per cent. than in London. This narrow commercial legislation, coupled with the inland toll, subsisting till 1849, between Hungary and the rest of the empire, could not but materially impede the free development of the commercial resources of the country. In no other department however has so great a progress been perceptible within the last 20 years as in commerce; for we find that in the decade between 1830 and 1840, the value of foreign commerce rose from 170 to 290 millions of florins; while in the year preceding the late war, it increased to upwards of 240 millions. This advance must undoubtedly be attributed in a large measure to the construction of different lines of railway; of which the chief are, the *Northern* or *Ferdinand's Line*, touching the Prussian frontier at Oderberg, and bringing Berlin within slightly more than a thirty hours' journey from the Austrian capital, the *Cracow-Silesian Line*, and the *South-Eastern Line*, running into Hungary. The most important line, however, by which it is contemplated to unite Vienna on the one hand with Galizia, and on the other with Trieste, and thereby with the Italian provinces, is as yet far from completion. In regard to foreign commerce, the seaport of Trieste occupies the foremost place, and owes its flourishing condition to the existence of the Lloyd Company, established in 1833, and three years after taken under government patronage. The steam vessels of this company are nearly forty in number; and, by means of their connection with the German railways, have already rivalled the London Oriental Company by opening up a communication with the East through Trieste. The value of the commerce of Trieste with foreign countries is, according to the latest statistics, 86 millions; that of Venice, 11 millions; and that of Fiume, 4 millions of florins.

In the year 1851, considerable alterations were effected in the Austrian tariff, the object of the government being to form a union with the German *Zollverein;* though it will be seen by a few examples that the duty on many articles of manufacture still amounts to a virtual prohibition. The import duty per cwt. on the following articles stand thus:—

	Florins.		Florins.
Raw coffee	10	Raw tobacco	10
Fine spices	25	Raw and spun silk	15
Tea	15	Cotton goods (according to quality), from	12 to 250
Refined sugar	14		

Woollen and silk manufactures are taxed in the same ratio as the foregoing.

The aggregate value of Austrian manufactures is, according to the last official return, estimated at 795 millions of florins. In this computation the following are the more important branches, and their respective value is thus stated:—

	Florins.
Stone and earthen ware	25,000,000
Glass and mirror manufacture	15,000,000
Hardware	49,000,000
Cotton	43,000,000
Flax and hemp	57,000,000
Silks	57,000,000
Woollens and cloth	63,000,000
Beer and spirits	44,000,000
Sugar	14,000,000

The harbours along the coast of Dalmatia are both numerous and commodious, but their trade must be inconsiderable until the country inland acquire population and wealth. In the northern part of the Austrian empire there are also great obstacles to foreign trade. Bohemia communicates with the sea only by the Elbe, and Galizia with still more difficulty by the Vistula; but these impediments are now almost removed by the establishment of railway communication in both these provinces.

Austria.

National Income and Finances.

In commercial countries, the public revenue arises principally from the excise and customs; but in a country chiefly agricultural, the case is very different. In Austria the limited extent of foreign trade renders the customs comparatively small; while the small number of towns, and their scanty population, lessen greatly the produce of the excise. An extra share of the public burdens must therefore fall on land, the assessment of which ought from time to time to be altered according to the amount of rents. In England, since the first imposition of the land-tax in 1692, there has been no renewed survey, or attempt to adapt it to the augmented rental; but in France and Austria the absolute insufficiency of other taxes rendered an increase of the land-tax indispensable. In Austria, the Emperor Joseph, among other changes, proposed a land and poll tax on a uniform plan, and attempted a general survey of the empire. Several years were devoted to this great work; but it encountered many obstacles, as well from the difference of value between the plain and mountain territory, as from the difficulty of computing rents in almost any province of the empire, the property of the peasantry obliging them to pay their landlords in produce or in labour instead of money. Since 1815 the Austrian government has endeavoured to correct defects in the existing assessment, but it is still in a very imperfect state. In 1819 a new regulation of the land-tax was established, which underwent material changes after the war of 1848. In the Hereditary States, as well as in Bohemia and Galizia, the land-tax was levied without distinction of class or rank; but in the aristocratic countries of Hungary and Transylvania the *noblesse* or gentry were exempt from it till 1848.

Public Revenue of Austria.

From the year 1831 to 1841 the average revenue of Austria was 133 millions of florins, which from 1841 down to the time of the last war amounted to an average of 170 millions. This increase, perceptible in the second decade, may be attributed chiefly to the introduction of the stamp-duty and other financial measures by Baron Kübeck; and it may be remarked that the increase of the indirect taxes by far exceeded that of the direct. From this revenue, which nearly covered the state-expenses, the military establishment alone absorbed in the year 1832, in consequence of the French revolution of 1830, as well as in the year 1846, during the troubles in Poland, more than 60 millions, and was never under 55 millions.

The public debt, which, as already observed, amounted, at the end of the war with Napoleon, to 500 millions of florins, was augmented to 800 millions, up till the date of the war of 1848. The interest alone of this debt amounted to 33 millions of florins. From this general view, the reader will understand the resources of Austria at the eve of a war which, while for two years it materially diminished her income, caused on the other hand a great addition to the public debt by reason of the vastly increased expenditure it occasioned. With the end of the war, the system of taxation and the rules in respect to states-revenue and expenditure in general, underwent fundamental alterations.

The injurious effect of the war upon the finances may be gathered from the following statement:—

	Income.	Expenditure.	Deficit in round numbers.
1848	121,819,625 flns.	186,679,486 flns.	65,000,000 flns.
1849	149,617,132 flns.	289,468,048 flns.	140,000,000 flns.

The year 1850 showed a considerable increase of income, which, including the direct and indirect taxes, rose to 195,000,000 florins, while the expenditure amounted to 250,000,000.

The income and expenditure of 1851 were as follow:—

Austria.

1. Direct Taxes.		2. Indirect Taxes.	
Land tax	58,684,661	Tax on consumable articles	25,055,640
House tax	7,371,944	Customs	19,918,315
Inheritance tax	130,063	Salt monopoly	28,677,167
Income tax on trades	3,925,860	Tobacco monopoly	13,532,458
Property tax	3,704,957	Stamps, and taxes on processes	15,758,968
Direct taxes of Cracow	156,771	Lottery	3,663,907
Other direct taxes	104,574	Post	132,829
		Turnpike tolls	2,291,271
		Other taxes	388,619
Total	74,078,830	Total	109,419,174

3. Income from State property..... 7,166,169

Total income, in round numbers, including the indemnification paid by Sardinia, 223,000,000 florins.

The total expenditure of this year amounted, in round numbers, to 278,000,000 florins. Deficit for 1851, 55,000,000 florins.

It may be observed that the year 1852, the financial statement for which has not yet been made public, promises a continued increase in the revenue; though the state of the provinces, as well as the general aspect of Europe, do not entitle us to calculate upon a reduction in the chief item of expenditure, viz. the army, which, in 1851, of itself absorbed more than 111,000,000 florins. The public debt amounted, in 1852, according to the estimate formed by the judicious and accurate Otto Hubner, in his *Jahrbuch fur Volkswirthschaftund Statistik*, to 1200 millions of florins, or at the rate of 32 florins per head.

It is thus seen that the revenue of Austria is surprisingly small if compared with England and France. This however is explained by the mere consideration of the manner in which human labour is employed. In manufacturing and commercial countries, such as England, agriculture is conducted with the benefit of capital and machinery; and the labour of 30 or 40 persons in 100 is sufficient to raise subsistence for the community at large. But in other countries of Europe the case is very different, the labour of half or of more than half the inhabitants being required to raise the needful subsistence. Thus in France, a great part of which is more backward than an untravelled Englishman can readily conceive, between 50 and 60 persons in 100 are and must be employed in country work, in consequence of the great inferiority of their agriculture, their farms being small, their ploughs and other implements miserably defective, their capital scanty, and machinery, such as threshing-mills, in a manner unknown. Hungary, Transylvania, and the southern frontier along the Danube, being still more backward than any part of France, more destitute of capital, and more deficient in machinery, the consequence is, that of the average population of the Austrian empire, the labour of not fewer than between 60 and 70 persons in 100 is needed for raising provisions; thus reducing to a comparatively small number the population of the towns, the persons disposable for trade and manufacture. This is at once apparent from a comparison of the town population in these different countries, which, as is evident, is by far the least in Austria. The largest towns in the latter besides Vienna, are Milan, Venice, Prague, and Pesth, each with a population above 100,000, which, taken together, does not much exceed the population of Paris alone, not to mention the immense population of London and other large towns in Britain.

Another very important point in estimating the resources of different countries is the degree of density in the population generally. In England, by the census of the year 1851, it was 4835 persons to a *German* square mile; in France, 3678; while in Austria it was only 3150, though its territory by far surpasses that of France. As to the comparative density of the town and agricultural populations, no satisfactory result has hitherto been obtained by the statistical writers; the prevailing opinion, however, is, that the population of the towns is in the proportion of 1 to 7 in comparison with the remainder. It is necessary, however, to bear in mind that the population of those towns which number less than 2000 inhabitants is generally classed among the agricultural. Now, it almost always happens that in a thickly-peopled district the wages are better and the consumption of taxed articles greater, per head, than in one that is thinly peopled; and hence the contribution to the public treasury is larger. Thus the inhabitants of Lombardy, Bohemia, and the Vienna district, pay considerably more per head than those of Hungary, Carinthia, or Upper Austria. Add to this, in the third place, that while England has all the benefit of an insular situation and liberal institutions, and France possesses an extensive line of coast, with considerable trade, the maritime provinces of Austria are both limited in extent, and but recently acquired; in short, the empire may be said to have as yet wanted almost entirely the stimulus to industry arising from communication by water, from a universally established steam-communication, and, above all, from a liberal commercial legislation.

Austria.

Military Establishment.

Austria has taken so prominent a part in the wars of the last and of the present age, that the nature and extent of her military means are subjects of great interest. The disposition of the inhabitants of Hungary, and of the more remote provinces of the empire, is well adapted to a military life. They are accustomed to pass their time out of doors, to indulge in active exercise, to follow the chase, and to occupy themselves with the care of horses. To such men marching and encamping are but a slight deviation from their established habits. The fire of the nightly watch is not more uncomfortable than that of their smoky cottages; whilst a loaf of bread, a slice of coarse pork, and a glass of spirits, are all the food and drink they desire. It is now more than a century since the Prussians began to take a lead in military discipline, the father of Frederick II. having carried both the manual and platoon exercise to a nicety unattempted by almost any other tactician. He left a highly disciplined army of nearly 80,000 men to his son, who, on the death of the Emperor Charles VI. in 1740, conceived that such a force would soon enable him to accomplish the conquest of Silesia. He lost no time in making preparations for war. The court of Vienna, alarmed, sent a special envoy to dissuade him from it; but Frederick was not to be deterred by any remonstrances, however urgent. The envoy adverting, on the one hand, to the careful training of the Prussians, and on the other to the recent practice of the Austrians in the field, declared to the king, "*Vos troupes, Sire, sont belles, mais les nôtres ont vu le loup.*" "*Vous convenez,*" replied the king, "*que mes troupes sont belles, je vous ferai convenir qu'elles sont bonnes.*" The words of the king were made good; the events of the war which ensued, as well as of the more arduous contest begun in 1756, having proved, on many trying occasions, the great advantage of a high state of discipline. This led the Austrian generals and war ministers to follow the example of the Prussians, as well by carefully training their infantry, as by new-modelling the "free corps" of horsemen, Croats, Sclavonians, and Hungarians, who had hitherto been left to their national mode of fighting. By dint of perseverance, Marshal Lascy and other military men in Austria succeeded at last in bringing these half-civilized combatants under the discipline of regular cavalry.

The French, in the wars of the revolution, were remarkable for celerity of movement in collective bodies, but bestowed comparatively little attention on the *minutiæ* of discipline. The Austrians were charged with following a con-

Austria.

trary system; with too much care as to details, and too little as to general movements. Their lines are said to have suffered on various occasions, in particular in the dreadful conflicts at Essling and Wagram, from continued exposure to the field-pieces of the enemy; and their infantry was said to be slow in executing most movements except those from front to rear.

In former times the Austrian government, conscious of the deficient education of its subjects, gave important commands to Italian officers, amongst whom the most remarkable were Montecuculi and Prince Eugene. At present there are military schools at Vienna and several of the provincial towns. Up to the year 1848 the Austrian army, though by far inferior in general instruction to those of Prussia and France, was, in a strictly military point of view, and in discipline, held equal to any in Europe. Its prestige was, however, entirely lost during the war of 1848, when a large part of the army, and especially the Hungarians, deserted from the imperial standard to rally round their national colours; a circumstance which led to the complete military demoralization of the whole army. At the conclusion of the war, many of the revolutionary troops were forcibly enrolled into the imperial ranks, a policy which can only serve to infect the whole military force with new ideas, and an anti-dynastic spirit.

The whole army, including the *landwehr*, is computed at 500,000 men, and consists of 63 infantry regiments of the line, 20 grenadier battalions, 14 frontier regiments, and 24 rifle battalions; the cavalry consists of eight regiments of cuirassiers, 7 of dragoons, 12 of hussars, and 11 of lancers, besides the different corps of artillery, and the sappers and miners.[1]

In most of the provinces of the Austrian empire the levies were at first made for militia service (*landwehr*), and the regular regiments were kept up by successive draughts from that force; while in Hungary the diet voted the respective contingents. Since the end of the last war, however, one uniform system of arbitrary recruiting has prevailed throughout the whole empire.

The horses for the Austrian light cavalry are drawn from Hungary and Galizia; those for the heavy cavalry chiefly from Bohemia and Moravia. Clothing, arms, ammunition, and harness, are all furnished at different stations, in Bohemia, Moravia, and the Hereditary States. The duration of military service in Austria was long unlimited; but in the early part of the present century it was reduced, as in this country, to specific periods. For invalids and veteran soldiers there is a provision similar to what is made for our military; they are either received into hospitals or allowed small out-pensions. For further details connected with the Austrian military establishment, see ARMY.

Magnitude of the resources of Austria.

The limited revenue of Austria, and her equally limited credit in a financial sense, prevent her from making a great military exertion at short notice. She cannot, unless when aided by foreign subsidies, equip for offensive operations, or send to a distance, armies of any very considerable force. Hence her power in attack is restricted so as to form a remarkable contrast to the extent of her means for continuing a contest by filling up the blanks in her regiments, year after year, by fresh levies. In her long and arduous struggle with France, the losses of each campaign appeared to be supplied without making a serious impression on her numbers, or distressing her productive industry. The causes of this are obvious. A country like England, possessing monied capital, can at short notice embody an army, and send it to a distance, amply equipped and provided; whilst an agricultural nation like Austria is limited in its extent of exertion at the moment, but, from the amount of its population, almost indefinite in its resources. The long duration of several of her wars is to be ascribed to two causes; her inability, on the one hand, to overpower her opponents by a great effort; and her power on the other, to keep up a certain degree of exertion for a long period. It was thus that Austria carried on the religious war in Germany during thirty years, and persisted in the war with France in 1713, after England and Holland had withdrawn. Maria Theresa would have done the same towards Prussia in 1763, had she not been forsaken by her allies; whilst, in the wars with revolutionary France and Buonaparte, we have seen Austria, worsted in five successive contests, return as often to the charge. At present, however, the whole condition of Austria, in regard to her resources, has been altered in consequence of the late internal revolutions, and the unceasingly disaffected condition of the various nationalities, many of which only await the embroilment of Austria in a foreign war in order to free themselves for ever from her dominancy.

Austria.

Ships of war.

The Austrian navy is as yet merely in an incipient state, and is only entitled to notice because the possession of Venice, Trieste, and the fine harbours along the coast of Dalmatia, gives great facility for the creation of a maritime power. At present it consists of 4 frigates, 6 corvettes, 11 brigs, and 6 schooners; in all 27 sailing vessels; besides 10 steamers, the largest of which does not exceed 300-horse power.

Religion, Education, National Character.

Religion.

The population of the Austrian empire, classed according to their respective creeds, will stand thus:—

Catholics	26,357,172	Calvinists	2,161,765
Greek Church	3,694,896	Unitarians	50,541
Non-united Greeks	3,118,605	Jews	729,005
Lutherans	1,286,799	Other religions	2,350

Austria, as is known, was the hereditary foe of Protestantism in the seventeenth century, cruelly persecuting the population of Bohemia, the country of the unfortunate John Huss and Jerome of Prague. In Hungary the struggle of the Protestants against the Hapsburgs continued into the eighteenth century; nor have they ever been permitted the enjoyment of the liberties so often stipulated to them. In more recent times no actual persecutions have taken place, but the Catholic faith has always remained the predominant and privileged religion of the empire. The north and west of Germany frequently exhibit Catholic and Protestant communities in the same vicinity; and nowhere are the superior industry and intelligence of the latter more strongly marked. The traveller who passes from Saxony into Bohemia cannot fail to regret that the Reformation should not have made its way into the Austrian dominions; the result would doubtless have been a very decided advancement in science and productive industry. Literature, manufactures, trade, would then have been cultivated in the south and east of Germany with the same zeal, and probably with the same success, as have marked their progress in the south and west.

In Austria, as in France, the Catholic clergy are generally educated in humbler seminaries than universities. Oratory forms no part of their studies, and would, in fact, be misplaced before a German congregation, which meets for the purpose of fulfilling, soberly and tranquilly, a religious duty. Sermons, therefore, are, in almost all parts of the Austrian dominions, little more than plain moral lessons, deduced from the sacred writings; and the reputation of a clergyman, particularly in country parts, rests chiefly on his attention to the sick, and the performance of private and unostentatious duties. The sovereigns of Austria have in general resisted the pretensions of the popes; reserving to themselves several important rights, such as the imposing of taxes on church property, the nomination of bishops and

[1] The variation between some of the numbers in this estimate and in the article ARMY, will be understood by reference to the fact that the strength of the Austrian military establishment fluctuates with the chances of peace or war.

Austria. archbishops, and the option of restricting or even preventing the circulation of papal bulls. After the late war, however, the Austrian emperor surrendered his right in spiritual affairs to the pope.

The extent of landed property in Austria belonging to the Catholic Church is very considerable, as may be inferred from the number of abbeys and convents. Though a good deal reduced within the last half-century, there are still nearly 300 abbeys and above 500 convents in the empire. The head of the Austrian church is the archbishop of Vienna; but the bishop of St Polten appoints the regimental chaplains, and is the superior of all clergymen doing duty with the army.

National education. A deficiency in national education has long been a subject of reproach to the Austrians; and their apathy in regard to literature and politics may undoubtedly be ascribed to the strict censorship, tending to stifle all liberal and useful inquiry. Always surrounded by the police and by secret spies, the Austrians, and especially the Viennese, have at last naturally become totally disused to anything like serious conversation in public, and appear seemingly satisfied to make up for this deficiency in the enjoyment of the other pleasures offered by life. The desire of acquiring property is of course as strong, or nearly as strong, in this as in other countries; but the inhabitants have still to acquire that intellectual activity which stimulates so largely to exertion in England and France, and, above all, in the Protestant part of Germany; a consummation, however, not to be brought about under absolute rule. Saxony is the centre of literature for that country; and the society which is within the reach of a youth at the university of Vienna is not to be compared to that of Dresden or Leipsic. The Austrian dialect of Germany is unpleasant, having a slowness of accent and a hissing tone, particularly in the mouths of the lower orders. Hence French is the language used, not only at court, and by diplomatists, but by genteel society generally. The universities in the Austrian empire are as follow:—Vienna, Prague in Bohemia, Pesth in Hungary, Lemberg in Galizia, Innspruck in Tyrol, Grätz in Styria, Olmütz in Moravia, and Padua and Pavia in Lombardy; in all, 9 universities, attended by more than 12,000 students. There are besides 43 academies, 33 lyceums or high schools, and 266 gymnasia or Latin schools. Of military schools there are in all 10 in the empire; the two principal in Vienna, the others in provincial towns. The primary or elementary schools throughout the empire correspond in some measure to the parish schools in Scotland. They were greatly increased half a century ago in the reign of Joseph II., and in the Austrian provinces they appear to be adequate to the wants of the population; but in Hungary and the remote parts of the empire there are still great deficiencies in the provision even for this, the first stage of education. The university of Vienna dates from the middle of the thirteenth century, the time when the residence of the court, being fixed in that city, began to give importance to it, and to call for improvements in public education. It was long under the management of the clergy, who, in the middle ages, were the only men of letters; but a century ago Van Swieten, the celebrated physician, induced the government to take it into their own hands, and to give a great extension to the medical department; Vienna, from the number of its inhabitants and the extent of its hospitals, being much fitter for a medical school than any other city in Germany. The consequences of Van Swieten's representations were the fitting-up of a botanical garden, an anatomical theatre, a military hospital, and, at a subsequent date, a veterinary school. The university of Vienna is now at the head of the medical schools in Germany. It contains also public classes for law, theology, classics, philosophy, and general literature, in most of which the reputation of the professors is respectable, though not greater than in other universities, such as Göttingen, Leipsic, and Halle. The number of students at the Vienna university in 1848 was 3215. Vienna contains also an academy for the fine arts, a seminary for the Eastern languages, and facilities for the study of modern Greek. Among the military institutions are a school for cadets, and of late years a polytechnic school for engineers. This capital has also several normal seminaries for training teachers for provincial towns and villages. The imperial library at Vienna is very extensive, as is the collection of medals and coins. The university of Prague is of old date, and well attended by Bohemians, but it does not rank high in the scale of German seminaries. Pesth, Lemberg, Grätz, and the other universities, are of importance only to the population of their respective towns, and their vicinity. Austria.

In travelling for instruction, the Austrians, like the French, are far behind our countrymen, in consequence partly of the want of pecuniary means, partly of their unambitious and uninquiring character. Individuals, however, may be cited among the Austrians, who, like Baron Humboldt among the Prussians, have traversed remote regions in quest of information; but their number is small when compared with the extent and population of the empire. Still Austria can boast of several names of eminence in literature, though the greater part of its distinguished writers, and in particular the poets, have always thought it safer to exchange Vienna for some town of Germany. The most eminent poets of whom the Austrian capital can boast are, Anastasius Greun, and the well-known humourist M. G. Saphir. Hammer, the founder of the Oriental Society at Vienna, has long been known for his acquaintance with Persian literature; while there are many able writers on natural philosophy and geography, connected with the various *Academies of Science* in the empire.

In painting and sculpture, as in architecture, the Austrians have as yet made no great figure; but the case is very different in regard to music. Haydn and Mozart were both formed at Vienna; and it has been said with truth, that a foreigner can hardly receive a higher gratification than by being present at the oratorio at Vienna in commemoration of Haydn. If in vocal music the Germans are inferior to the Italians, they fully maintain the competition in instrumental performance. In short, the passion for music exists here in the humblest ranks, and under circumstances apparently the least favourable to it. This is equally the case in the populous districts adjoining the Danube, and in the secluded spots of Tyrol and Carniola.

National character Statistical writers class the population of the Austrian empire according to national descent, thus,—

Of Sclavonian origin, including the Poles, Croats, and Serbs	15,282,248
Of German	7,917,195
Of Magyar	5,418,773
Of Italian	5,042,225
Of Wallachian	2,640,492

Besides Jews, Armenians, and Gypsies, forming a comparatively small number.

The Sclavonians (called in Latin *Slavi* or *Sclavi*, and in their own language *Slowacs*) inhabited, in remote ages, a part of the vast tract of country known to the ancients by the name of Scythia. Their descendants are widely spread; for their language and habits are to be traced in the Illyrian provinces, in Hungary, Poland, the east of Germany, and even in the western frontier of Russia. Upon the whole, they form the most uncivilized portion of the population of the empire—a circumstance to be partly accounted for by the comparatively small number of their nobility, these having been in the course of time absorbed into the German or Magyar populations. The Wallachians are almost equally backward; but the Magyars are a spirited race, averse to sedentary work, accustomed to exercise in the open air, and

Austria.

prompt in obeying a summons to military duty, and, above all, ever ready to join their nobles in the defence of the country.

In Styria, Carinthia, and other mountainous tracts, the manners of the inhabitants are very primitive. Content with the produce furnished by their lands and cattle, and as cheerful and frank as moderate desires can make them, they seem to have no wish beyond the limits of their native districts. They are, it must be allowed, very ignorant and superstitious; being still blindly attached to traditionary usages, and among others, to that of making pilgrimages to a distance as the best means of obtaining forgiveness for trespasses.

The character of the Germans in the Austrian dominions is in general praiseworthy. Sincerity, industry, and habits of order, are all conspicuous in them; and the number of criminal offences committed among them is remarkably small. In many extensive districts, year after year passes without a necessity for capital punishment. The French soldiers, who, in marching through Austria, were very often lodged in detached cottages, and at the mercy of the inhabitants, bore a favourable testimony to their humanity; and there scarcely occurred, either there or elsewhere in Germany, any example of those secret assassinations which were unfortunately so prevalent in Spain.

The habits of the females in Austria, in the large as in the small towns, are very domestic. Without taking so active a part as French women in either business or conversation, they claim regard for a steady fulfilment of the duties of wives and mothers. The lower orders have similar habits; and a traveller may visit village after village without hearing of a single instance of domestic disquietude. The care of children, the performance of their daily tasks, and punctual attendance on divine worship, seem to occupy all their thoughts.

A striking feature in the national character of the Austrians is a continued equanimity, a general good humour and forbearance, as if they had little or no cause for complaint in regard either to individual circumstances or public affairs—a circumstance which rendered the more remarkable the impetuous movement of 1848. This general equanimity and aversion to change produces as its natural consequence a blind adherence to old usages, and a disinclination to almost every kind of innovation. Hence their stationary condition, their backward agriculture, their slowly improving manufactures, and their extravagant deference to hereditary rank—a deference often dearly paid for in war, when men of inferior talents have been intrusted with important commands. On the whole, it must be admitted, that no country in Europe stands more in need than Austria of the benefits arising from the diffusion of knowledge—a remark which applies to the upper as well as to the lower classes.

We should, however, err greatly were we to suppose the apparent slowness of the Austrians indicative of deficiency of invention. On the contrary, their tranquil and sedate habits are more favourable to original combinations than the sprightliness of the French. But in Austria, as in other parts of Germany, mechanical ingenuity is often applied rather to make a display of skill, or to gratify a fancy, than to accomplish a useful purpose. In one part of a journey through that country a traveller finds a machine so framed that, with a slight impulse, it performs the functions of a chess-player; in another part he sees a head which may be made to imitate the human voice; and in a third place, an instrument uniting the most varied sounds of music. In machinery, as in politics, the speculations of the Germans often bear evidence of considerable ingenuity, but at the same time of the absence of practice and experience.

Connection with the Germanic body.

The Germanic confederation bore, as is well known, during many centuries, the name and form of an empire, consisting of a number of separate states, of which Austria was by far the greatest. Her dominions in Germany comprised Bohemia, Moravia, and Silesia, in addition to the circle of Austria, which contained Austria Proper, Styria, Carinthia, and Carniola; hence the successive election, during nearly four centuries, of the head of the house of Austria to the rank of the Emperor of Germany. This dignity being renounced by Francis II. in 1806, the connection of Austria with the rest of Germany on the previous footing was dissolved: nor was it renewed in the final adjustments of 1815, by which the Germanic body was declared a confederation, but not an empire; for it has no longer an acknowledged head, questions affecting the confederation at large being discussed in the diet or assembly of deputies from the different states, and determined by a majority of votes. Each confederate state is pledged to supply, when required by the diet, a military force proportioned to its population. Austria having in Germany a population of twelve millions, her quota in time of war is nearly 100,000 men; that of Prussia is 80,000. It has been seen how Austria desired to enter, with all her provinces, into the German confederacy, and how this scheme failed, in consequence of the remonstrances of the other powers of Europe.

Austria.

Since the abrogation of the imperial form in Germany, the "Circle of Austria" is no longer an official designation; but the name of "Hereditary States," so often used, has reference to the same provinces, viz., Austria Proper, Styria, Carinthia, and Carniola, which during five centuries and upwards have belonged to the house of Hapsburg by hereditary descent. At present, however, all the provinces are governed by the same central jurisdiction and the same organic laws. In these the authority of the emperor is almost uncontrolled. He is the head not only of the executive power, but of the church, and virtually of the legislature.

The Hereditary States.

The judicial body in Austria is far more numerous than in this country, the difficulty in travelling requiring that there should be courts of justice in a great number of provincial towns. Their scale of remuneration, however, is much below ours, being so small as to disincline even the most eminent pleaders from relinquishing their practice. The administration of justice in Austria long took place, as in this country, by reference to ancient usage, and to a multitude of decisions, without much system or consideration of general principles. The perplexity attendant on this vague and undefined course being doubly felt in a country where individuals were in general ignorant, and the press inefficient, the government became aware, so long ago as the middle of last century, of the necessity of publishing the laws in a collective form. Accordingly, in the year 1767, a code was published in eight folio volumes. This was a first step towards improvement; but the work, from its bulk and its deficient arrangement, proving of little use, instructions were given by the government to an eminent civilian named Von Horten, to recast it in a condensed and improved form. This was necessarily a work of great time and labour, and it was not till 1794 that the first part of the civil code came forth in an improved shape. The remainder followed in a few years, when printed copies were distributed in all directions, and local commissions appointed to report on its applicability to the usages of the different provinces of the empire. At last, in 1812, the civil code was definitively promulgated, and applied to practice. With the criminal code a similar course had been adopted somewhat earlier; it had been promulgated in 1803, and introduced into practice the year after. Most of all these, however, were swept away by edicts issued since 1849.

Law.

Of the radical changes the Austrian empire has undergone in consequence of the war of 1848, the following are the most important:—Formerly, the different provinces of the empire were more or less governed by laws proper to

Austria ‖ Automaton.

themselves, being, however, with the exception of Hungary, dependent on the central Board of Vienna in regard to their general administration; but since the new state of affairs, all the provinces, without exception, are ruled by uniform laws, promulgated by the emperor, and all are alike under the immediate jurisdiction of the ministry at Vienna. The governors and district-commissaries of the various parts of the empire are the direct nominees of the emperor, who, in a manifesto dated December 31. 1851, abrogated the *octroyed* constitution of March 4. 1849, declaring also the nullity of the responsibility of ministers, whom he decreed to be responsible to himself alone. Thus did the emperor formally belie his repeated and solemn assurances of transforming Austria into a constitutional monarchy, and the value of the equally solemn assurances in regard to the equalization of the different nationalities of the empire, appears to have amounted up to the present time (1853) to nothing more than that all should alike be subjected to the arbitrary regulations of the emperor and to martial law.

To all that has been said we must only add, in conclusion, that, up to the year 1848, Austria in her foreign policy followed an entirely independent course, acting frequently in concert with England, and, upon the whole, in amicable relations with the Ottoman Porte; while a certain coolness subsisted between her and France from the time of the accession of Louis Philippe. Now, however, the belief prevalent in the Austrian cabinet that the foreign policy of Britain encouraged the late popular movements in Italy and Hungary, has led to an alienation of feeling, undiminished to the present day; and a like feeling has been created towards Turkey, from the refusal of the latter to give up the Hungarian refugees who took shelter in her dominions at the end of 1849. Austria, therefore, is now more than ever influenced by the counsels of the cabinet of St Petersburg, and the more so, in consequence of the armed assistance so readily afforded by the Czar in the crisis of 1849. It would be out of place here to speculate on the probable future of Austria. It may, however, be safely asserted, that the unabated and abiding discontent in the Italian provinces and Hungary, which, now four years after the restoration of peace, are only kept down by force of arms; as well as the disaffected condition of the Sclavonic population, with whom Austria, after having in part used them as an instrument for her own purposes, has never fulfilled the promises she had held out,—cannot inspire much hope of a consolidation of the empire, or afford a reasonable guarantee of any lengthened internal tranquillity. (J. L—E.) (E. S—D.)

Austria ‖ Autonomy

AUTOCHTHONES (*αὐτὸς, self,* and *χθὼν, earth*), an appellation assumed by some nations, importing that they sprung, or were produced, from the same soil which they inhabited. In this sense *Autochthones* is nearly synonymous with *Aborigines*. The Athenians valued themselves on their being Autochthones, *self-born* or *γηγενεῖς, earth-born;* it being the prevailing opinion among the ancients, that, in the beginning, the earth, by some prolific power, produced men, as it still does plants. The proper Autochthones were those primitive men who had no other parent than the earth; but the name was also assumed by the descendants of these men, provided they never changed their ancient abode, nor suffered other nations to mix with them. In this sense it was that the Greeks, and especially the Athenians, pretended to be Autochthones, and, as a badge of this distinction, wore in their hair a golden grasshopper, an insect supposed to have the same origin.

AUTOCRAT, a person vested with an absolute independent power, by which he is rendered unaccountable to any other for his actions. The power of the Athenian generals or commanders was usually limited; so that, at the expiration of their office, they were liable to render an account of their administration. But, on some extraordinary occasions, they were exempted from this restraint, and sent with a full and uncontrollable authority; in which sense they were styled Αὐτοκράτορες. The same people also applied the name to some of their ambassadors, who were vested with a full power of determining matters according to their own discretion. These were denominated Πρεσβεῖς Αὐτοκράτορες, and resembled our plenipotentiaries.

AUTO DA FE. See ACT OF FAITH.

AUTOGRAPH denotes a person's own handwriting, or the original manuscript of any book, &c.

AUTOLYCUS, a famous robber who lived on Mount Parnassus, and was said to be the maternal grandfather of Ulysses.

AUTOLYCUS, of Pitane in Æolis, the author of two astronomical treatises, which are the most ancient specimens of Greek mathematics extant. They are edited by Dasypodius in his *Sphericæ Doctrinæ Propositiones*, Argent. 1572. He probably lived about B.C. 350. See Delambre's *Hist. de l'Astronomie Ancienne.*

AUTOMATON (from *αὐτός, self,* and *μάω. I move*), a self-moving machine, or one so constructed, by means of weights, levers, pulleys, and other mechanism, as to move for a considerable time as if endowed with animal life. According to this description, clocks, watches, and all machines of that kind, are automata.

Under the article ANDROIDES, it was observed that the highest perfection to which automata could be carried was to imitate exactly the motions and actions of living creatures, especially of mankind, which are with more difficulty imitated than those of other animals. Very surprising imitations, however, have been made of other creatures. So long ago as 400 years before Christ, Archytas of Tarentum is said to have made a wooden pigeon that could fly; nor will this appear at all incredible, when we consider the flute-player made by M. Vaucanson, of which an account is given under ANDROIDES. Dr Hooke is also said to have made the model of a flying chariot, capable of supporting itself in the air. But Vaucanson distinguished himself still more, by making a duck, which was capable of eating, drinking, and imitating exactly the natural voice of that fowl. What was yet more surprising, the food it swallowed was evacuated in a digested state; that is to say, considerably altered from what it was when swallowed; and this digestion was performed on the principle of solution, not of trituration. The wings, viscera, and bones, of this artificial duck, were also formed so as to resemble those of a living animal. Even in the actions of eating and drinking this resemblance was preserved; the artificial duck swallowed with avidity and with quick motions of the head and throat, and likewise muddled the water with its bill, exactly like the natural bird. Perhaps not the least ingenious of real automata was that which was exhibited within the last few years at Edinburgh and elsewhere, which enunciated several simple sentences with surprising distinctness. See also ANDROIDES.

AUTONOMY (*αὐτός,* and *νόμος,* a law), a power of living or being governed by our own laws and magistrates. The liberty of the cities under the faith and protection of the Romans consisted in their autonomia; that is, they were allowed to make their own laws, and elect their own magistrates, by whom justice was to be administered, and not by Roman prefects or judges, as was done in other places which were not indulged with the autonomia.

AUTONOMY, a term in the philosophy of Kant, by which

Autumn || Auxerre.

he designates the absolute sovereignty of reason in the sphere of morals. On this *self-legislative* quality of reason is founded, according to him, the true nature and the sole proof of man's *liberty*.

AUTUMN, the third season of the year, when the harvest and fruits are gathered in. Autumn is represented in painting by a man at perfect age, clothed like the spring, and likewise girded with a starry girdle, holding in one hand a pair of scales equally poised, with a globe in each, and in the other a bunch of divers fruits and grapes. His age denotes the perfection of this season; and the balance that sign of the zodiac which the sun enters when our autumn begins.

Autumn begins on the day when the sun's meridian distance from the zenith, being on the decrease, is a mean between the greatest and the least, which in our hemisphere is supposed to happen when the sun enters Libra. Its end coincides with the beginning of winter. Several nations computed the years by autumns; the Anglo-Saxons, by winters. Tacitus tells us that the ancient Germans were acquainted with all the other seasons of the year, but had no notion of autumn. Lidyat observes of the beginning of the several seasons of the year, that

> Dat Clemens hyemem, dat Petrus ver cathedratus,
> Æstuat Urbanus, autumnat Bartholomæus.

Autumn has been reputed an unhealthy season. Tertullian calls it *tentator valetudinum*; and the satirist speaks of it in the same light: *Autumnus Libitinæ questus acerbæ.*

AUTUMNAL EQUINOX, that time when the sun enters the autumnal point. This happens about the 22d or 23d of September.

AUTUMNAL POINT is that part of the equinox from which the sun begins to descend towards the south pole.

AUTUMNAL SIGNS, in *Astronomy*, are the signs Libra, Scorpio, and Sagittarius, through which the sun passes during the autumn.

AUTUN, the capital of an arrondissement of the same name in the department of Saône and Loire, in France, is picturesquely situated on the declivity of a hill, at the foot of which flows the Arroux. This is one of the most ancient towns of France, and when Cæsar invaded Gaul it was by far the greatest and wealthiest town of the Ædui. Its name was then Bibracte, but being afterwards much improved and embellished by Augustus it took that of Augustodunum. Many Roman and other remains still attest its former greatness; among which are large masses of its ancient walls, and two gates in admirable preservation. The cathedral is a structure of the eleventh century, and contains an elegant fountain in its square. Autun is the seat of a bishopric, and has a college, a diocesan seminary, a museum, library, theatre, &c., with tribunals of primary jurisdiction and commerce. It has manufactures of cotton goods, hosiery, leather, and paper, with a considerable trade in timber, hemp, and cattle. Population (1851), 11,094. The arrondissement is divided into 8 cantons and 85 communes. Population in 1851, 100,286.

AUVERGNE, an ancient province of central France, now in the departments of Puy de Dome and Cantal. See FRANCE.

AUVERNAS, a very deep-coloured heady wine, made of black raisins so called, which are produced near Orleans. If kept two or three years it becomes excellent.

AUXERRE, an arrondissement in the department of the Yonne, in France. Its extent is 773 square miles, or 494,905 acres, divided into 12 cantons and 131 communes, with 121,539 inhabitants. The capital, of the same name, is situated on the banks of the Yonne, in a district productive of wine; and is built in an antique fashion, with an ancient cathedral and a splendid palace. It has several normal schools, a society of agriculture, botanic garden, museum, theatre, &c. The Yonne is navigable from a little above the town. Pop. in 1851, 12,673. Besides trade in wine and in fire-wood, there are manufactures of cloths, druggets, serges cotton and woollen stockings, and some considerable tanneries. Long. 3. 34. 21. E. Lat. 47. 47. 57. N.

Auxesia || Ava.

AUXESIA, in *Mythology*, the name under which Persephone or Proserpina was honoured at Troezen and Epidaurus, as presiding over the nourishment and increase of the crops.

AUXESIS (αὔξησις), in *Rhetoric*, a figure whereby anything is magnified too much.

AUXILIARY, whatever is aiding or helping to another.

AUXILIARY VERBS, in *Grammar*, are such as help to form or conjugate others, as *to have, to be.* See GRAMMAR.

AUXONNE, a city in the arrondissement of Dijon and department of Côte d'Or, in France. It is on the Saône, and is strongly fortified. Pop. 5800. Besides their manufactures of cloth and serges, the inhabitants carry on by the river considerable traffic with Lyons. Long. 5. 24. E. Lat. 47. 13. N.

AVA, the capital of the Burman empire. It is situated on the Irawaddy, which is here 3282 feet broad, and which, making a bend out of its ordinary course, flows past the city on the N. On the E. it has the river Myit-nge, a rapid stream 450 feet broad, which flows into the Irawaddy close under its walls. From this river a canal has been dug, through which its waters flow on the S.E. angle of the city, and are again brought into the same river. On the S. flows the deep and rapid torrent of the Myit-tha, an offset of the Myit-nge, which, falling into the Irawaddy, forms the defence both of the S. and W. faces of the town. This place is divided into the upper and lower, or the lesser and the larger town, both of which are fortified. The brick wall that surrounds the city is 15½ feet in height, and 10 feet in thickness, on the inside of which is thrown up a bank of earth forming an angle of 45 degrees. There is a ditch round the outer wall which is inconsiderable, and in the dry season fordable in every part. The lesser town is chiefly occupied by the royal palace, the hall of justice, the council chamber, the arsenal, and the habitations of a few courtiers of distinction. A strong well-built wall of more solid construction than the outer wall of the city, and about 20 feet high, incloses the square in which these buildings are situated, and on the outside is a teak-wood stockade of the same height. The ditch which surrounds the lesser town is moreover deeper and broader than that of the city, and when full is not to be forded. There are, however, three causeways across, which communicate with the adjacent country. The circumference of the city, excluding the suburbs, is about 5½ miles, but over this extensive area the houses are but thinly scattered; some quarters are indeed wholly destitute of habitations, and have the appearance merely of neglected commons. In general the dwellings of the inhabitants are of the most miserable sort, being mere huts thatched with grass. Wretched, however, as are such habitations to European eyes, the poorer classes are perhaps better lodged than in other parts of Asia. Their sleeping places are elevated two or three feet from the ground, which is a convenience not enjoyed by the masses in Bengal. Some of the houses of the chiefs are constructed of planks, and tiled; but there are not, according to Mr Crawford, more than half a dozen houses built of brick and mortar. Ava, like all the other Burmese towns, is adorned with numerous temples, of which the gilded spires rising aloft present on a distant view of the place a splendid and imposing appearance, which is far from being realized on a nearer inspection. The largest of these temples contains two distinct edifices, one in the ancient, the other in the modern form; the former containing an image of Guatama, not of marble as Symes supposes, but of sandstone. It is in a sitting posture, and is 24 feet in height. The head is 8 feet in diameter. There is another very large temple, and a third called the "Beautiful." The one called Maong-Ratna is of great celebrity; it is the one in which the public officers of

Avadoutas ‖ Avallon.

the government take, with the most solemn forms, the oath of allegiance. The temple called Maha-mrat-muni had an addition made to it some years ago, of which Mr Crawfurd mentions that the numerous and richly-gilded pillars and splendid ceiling exceeded anything that was to be seen without the palace. Ava contains eleven markets or bazaars, composed of thatched huts and sheds, which, however, are well supplied with all that is necessary for the wants of the people. Besides native commodities, there are exposed in these markets the produce of China and of Lao, with British cottons, woollens, glass, and earthenware. The Burman monasteries are mostly built of wood; and of those composed of more solid materials, a few ancient ones are nearly all that are to be seen. The only exception is a monastery built some years ago by the queen, adjoining the palace, an unshapely fabric of immense size, but a very conspicuous object.

The capital of the Burman dominions, according to the political divisions of the empire, comprehends the town of Sagaing on the opposite shore of the Irawaddy, and the town of Ummerapoora or Amarapura, four miles to the E. The town of Sagaing extends along the Irawaddy for more than a mile and a half, but is of inconsiderable breadth. It consists of mean houses thinly scattered among gardens and orchards; the principal trees in the latter consisting of fine old tamarinds. Over the site of the town and its environs are scattered innumerable temples, some of them old and ruinous, others modern. On the river face it has a brick wall about 10 feet in height, with parapet and embrazures like that of Ava, and extending for above half a mile along the river. Ummerapoora is a large place, and was formerly the capital; but Ava, which was twice before the capital, was again made so in 1822. To each of the towns of Ava, Sagaing, and Ummerapoora, are attached districts, the two former of which extend 12 miles along the river, and are of equal breadth. The district of Ummerapoora is of equal size, so that Ava must be considered as not only the name of the capital, but of a large district around, which includes an area of 288 miles, containing, according to the most accurate estimate, 354,200 inhabitants. But the city of Ava is not supposed to contain more than 50,000 inhabitants; and according to Mr Crawfurd, half that number would be nearer the truth. The place, taken altogether, affords few or no indications of industry or commercial enterprize. Lat. 21. 52. Long. 96. 1.

The entire territory subject to the Burmese sovereign is sometimes called Ava, the custom of applying to a country or province the name of its chief place being common in the East. It appears, however, preferable, where a distinct name for a country exists, to class the general information relating to that country under such name. The reader, therefore, is referred in this instance for such information to the article BURMAH. (D. B—N.) (E. T.)

AVADOUTAS, a sect of Indian Brahmins, who in austerity surpass all the rest, covering their nakedness with a piece of cloth only, some of them even dispensing with that, and besmearing their bodies with cow-dung. When hungry some enter into houses, and, without speaking, hold out their hands, eating on the spot whatever is given them. Others retire to the sides of holy rivers, and there expect the peasants to bring them provisions, which they generally do very liberally. See HINDUSTAN.

AVAL. See BAHREIN.

AVALANCHE, the name given to a prodigious mass of consolidated snow, which, disengaged from the summits of more elevated peaks, frequently rolls down the sides of the Alps. See ALPS.

AVALLON, an arrondissement in the department of the Yonne, in France, comprehending five cantons and seventy communes. Area, 244,480 acres; pop. 47,524. The capital, of the same name, is a handsome town, finely situated on a granite rock, at the foot of which flows the river Voisin. It has some manufactures of cloth, hats, hosiery, leather, and paper, and a considerable traffic in fire-wood, which is conveyed by the Voisin, the Yonne, and the Seine, to Paris. Pop. in 1851, 5740. Long. 3. 56. E. Lat. 47. 30. N.

Avatar ‖ Avenbrugger.

AVATAR, a Sanscrit word signifying *a descending*, applied in Indian mythology to incarnations of Vishnu, and of some of the inferior deities. See HINDUSTAN.

AVATCHA, a bay on the S.E. coast of Kamtschatka, the best on that coast; Lat. 52. 52. N. Long. 158. 47. E. On this bay is situated a small town of the same name; and about 20 miles inland is the volcano of Avatcha, rising to the height of 9055 feet.

AVEBURY, a village of England, in the county of Wilts, 6 miles W. of Marlborough. It occupies the site of a curious ancient structure, supposed to be Druidical. This consisted of a large outer circle formed of 100 stones of from 15 to 17 feet in height, and about 40 feet in circumference, inclosing an area of about 1400 feet in diameter. This circle was surrounded by a broad ditch and lofty rampart. Within its area were two smaller circles, each consisting of a double concentric row of stones; a stone pillar 20 feet high occupying the centre of the one, and a cromlech that of the other. Two avenues of approach, consisting of double rows of stones, branched off from this structure to other circles about a mile distant towards the S. and W. Few traces of this immense structure now remain,—the stones having been broken down and used in the construction of the houses of the village, and for other purposes. In the vicinity are a number of cromlechs and barrows: among the latter is Silbury Hill, said to be the largest barrow in Europe. It is about 2000 feet in circumference at the base, rising in a conical form to the height of 170 feet—the diameter of the summit being 120 feet.

AVEIRO, a town of Portugal, province of Beira, the seat of a bishopric and college. It has a thriving trade in oil, salt, fish, wine, and oranges. Pop. 4500. Long. 8. 34. W. Lat. 40. 40. N.

AVEIRON. See AVEYRON.

AVELLA, a town of Naples, in the province of Terra di Lavoro, in a fine situation, and commanding most extensive prospects. It is distant about 20 miles from Naples, and contains 6000 inhabitants. Near it are the remains of the ancient Abella. See ABELLA.

AVELLINO, the ancient *Abellinum*, a fortified city of Naples, in the province of Principato Ultra, at the foot of Mount Vergine, and 28 miles E. of Naples. It is the see of a bishop, and has a cathedral, several parish churches, a royal college, &c.;—with manufactories of cloth, paper, maccaroni, and sausages, and extensive dye-works. It has a considerable trade in corn, chestnuts, and hazel-nuts. This city has at various times suffered severely from earthquakes. Pop. 16,000. See ABELLINUM.

AVE-MARIA (*Hail Mary*), a form of devotion in the Romish Church, addressed to the Virgin Mary. It is derived from the salutation of the angel in Luke i. The chaplets and rosaries of Roman Catholics are divided into a certain number of *ave-marias* and *pater-nosters*.

AVENA, a botanical genus of Gramineæ, to which the oat, *Avena sativa*, belongs.

AVENBRUGGER, LEOPOLD, an ingenious physician of Grätz, in Styria. We owe to him the important mode of investigating diseases of the chest and abdomen by *auscultation*. His method was to apply the ear to the chest, and to note the sounds it afforded on percussion by the hand, or what is called *immediate ausculation*. His Latin treatise excited but little attention, until it was translated and illustrated by Corvisart, in 1808; when it soon led the way to Laennec's great improvement of aiding the ear by the stethoscope, or *mediate auscultation*. This latter practice, which has so greatly aided the diagnosis of inter-

Avenches || Avenue.

nal diseases, was employed at Edinburgh several years before it was in general use in other parts of Great Britain. Avenbrugger was born at Grätz in 1722, and died in 1809.

AVENCHES (in German, *Wifflisburg*), a small town of Switzerland, in the canton of Vaud, about 1½ miles from Lake Morat or Murten. It is the ancient Aventicum, the chief city of the Helvetii. Many objects of antiquity have been found here; and remains of an amphitheatre, of an aqueduct, and of the ancient walls, still exist. Avenches contains 1100 inhabitants.

AVENOR, in *Feudal Law*, an officer belonging to the king's stables, who provided oats for the horses.

AVENTINUS (or JOHANN TURMAYR), author of the *Annals of Bavaria*, was born in the year 1466, at Abensperg. He studied first at Ingoldstadt, and afterwards in the university of Paris. In 1503 he privately taught eloquence and poetry at Vienna, and in 1507 he publicly taught Greek at Cracow, in Poland. In 1509 he read lectures on some of Cicero's works at Ingoldstadt, and in 1512 was appointed preceptor to Prince Ludwig and Prince Ernst, sons of Albert the Wise, Duke of Bavaria, and travelled with the latter of these princes. He afterwards undertook to write the *Annales Boiorum*, or *Annals of Bavaria*, being encouraged by the dukes of that name, who settled a pension upon him, and gave him hopes that they would defray the charges of the book. This work, which gained its author great reputation, was first published in 1554 by Hieronymus Zieglerus, professor of poetry in the university of Ingoldstadt; and afterwards at Basil, in 1580, by Nicholas Cisner. Besides his other writings, Gesner attributes to him a curious work, entitled *Numerandi per digitos manusque Veterum Consuetudines*. Aventinus died in 1534.

AVENTINUS MONS, one of the seven hills on which ancient Rome stood. The origin of the name *Aventinus* is uncertain; but this hill was also called *Murcius*, from Murcia (Venus), the goddess of sloth, who had a little chapel there; and *Collis Dianæ*, from the temple of Diana; likewise *Remonius*, from Remus, who was buried there. It was taken within the compass of the city by Ancus Marcius (Liv. i. 33.) To the E. it had the city walls; to the S. the Campus Figulinus; to the W. the Tiber; and to the N. Mons Palatinus. It was two miles and a quarter in circuit.

AVENUE (*ad* and *venio*), a walk planted on each side with trees, and leading to a house, garden-gate, wood, &c. The trees most proper for avenues with us are the English elm, the lime, the horse-chestnut, the common chestnut, the beech, the abele. The English elm will do in all grounds, except such as are very wet and shallow; and this is preferred to all other trees, because it will bear cutting, heading, or lopping in any manner, better than most others. The rough or smooth Dutch elm is approved by some because of its quick growth. This is a tree which will bear removing very well; it is also green almost as soon as any plant whatever in spring, and continues so as long as any; it makes an incomparable hedge, and is preferable to all other trees for lofty espaliers. The lime is valued for its natural growth and fine shade. The horse-chestnut is proper for all places that are not too much exposed to rough winds. The common chestnut will do very well in a good soil, and rises to a considerable height when planted somewhat close, though, when it stands single, it is rather inclined to spread than to grow tall. The beech is a beautiful tree, and naturally grows well with us in its wild state; but it is less to be chosen for avenues than the before-mentioned, because it does not bear transplanting well, and is very subject to miscarry. Lastly, the abele is fit for any soil, and is the quickest grower of any forest tree. It seldom fails in transplanting, and succeeds very well in wet soils, in which the others are apt to fail. The oak is but little used for avenues, because of its slow growth. See HORTICULTURE.

Avenzoar || Average.

AVENZOAR (ABU MERWAN ABDALMALEC EBN ZOHR), an eminent Arabian physician, who flourished about the end of the eleventh or the beginning of the twelfth century. He was of noble descent, and born at Seville, the capital of Andalucia, where he exercised his profession with great reputation. He was contemporary with Averroes, who, according to Leo Africanus, heard his lectures and learned physic of him. This seems the more probable, because Averroes more than once gives Avenzoar very high and deserved praise, calling him *admirable, glorious, the treasure of all knowledge*, and *the most supreme in physic from the time of Galen to his own*. Avenzoar, notwithstanding, is by the generality of writers reckoned an empiric; but Dr Freind observes that this character suits him less than any of the rest of the Arabians. Avenzoar belonged, in fact, to the *Dogmatists* or *Rational Sect*, the antipodes of the *Empirics*. He was a great admirer of Galen; and in his writings inveighs against the quackery of old women, and the superstitious remedies of the astrologers. He shows no inconsiderable knowledge of anatomy in his remarkable description of inflammation and abscess of the mediastinum in his own person, and its diagnosis from common pleuritis as well as from abscess and dropsy of the pericardium. In cases of obstruction or of palsy of the gullet, his three modes of treatment are ingenious. He proposes to support the strength by placing the patient in a tepid bath of nutritious liquids, that might enter by cutaneous imbibition; but does not recommend this. He speaks more favourably of the introduction of food into the stomach by a silver tube; and he strongly recommends the use of nutritive enemata. From his writings it would appear that the offices of physician, surgeon, and apothecary were already considered as distinct professions. He wrote a book entitled *The Method of Preparing Medicines and Diet*, which was translated into Hebrew in the year 1280, and thence into Latin by Paravicius, whose version has passed through several editions.

AVERAGE,[1] a term used in maritime commerce to signify damages or expenses resulting from the accidents of navigation. Average is either *general* or *particular*. General average arises when sacrifices have been advisedly made, or expenditures incurred, with a view to the preservation of the ship, cargo, and freight from the effects of some extraordinary peril; and it implies a subsequent contribution from all the parties concerned, in order to make good the loss which one or more of them may thus have sustained. Particular average signifies the damage or partial loss happening to the ship, goods, or freight, in consequence of some fortuitous or unavoidable accident; and it is borne by the individual owners of the articles damaged, or by their insurers.

It may be here remarked, that the term Average was originally used to signify what is now distinguished as General Average. The expression "Particular Average" is not strictly accurate, as it does not, in its current acceptation, imply the idea of an *equalizing contribution*, as originally signified by the word Average. It has, nevertheless, been generally adopted, and is now fully recognised as the distinctive expression for damage or partial loss falling on *some one* of the individuals interested in a sea adventure.

Petty Average consisted of certain small charges for pilotages, light-dues, &c., which were apportioned one-third

[1] Average is said by Cowell to be derived from the Latin word *averagium*, from the verb *averare*, to carry. He supposes it to have been introduced into commerce to show the proportion to be paid by every man according to his goods *carried*. Loccenius, on the other hand, derives it from the French *havre*, or the German haven, a port; it being a contribution paid for having goods *brought safely to port*. (*De Jure Maritimo*, lib. ii. cap. viii. sect. 1.)

Average. to the ship and two-thirds to the cargo; but this is now superseded by the agreement that the freight payable for the cargo shall include all such expenses; and the term has, consequently, become obsolete.

Although nothing can be more simple than the fundamental principle of general average,—which is, that a loss incurred by one party for the advantage of several shall be made good in equitable proportions by all who are benefited by it,—yet the application of this principle to the varied and complicated cases which arise in the course of maritime commerce has occasioned many diversities of usage in different countries, and even in the same country at different periods. Without entering on so wide a field as the discussion of these diversities would open up, we shall endeavour to present a brief summary of the leading principles which have been established in this country, by usage or by legal decisions, in connection with the subject.

All general average losses may be divided into two principal classes:—1. *Sacrifices* of part of the cargo and freight, or of part of the ship, for the general benefit; 2. *Extraordinary expenditures*, incurred with the same object.

Under the first of these classes we shall begin by noticing the acts which involve sacrifices of *part of the cargo and freight.*

When a part of the cargo is thrown overboard (or *jettisoned*, as it is termed) to save the ship from foundering in a storm, or to float her when stranded, or to facilitate her escape from an enemy, the loss of the goods and of the freight attached to them must be made good by average contribution. In like manner, if goods be damaged in the ship by opening the hatches in order to effect a jettison, or by being brought upon deck for that purpose, the damage forms a general average charge. But if goods jettisoned have been originally stowed *on deck*, no contribution can be demanded for them, unless they are so carried according to the common usage and course of trade on the voyage for which they were shipped.

If, instead of being thrown overboard, the goods are put into boats or lighters, and lost or damaged before reaching the shore, such loss is regarded as a virtual jettison, and gives a claim to average contribution. The same rule applies to damage occasioned by the goods being put ashore on muddy ground, as may sometimes happen, when there is no other place where they can be landed.

But when the goods have been conveyed to a place of ordinary safety, they are no longer at the risk of the *general* interest; and should they be damaged by fire or other accidents, the loss must be borne by the *individual* proprietors, or by their insurers.

The loss of corn, salt, guano, or similar goods, arising from their being pumped up or baled out with the water in the vessel, cannot be recovered by average contribution.

If, in consequence of there being no other means of raising money at a foreign port, a part of the cargo be sold for the purpose of repairing losses or defraying expenses which are themselves of the nature of general average, the loss arising from the sale gives a claim to contribution. But if the funds are required for the purpose of repairing particular average losses on the ship, or of defraying the ordinary expenses of the navigation, the loss must be borne by the shipowner.

The damage done to the cargo by means of water thrown down the hatches to extinguish an accidental fire, or by scuttling the ship for that purpose, is excluded, *by usage*, from general average. This point seems to have never yet been settled by any legal decision; and the usage referred to is considered by several writers of high authority to be at variance with sound principle. It is sometimes defended on the ground that the damage in question is *secondary* and *incidental*, and not *primary* and *intentional*. But this reason seems somewhat fanciful for the purposes of equity, and is, besides, inconsistent with the analogy of certain other cases, where an opposite principle is practically recognised; as, for instance, in the case of goods incidentally damaged in effecting a jettison of other goods. Average.

The amount of compensation to be made for goods sacrificed by general average acts is determined by the nett market price they would have produced on arrival at the port of destination had they not been sacrificed; but under deduction of the freight attaching to them (which is made good to the shipowners), and of the charges for duties and landing expenses which are saved.

We now proceed to notice the general average acts which involve sacrifices of part of the *ship or her materials.*

The same principles which regulate the case of goods thrown overboard apply also to the jettison of the ship's chains, anchors, hawsers, spars, boats, or other stores. But if water-casks are stowed on deck, or if chains and hawsers are carried on deck when the vessel is not near the land, so as to render it necessary that they should be so carried, the loss arising from the jettison of these articles falls on the shipowner; and if boats are jettisoned in consequence of their having been broken adrift from their fastenings on deck by the force of the sea, they are excluded from general average, and are charged to particular average on the ship.

The damage done to the ship by cutting holes to effect a jettison of the cargo, or to pour down water to extinguish a fire, or by scuttling her for that purpose, is allowed as a general average charge. The damage arising from cutting or knocking away a portion of the ship's bulwarks in order to prevent the deck from being flooded in a storm, is compensated in the same manner.

When sails or masts are cut away in order to righten a ship which has been thrown on her beam-ends, or to prevent her from driving on a lee shore, the loss is made good by average contribution; but if the object in cutting away a sail or spar be merely to *save a mast*, the loss is not made good in general average.

It frequently happens that masts or yards are sprung and carried away by the force of the wind, and are left entangled in the rigging, or hanging over the ship's side in what is termed "a state of wreck;" in these circumstances it becomes necessary to cut them away, with the sails and rigging attached, and to throw the whole overboard, otherwise they would impede the navigation, and endanger the ship and cargo. On this ground it is held by some authorities that the loss caused by the act of cutting them away should be made good by average contribution. But this act is the direct consequence of the previous accident, which places these articles in a situation where it is impossible to save them without imperilling the ship, cargo, and lives. It would not be reasonable to imperil these for such a purpose; whence it follows that the displaced articles are already *virtually* irrecoverably lost by means of the original accident, before the loss is *actually* consummated by cutting them away. And as the *general* interest ought not to be endangered for the purpose of attempting to save these articles, so neither should it be implicated in the loss resulting from the only remaining alternative of clearing them away. This loss is accordingly excluded, by the usage of this country, from average contribution. On the same principle, no contribution can be demanded for any articles which are sacrificed as having themselves become, through previous accident, the immediate cause of danger to the whole interest.

The loss of sails or spars, in consequence of carrying a press of canvas to avoid a lee-shore, or to escape from an enemy, is not the subject of general average in this country; neither is the damage suffered by the ship from *straining*, under any such extraordinary press of sail.

When anchors and cables are slipped from in order to work a vessel off a lee-shore, or to avoid collision with another ship, the loss is made good by average contribution;

Average. but if the cable is slipped in order that the vessel may join convoy, or because the anchor has become hooked to some object at the bottom and cannot be raised, the loss is borne by the shipowner.

When sails, ropes, or other materials, are cut up and used at sea for the purpose of stopping leaks or to rig jurymasts, or when the common benefit requires that they should be applied to some purpose for which they were not originally intended, the loss is made good in general average. The same rule applies to the case of hawsers, cables, anchors, sails, or boats, lost or damaged in attempting to force off a stranded vessel from the shore.

The damage sustained in defending a ship against a pirate or an enemy is not the subject of general average in this country; it is treated as particular average on the ship.

It has been much debated by writers on maritime law, whether the voluntary stranding of a ship, in order to prevent her from foundering, should be treated as a general or as a particular average loss. In the United States it has been settled, by judicial decision, that the loss in question constitutes a general average claim; but the opposite doctrine is acted upon in the usage of our own country, and the point has never been raised before the courts of law. It appears to us that the argument greatly preponderates against the rule adopted in the United States, and in favour of the usage established in this country. The only reason for regarding this loss as the subject of general average is, that it originates in the intentional act of running the ship aground, for the preservation, as far as possible, of the whole interest concerned. But it can seldom be known beforehand how the different interests at stake will be specially affected by the act in question;—whether, for instance, the damage to the cargo may not be more serious than the damage to the ship, or *vice versa*. Thus no particular part of the interest can be said to be intentionally sacrificed for the benefit of the whole; the intention, indeed, is not to sacrifice any one part, but to place the whole interest in a situation of less peril than it would otherwise have been in. What particular damages may thereafter ensue to either ship or cargo will depend, in each case, on a variety of circumstances entirely accidental in their character, and therefore in no proper sense the subject of previous intention. The same rule, therefore, which excludes from general average accidental damages in all other cases, ought to exclude them in this case also. Moreover, when the alternatives are, either that the vessel be left to founder, or that she be run ashore with a chance of preservation, there can really be no room for choice, or, at all events, the elements of will and intention are entirely subordinate in the part they must play under the pressure of the existing circumstances; and in this view the stranding is as truly inevitable as if it had been caused by the force of the winds and waves alone.

But, even were these reasons less weighty than we hold them to be, a serious practical objection might be urged against the doctrine that voluntary stranding should be a general average loss, on the ground that it would in most cases be impossible to distinguish between the damages received by the ship and cargo prior to the stranding, and those sustained after or in consequence of it. It is needless to remark, that before a ship can be in such imminent danger of foundering as to render it necessary to run her ashore, she must be presumed to have sustained a very considerable amount of damage; and the probability is, that the cargo also will have suffered to a corresponding extent. Up to this point these damages are confessedly *particular* average; and were it held that the damages *after* the stranding were the subject of *general* average, it would, of course, be necessary to distinguish the separate damages that belonged to each. But in every case these different damages would exist in varying proportions, yet always so incorporated together that justice could never have a more perplexing task than that of discriminating between them. No general rule could be applied that would meet the widely different circumstances of each particular case; and the arbitrary method of adjustment that would alone be possible would doubtless give rise to endless dissatisfaction and dispute. On the ground of expediency, therefore, as well as on that of principle, the usage now established in this country ought to be maintained, notwithstanding the high authorities by whom the opposite practice has been countenanced. Average.

The amount of general average losses on the ship is compensated by allowing to the owners the cost of repairs, or of new materials in place of those sacrificed, subject to the deduction of one-third for the difference of value between old and new; but no deduction is made from the cost of new anchors, and only one-sixth is deducted from the cost of new chain cables. If the ship be on her first voyage (which is held to include the homeward as well as the outward passage), the repairs and new materials are allowed in full.

We now proceed to notice the second principal class of general average losses, consisting of extraordinary expenditures incurred with a view to the common benefit.

When a ship is obliged to put into a port of refuge, in consequence of damage received in the course of the voyage, the usage in this country is to allow as general average all the charges connected with the entrance of the vessel into the port, and with the landing and warehousing of the cargo, when this is necessary to admit of the ship being repaired. Thus the expenses of pilotage or other assistance into the port, the harbour dues and similar charges, the costs of the protest taken by the master and crew, and of the survey held to ascertain whether the cargo requires to be discharged, together with the charges for landing the cargo and conveying it to a warehouse or other place of safety, are all made good as general average. The costs of repairing the ship are charged to general average only in so far as the repairs may refer to damages which are themselves the proper subject of general contribution. If the damages are of the nature of particular average, as is more usually the case, they are charged accordingly; or if they proceed from "wear and tear," they are stated against the shipowner.

The warehouse rent for the cargo at a port of refuge, and any expenses connected with its preservation, form special charges against that particular interest, and are borne by the proprietors of the goods, or by their insurers. When goods are insured "free from particular average, unless the ship be stranded," it is necessary, if the ship has not been stranded, to distinguish the charges for warehouse rent and fire insurance from those incurred in connection with the preservation of the goods from the effects of damage; the underwriters being liable for the former, but not for the latter.

The expenses of reshipping the cargo, and the pilotage or other charges *outwards*, are borne by the freight. If the entire cargo cannot be taken on board again, from the want, at the port of refuge, of the usual facilities for stowing it, the loss or expenses resulting from the exclusion of part of it are not treated, in this country, as the subject of general contribution.

The wages and provisions of the master and crew during the period of detention at a port of refuge, are not admitted as a charge against general average; it being held that the shipowner is bound to keep a competent crew on board the ship from the commencement to the end of the voyage at his own expense.

The charges for agency at a port of refuge are brought against the general average, even though they may have been originally made in the form of separate charges against the ship and cargo respectively. Commissions on money advanced, maritime interest on bottomry and *respondentia*, and the loss on exchanges, &c., are apportioned relatively

Average. to the gross sums expended on behalf of the several interests concerned.

The expenses incurred in getting a stranded ship off the ground, the hire of extra hands to pump a ship which has sprung a leak, and the sums awarded for salvage or for other services rendered to the ship and cargo under any extraordinary emergencies, are compensated by average contribution. But this rule applies only to the *extraneous* assistance that may have been obtained; the crew being bound to do their utmost in the service of the ship on all occasions, without extra remuneration for what they might consider extraordinary exertions on their part.

The costs of reclaiming the ship and cargo after having been captured, are allowed as general average charges; and although *ransom* to an enemy is prohibited in this country by legal enactment, it seems that this does not apply to the case of money or goods given up by way of composition to pirates for the liberation of the ship and cargo, and that this would also form a subject of average contribution.

When the ship and cargo arrive at the port of destination, it is unnecessary, in ordinary cases, to distinguish, in the adjustment of the general average, between the losses which have arisen from *sacrifices*, and those which have resulted from *expenditures* for the common benefit. But if the ship and cargo should be lost before reaching their destination, no contribution is due for the goods or ship's materials which may have been *sacrificed* at a former stage of the voyage, the owners of these being in no worse position than any of their coadventurers. On the other hand, it is evident that when money has been *expended* for the common benefit, the subsequent loss of the ship and cargo should not affect the right of the party who has made the advance to recover it in full from all the parties for whose advantage it was originally made. Hence, while *sacrifices* are made good only in the event of the ship and cargo being ultimately saved, *expenditures* must be reimbursed whether the ship and cargo be eventually saved or lost; and the contribution for these expenditures must be regulated by the values of the ship, cargo, and freight, as they stood at the time when the advances were made.

If, however, the money required for average expenditures has been raised by means of bottomry, and the ship be lost before completing the voyage, there can be no claim for reimbursement; the risk being assumed by the bottomry lender in consideration of the premium he receives on the sum advanced. It is by no means clear that the average expenditures which have been advanced without any contract of bottomry form a specific insurable interest, according to the law of this country, although in practice they are very frequently insured. When this has been done, and when the amount has been recovered on the subsequent loss of the ship, no claim can be *equitably* made against the individuals who would otherwise have been liable. But if the expenditures are not insured, either by a bottomry contract, or by a special policy, and if the ship and cargo be totally lost in the subsequent course of the voyage, the parties for whose benefit the expenditures were incurred must reimburse them on the principles already explained. These parties, however, have recourse on their original insurers, not only for the total loss of the interests insured, but also for the previous expenditures, although the insurers may thus be called on to pay a *larger sum* than the amount of the insurance.

The contribution for general average losses is regulated by the values of the respective interests for the benefit of which they were incurred. The practical rule adopted, in all ordinary cases, is to estimate the ship, cargo, and freight, at their *nett* values to their owners, in the state in which they arrive at the port of destination, *but including in these values the sums made good for sacrifices*, and to assess the contribution accordingly The necessity for including the amount of compensation made for sacrifices in the valuations on which the contribution is charged, arises from the principle that all the parties interested in the adventure should bear the ultimate loss in exact proportion to their respective interests, which would not be the case if the owners of the articles sacrificed were to recover their full value without being themselves assessed for the loss thereon in the same manner as their coadventurers. Average.

The contributory value of the *ship* is accordingly her actual value to her owner in the state in which she arrives, whether damaged or otherwise, including the sum made good in the general average for any sacrifices which may have been made of part of the ship or her materials.

The value of the *cargo* for contribution is its nett market value on arrival, after deducting the charges incurred for freight, duty, and landing expenses, but without deducting the costs of insurance or commission. If goods be damaged, they contribute only according to their deteriorated value; and if special charges have been incurred on the cargo at a port of refuge (as for warehouse rent, &c.), the amount of these charges is deducted. The sum charged to general average for goods sacrificed is of course added to the valuation. All goods carried in the ship for the puposes of traffic must be included in the valuation of the cargo; but the wearing apparel, or personal effects, of the passengers and crew are exempted from contribution.

The value of the *freight* for contribution is the sum received by the shipowner on the completion of the voyage for the carriage of the cargo, after deducting from that sum the wages then due, the port charges at the place of destination, and the special charges against the freight which may have been incurred at a port of refuge, consisting of the costs of reshipping the cargo, and of outward pilotage, &c. The provisions for the voyage are not deducted, as these are held to have formed part of the original value of the *ship*. If the freight has been paid in advance, it forms part of the value of the *goods*, and, consequently, does not contribute as a separate interest. It has been decided, that when a vessel has been originally chartered for a double voyage, the *whole* freight to be earned under the charter-party must contribute at its nett value, after deducting the wages and other charges which must be incurred in earning it. The effect of this rule is to render the freight attaching to the *return* voyage, as well as that attaching to the voyage *outwards*, liable to contribute for average losses arising in the course of the outward passage; a result the equity of which is not always very apparent.

An adjustment of general average made at any foreign port where the voyage may terminate, if proved to be in conformity with the law and usage of the country to which such foreign port belongs, is binding on all the parties interested as coadventurers, although they may be subjects of this country, and although the adjustment may be made on principles different from those sanctioned by the laws or usages of Britain. The reason for this rule is, that the parties engaging in the adventure are held to assent to the known maritime usage according to which general average is adjusted on the arrival of the ship and goods at the port of destination.

The subject of general average is only incidentally connected with that of marine insurance, being itself a distinct branch of maritime law. But the subject of particular average arises directly out of the contract of insurance, and will therefore be best considered in connection with it. (See INSURANCE, MARINE.)

For further information with respect to the subject of average, the reader is referred to the famous work of M. Valin, *Commentaire sur l'Ordonnance de* 1681, tome ii. p. 147–198, ed. 1760; to Emerigon, *Traité des Assurances*, tome i. p. 598–674; Park *On Insurance*, chap. vii.; Marshall *On Insurance*, book i. chap. xii. sect. 7; Stevens's

AVERNUS, a lake of Campania in Italy, near Baiæ, occupying the crater of an extinct volcano, and about a mile and a half in circumference. It is described by Strabo as situated within the Lucrine Bay, deep and darksome, surrounded with steep overhanging banks, and only accessible by the narrow passage through which you sail in. Black aged groves stretched their boughs over the watery abyss, and with impenetrable foliage excluded almost every ray of wholesome light; and mephitic vapours ascending from the hot bowels of the earth, being denied free passage to the upper atmosphere, floated along the surface in poisonous mists. Hence these gloomy shades were regarded as sacred to the infernal gods; while a colony of Cimmerians, as well suited to the rites as the place itself, cut dwellings in the bosom of the surrounding hills, and officiated as priests of Tartarus. Superstition, always delighting in dark ideas, early and eagerly seized upon this noxious spot, and hither she led her trembling votaries to celebrate her dismal orgies. Here she evoked the manes of departed heroes; here she offered sacrifices to the gods of the infernal regions, and attempted to dive into the secrets of futurity. Poets enlarged upon the popular theme, and painted its awful scenery with the strongest colours of their art. Homer brings Ulysses to Avernus; as to the mouth of the infernal abodes; and, in imitation of the Grecian bard, Virgil conducts his hero to the same gloomy regions. Whoever sailed thither, first did sacrifice, and endeavoured to propitiate the infernal powers, with the assistance of some priests, who attended upon the place and directed the mystic performance. Within, a fountain of pure water broke out just over the sea, which was fancied to be a vein of the River Styx. Near this fountain was the oracle; and the hot waters, frequent in those parts, were supposed to be branches of the burning Phlegethon. The poisonous effluvia from this lake were said to be so strong that they proved fatal to birds endeavouring to fly over it. Hence the name is said to be derived from ἄορνος, i. e. *without birds.* Virgil ascribes the exhalation, not to the lake itself, but to the cavern near it, which was called *Avernus*, or *Cave of the Sybil*, and through which the poets feigned a descent to Orcus. Others say the proper name of the lake is *Lacus Averni*, the lake near the cavern, as it is called by some ancient authors. It is still called *Lago Averno.*

The sanctity of these shades remained unimpeached for many ages. Hannibal marched his army to offer incense at this altar; but, according to Livy, he was led to this act of devotion rather by the hopes of surprising the garrison of Puteoli, than by his piety. After a long reign of undisturbed gloom and celebrity, a sudden glare of light was let in upon Avernus; the horrors were dispelled, and with them vanished the sanctity of the lake. The axe of Agrippa levelled its forest with the ground, disturbed its sleepy waters with ships, and gave room for all its malignant effluvia to escape. The virulence of these exhalations, as described by ancient authors, has appeared so very extraordinary, that some modern writers, who know the place in a cleared state only, charge these accounts with exaggeration; but others think them entitled to more respect, since even now the air is feverish and dangerous, as the jaundiced faces of the vine-dressers, who have succeeded the Sybils and Cimmerians in the possession of the temple, most ruefully testify. It would appear that the ancients regarded Avernus as a divinity, to whom they offered sacrifices. (See SERVIUS, *ad Virg. Georg.* ii. 161.)

AVERROES (a corruption of IBN-ROSHD), the most illustrious of Arabian philosophers, was born, according to El Ansari, in the year of the Hegira 520 (A.D. 1120), at Cordova, of one of the best families in Andalucia. His grandfather and father successively held the office of cadi in Cordova, a dignity which Averroes himself also enjoyed for many years. After studying theology and jurisprudence, he applied himself with zeal to mathematics, medicine, and philosophy. His preceptor in the latter was the celebrated Avenpace (Ibn-Badja). The sudden overthrow of the dynasty of the Almoravides in 1130 by the Almohades was favourable to the interests of science; and Averroes enjoyed, with his friends Ibn-Tofail and Ibn-Zohar, the patronage successively of Abdal-Mumen, Yusuf, and Almansur. In 1169 he was appointed cadi of Seville, and about this time he began to employ his leisure in the composition of the works to which he owes his celebrity. In 1182 he was called to Marocco, to fill the office of physician to the Sultan Yusuf; but some time after returned to Spain as cadi of Cordova. Under Yusuf's son, Almansur, he long enjoyed the highest favour; but towards the close of his life the jealousy of his enemies procured his banishment to Elisana (Lucena), a town not far from Cordova. The charge brought against him was that he corrupted the minds of his pupils by impious and heterodox doctrines. Another version attributes his disgrace to a careless expression in his commentary on Aristotle's Zoology, which had offended the pride of Almansur. He had called the sultan simply *King of the Berbers*, which was construed into an insult to the sovereign both of Spain and of Marocco. Averroes, however, was soon restored to favour, and returned once more to the court of Marocco, where he died in 1198, at an advanced age.

Averroes

The fame of Averroes is mainly connected with his commentaries on the works of Aristotle, which procured him the same title bestowed in a former age on Alexander the Aphrodisian, of *The* Commentator. To this distinction, alike by the extent and the quality of his labours, he is well entitled. Without pretending to found a system distinct from that of his great master, he modified with the rest of the Arabian philosophers the Aristotelian doctrines, by the infusion of new elements derived from Neo-Platonism. It may be mentioned, that Averroes wrote also a commentary on the *Republic* of Plato. Though professedly a Mussulman, the tendency of his doctrines was such as not unreasonably to call his orthodoxy in question. Holding that what was true in religion was not necessarily so in philosophy, he seems to have regarded the one as but a system of exoteric doctrine, of which the other was the proper interpreter and the final consummation.

Arabian philosophy attained its culminating point in Averroes, and after him no eminent name is found in its history. His doctrines were long of high authority in the Jewish and even in the Christian schools. They gave rise in the thirteenth century to great contentions, which continued till the sixteenth century, when Leo X. issued a bull against them in 1512. The disputes were carried on principally between the followers of Alexander of Aphrodisias, or Alexandrians, and the Averroists, or professed disciples of the Arabian philosopher. One of the chief points on which the latter laid themselves open to the charge of heresy, was the immortality of the soul. Among others Albert the Great and Aquinas wrote treatises against the principles of Averroes.

Many of the treatises of Averroes have never been printed. The first complete Latin edition of his works, containing also the Latin of the Aristotelian text, is that of Mantinus, a Jewish physician, in 11 vols. fol., Venice, 1552. The first eight volumes contain the *Commentaries;* the ninth, besides two other treatises, the *Destruction of the Destruction*, written in reply to Algazel (see ALGHIAZZALI); and the tenth is chiefly taken up with his great medical work the *Colliget* (*Kulliyyat.*) The last contains miscellaneous treatises. There have been numerous

Averrunci || Avianus.

editions of separate treatises of Averroes. (Brucker, *Hist. Crit.* iv. 62, Leipz.; Tennemann, *Geschichte der Philos.; Dict. de Sc. Philos.;* Wüstenfeld, *Geschichte der Arab. Aertze*, Götting. 1840; Renan's *Averroes et l'-Averroisme*, Paris, 1852.)

AVERRUNCI (Dei), in *Pagan Mythology*, a name given to certain gods who were specially invoked to avert misfortunes; as Apollo and Hercules among the Greeks, and Castor and Pollux among the Romans.

AVERSA, a town of Naples, province of Terra di Lavoro, situated in a beautiful plain covered with orange-groves and vineyards, about midway between Naples and Capua. It is the seat of a bishopric, said to be the richest in the kingdom, and its foundling hospital and lunatic asylum are very celebrated. Pop. 16,000.

AVESBURY, Robert of, an English historian, of whom little more is known than that he was a keeper of the registry of the court of Canterbury in the reign of Edward III. He wrote a history in Latin of the reign of that prince, ending with the battle of Poictiers, in the year 1356. It was printed at Oxford in 1720 by Hearne.

AVESNES, an arrondissement in the department of Nord, in France, containing 10 cantons and 152 communes. Pop. in 1851, 145,046. The capital, of the same name, is situated in a fertile district on the Greater Helpe. It is generally well built, and is fortified on Vauban's system. Its principal building is the cathedral, surmounted by a tower 330 feet high, which is raised on four columns, and has a fine chime. It is the seat of a sub-prefect, and has a tribunal of primary jurisdiction, an agricultural society, and a communal college. Pop. in 1851, 2946. The principal manufactures are hosiery, coarse serge, and soap; there are also breweries, tanneries, salt-refineries, and brick and marble works. A great part of the town was destroyed by the explosion of a powder-magazine during the siege by the Prussians in July 1815.

AVESTA, a mining village of Sweden, on the Dal-elf, 35 miles S.E. of Fahlun. It has extensive copper and iron founderies, cloth manufactories, and saw-mills. The copper coin of the country was formerly struck here. Pop. 700.

AVEYRON, a department in the S. of France, in the ancient province of Guienne. Area 3429 square miles. It is divided into five arrondissements as follows:—

Arrond.	Cantons.	Communes.	Pop., 1851.
Rodez.....	11	75	108,588
Espalion	11	43	67,698
Milhau.....	7	46	65,625
St Affrique	6	41	60,038
Villefranche	7	54	92,234
	42	259	394,183

A portion of this department is mountainous, but about one-half is under cultivation, nearly one-fourth heath, one-tenth woods and forests, and rather more than an eighth part meadow land. Vineyards occupy about one-twelfth part of the cultivated land. It has mines of copper, lead, silver, iron, zinc, and antimony; besides considerable coal-fields of great value. The inhabitants are extensively engaged in the rearing of cattle; and there are manufactures of paper, woollen and cotton goods, and leather, to which water-power is skilfully applied. Aveyron exports corn, chestnuts, almonds, hemp, wool, wax, cheese, timber, and cattle. The capital is Rodez.

AVEZZANO, a town of Naples, in Abruzzo Ulteriore II., containing a castle belonging to the Colonna family. Pop. about 3000. Long. 13. 32. E. Lat. 41. 58. N.

AVIANUS or Anianus, *Flavius*, the reputed author of 42 Æsopean fables in Latin elegiac verse. They are of little merit, and apparently belong to the third or fourth century of our era. *Editions.* By Cannegieter, Amstel. 1731; Nodell, Amstel. 1787; Lachmann, Berol. 1845. They were translated into English by Caxton in 1483.

Aviary || Avicenna.

AVIARY, a place set apart for feeding and breeding birds. Aviaries are of various kinds, being sometimes artificially warmed to adapt them for exotic birds. They are occasionally of great extent, inclosing large trees by means of netting thrown over them.

AVICENNA (a corruption of Ibn-Sina), a celebrated Arabian physician and philosopher, honoured with the title of *Sheikh-al-rais*, or the *prince of physicians*, was born at Afshena, near Kharmeithan, a city of Bokhara, where his father, a native of Balkh in Persia, held the office of governor. After some years his father returned to the city of Bokhara, and here Avicenna was educated with extreme care. At the age of ten he was already perfectly versed in the theology of the Koran, in arithmetic, algebra, and the principles of grammar and law. Abu-Abdallah Nathili, a native of Naplous in Syria, at that time professed philosophy at Bokhara with high reputation. Under him Avicenna studied Porphyry's *Introduction to the Categories of Aristotle*, Euclid's *Elements*, and the *Almagest* of Ptolemy; and having soon surpassed the attainments of his master, he began to study the higher sciences alone. In philosophy he devoted himself chiefly to the works of Aristotle, whose *Metaphysics* he is said to have read *forty* times before he fully apprehended the meaning. At the age of 16, he was seized with a passion for natural philosophy and medicine, which he studied under a Christian physician named Ben-Yahya. After some time he resumed his philosophical studies with so much ardour, that for a year and a half he never slept for a whole night at a time. At the age of 18 he had acquired so high a reputation that the Emir Nouk Ibn-Mansur, who was a sufferer from severe disease, put himself under his care, and derived so much benefit from his skill, that Avicenna was loaded with favours. Among these not the least was the use of the rich library of the prince, in which he found opportunity for perfecting himself in scientific knowledge. This library was some time after consumed by fire, an accident which was maliciously attributed to Avicenna, who was accused of wishing to destroy the works by which he had so amply profited. At the age of 21 he composed a complete body of science, with the exception of mathematics, to which he gave the name of the *Collection*. On the death of his father, whom he had latterly assisted in his public duties, he quitted Bokhara and lived for some time in Djordjan, and other towns of Kharasm and Khorassan. At Djordjan he formed the acquaintance of Abu-Mohammed Schirazi, a powerful patron of science, who gave him a house, in which he delivered public lectures on logic and the *Almagest*. Here Avicenna wrote several treatises for his friend, and began his great work the *Canon of Medicine*. On leaving Djordjan he changed his residence several times, and finally settled at Hamadhan, the prince of which, Schems-ed-Daulah, in reward for his medical services, made him his vizier. Having given dissatisfaction to the emir's troops, he was forced to retire into concealment, but was soon recalled, and restored to all his honours. Every evening he gave lessons in philosophy and medicine, at the conclusion of which musicians and dancers were called in, and the rest of the evening was spent in festivity. During this time he composed his great philosophical work the *Al-Schefa*, and continued to write the *Canon*. After the death of Schems-ed-Daulah, Avicenna lost favour at court, and having been convicted of secretly corresponding with the prince of Ispahan, he was shut up in a fortress. He succeeded at length in making his escape, and found his way to Ispahan, where he enjoyed an honourable repose during the last fourteen years of his life, during which time he composed the greater part of his numerous works. He accompanied his new master in numerous warlike expeditions,

Avienus || Avila.

the fatigues of which finally subdued a constitution injured by severe study and excess. Seeing his end approaching, he distributed his goods among the poor, freed his slaves, and betaking himself to devotion, prepared to die as a good Mussulman. He died at Hamadhan in the 428th year of the Hegira (A.D. 1036) in the 57th year of his age. His excesses and infirmities gave rise to the saying, that the profound study of philosophy had not taught him good morals, nor that of medicine the art of preserving his own health.

Avicenna, after his death, enjoyed so great a reputation, that till the twelfth century he was preferred for the study of philosophy and medicine to all his predecessors. Even in the schools of Europe his writings were held in high esteem. Of his works, said to amount to more than a hundred, the principal are his *Canon of Medicine*, which long enjoyed an immense reputation as a body of medical science, and has been often reprinted in a Latin translation; and the *Al-Schefa* or *Healing*, an encyclopædia of philosophy, of which the greater part exists in MS. in the Bodleian library. (Abulfarag. *Hist. Orient.* ed. Pocock, Oxon. 1672; Ibn-Khallikan, *Dict. Biogr.* ed. M. de Slane, Paris, 1842; Casiri *Biblioth. Arab. Hisp.*; Aboulfeda, *Annales*, Copenh. 1789; *Mines de l'Orient*, t. iii. p. 167.)

AVIENUS, Rufus Festus, a Latin poet, who appears to have flourished in the latter half of the fourth century. He is the author of the following works:—1. *Descriptio Orbis Terræ*, sometimes called *Metaphrasis Periegeseos Dionysii*, being derived from the περιήγησις of that writer; 2. *Ora Maritima*; 3. *Aratea Phænomena*, and *Aratea Prognostica*, which are paraphrases of two works of Aratus. These poems, with the exception of the last two, are contained in Wernsdorf's *Poëtæ Latini Minores*, vol. v. pt. ii.

AVIGLIANO, a town of Naples, province of Basilicata, 11 miles N.N.W. of Potenza. It stands on the declivity of a hill, and has a fine collegiate church, several convents, and a royal college. The surrounding country is said to produce the finest cattle in the kingdom. A part of the town was destroyed by a land-slip in 1824. Pop. 9000.

AVIGNON, an arrondissement in the department of Vaucluse, in France, divided into 5 cantons and 20 communes; area 124,304 acres. Pop. in 1851, 78,382. The capital, of the same name, is situated in a beautiful valley on the left bank of the Rhone. It is surrounded by walls planted with trees, which form an agreeable promenade. The houses are old but large, the streets narrow and crooked; but several of the public edifices are magnificent, particularly the cathedral and the ancient palace of the popes. Pop. 31,812. It is the seat of an archbishop, and has tribunals of primary jurisdiction and commerce, a royal college, a theological seminary, a society of arts, a normal school, a public library, theatre, &c. The chief object of industry is the preparation of silk, and the manufacture of silk goods; there are also manufactures of paper, leather, hats, jewellery, &c. Till the French revolution this city belonged to the papal see, and was the residence of the several popes from 1303 to 1376. It was seized by the republicans in 1791, and after some barbarous proceedings was at length united to France. The name of Petrarch is associated with Avignon; and here he first beheld the Laura whom he has immortalized. Long. 4. 52. 20. E. Lat. 43. 56. 58. N.

AVILA, a province of Spain, one of the modern divisions of the kingdom of Old Castile. It is situated between Long. 4. 14. and 5. 55. W., and Lat. 40. 48. and 41. 18. N.; and is bounded on the N. by Valladolid; E. by Segovia and Madrid; S. by Toledo and Caceres; and W. by Salamanca. Area 277 square leagues; population in 1849, 132,936. It contains one city, 72 towns, 326 villages, and 334 parishes. It is judicially divided into 6 districts or *partidos*; but naturally consists of two sections, differing completely in soil, climate, productions, and social economy. The northern portion, comprehending the Moraña, the district of Arevalo, part of Avila and Piedrahita, and the plain of Pajares, is generally level; the soil is of indifferent quality, strong and marly in a few places, but in all the valleys of the Sierra de Avila, rocky; and the cold of winter is compensated by extreme heat in summer. The population of this part is agricultural. The southern division, comprehending the districts of Arenas de San Pedro, Cebreros, Barco, and part of Piedrahita and Avila, is one mass of rugged granitic *sierras*, interspersed, however, with sheltered and well-watered valleys, abounding with cattle and rich vegetation. The winter here, especially in the elevated region of the Paramera and the waste lands of Avila, is long and severe, but the climate is not unhealthy. The inhabitants live by the rearing of cattle. The principal mountain chains are the Guadarrama, separating this province from Madrid, and the Sierras de Avila, a continuation of them westward, the Sierra de Gredos, running from the S. of Piedrahita through Barco, Arenos, and part of Cebreros, and the Paramera, stretching southwards from the city of Avila into Arenas and Cebreros. The various ridges which ramify from the latter are covered with wood, presenting a striking contrast to the bare peaks of the Sierra de Gredos, and the barren levels in which they rise on the N. The principal rivers are the Alberche, flowing through the districts of Piedrahita and Avila towards Madrid and Toledo; the Tormes, through Piedrahita and Barco into Salamanca; the Corneja, from E. to W. through the valley of the same name and joining the Tormes; the Adaja, rising at the foot of the Pass of Villatoro, flowing through the valley of Ambles, and entering Valladolid; and the Tietar through Cebreros and Arenas into Caceres. The mountains contain silver, copper, iron, and lead, but their mineral wealth has been greatly exaggerated, and has not yet been subjected to any continued trial. Quarries of fine marble and jasper exist in the district of Arenas.

Avila || Aviles.

This once flourishing province has gradually declined in wealth and population during the last two centuries, a result due less to the want of activity on the part of the inhabitants than to the oppressive manorial and feudal rights and the strict laws of entail and mortmain, which have acted as barriers to improvement. The principal production is the wool of the Merino sheep, which at one time yielded an immense revenue. Game is plentiful, and the rivers abound in fish, especially trout. There is little trade, and the manufactures are few, consisting chiefly of copper utensils, lime, soap, cloth, paper, combs, &c. The state of elementary education is comparatively good, and the ratio of crime is proportionately low. (Madoz, *Diccionario de España.*)

Avila (ancient *Abula*), a city of Spain, the capital of the above province, is situated on the right bank of the Adaja, about 3000 feet above the sea-level, at the termination of the Guadarrama Mountains. It is surrounded by an ancient wall still in good preservation, about two miles in circumference, crowned by a breastwork, with towers of great strength. Avila is the seat of a bishop suffragan to Santiago, and has a Gothic cathedral, 8 parish churches, several monasteries and schools, an infirmary and a foundling hospital. It was formerly the seat of a university, and had large woollen manufactures, but its institutions and industry have greatly decayed. The inhabitants now maintain about 15,000 head of sheep. This is the birthplace of Sta Teresa de Jesus, the patroness of Spain. Pop. 4121.

Avila, *Gil Gonzalez d'*, a Spanish biographer and antiquary, born at Avila about the year 1577, died in his native city in 1658. He was made historiographer of Castile in 1612; in 1641 he was made, in addition, historiographer of the Indies. Among his numerous works, the most valuable are his *Teatro de las Grandezas de Madrid* (Madrid, 1623, fol.), and his *Teatro Eclesiastico*, descriptive of the metropolitan churches and cathedrals of Castile, with lives of the prelates. (Madrid, 1645–53, 4 vols. 4to.)

AVILES, *San Nicolas de*, a town of Spain, province of

Avison ‖ Avon.

Oviedo, about a league from the sea-coast, in Lat. 43. 34. N. Long. 5. 58. W. It has a considerable trade by means of its port, which affords good anchorage for all classes of vessels; and has been chosen as the terminus for the great North of Spain Railroad to Madrid. A line of steam packets between Falmouth and Aviles will thus bring London and Madrid within four days of each other, should that line ever be completed. There are here some copper works, and in the neighbourhood are veins of iron and coal, which, however, have not been worked. The stone quarries are extensive and productive. Aviles has two parish churches, a theatre, and an excellent public school, with an attendance of 400 pupils. Pop. 5600.

AVISON, CHARLES, an organist at Newcastle-on-Tyne, was a pupil of Geminiani, that able violinist, but dry and uninteresting composer. In 1752, Avison published *An Essay on Musical Expression*, in which he had the amazing folly to hold up his master as superior to Handel. It appears that this book was not written by himself, but by his friends Dr John Brown and William Mason. Dr William Hayes, Professor of Music at Oxford, published in 1753 *Remarks* on Avison's Essay, in which he severely criticised the latter, as well as Avison's musical compositions. Avison replied unsatisfactorily in a second edition of his Essay, in the same year. Avison's music has little merit; but he did a service to the art, by pointing out in his essay the excellence of B. Marcello's music to the psalms, and by proposing their republication in England with English words. Mr John Garth, organist at Durham, undertook to do this, and, aided by an extensive subscription, completed the work in eight volumes folio. Avison died at Newcastle in 1770. (G. F. G.)

AVIZ, a walled town of Portugal, on the river of the same name in Alentejo, and containing about 1500 inhabitants. It is still the headquarters of the knights of the order of *Avis*, founded by Alphonso I. in 1146. Its defences are in ruins.

AVLONA or VALONA, a town and seaport of Albania, capital of the pashalic of the same name. It stands on an eminence near the Gulf of Avlona, an inlet of the Adriatic, and has a fort in Lat. 48. 27. 5. N. Long. 19. 26. 5. E. The port, which is protected by the island of Sasseno, is the best on the Albanian coast. Population, including suburbs, about 9000, comprising Christians, Turks, and Jews. The Christian population are principally engaged in commerce, and the Turks in the manufacture of woollen stuffs and arms. The material imported into this country for tanning, under the name of *Valonia*, is the pericarp of an acorn produced in that country.

AVOIRDUPOIS, the name of a weight, derived from the French, *avoir du poise, to have weight*. Its pound contains 16 ounces, in distinction to the pound troy which has only 12. This weight is used for groceries and all other commodities except the precious metals, gems, and medicines. The pound avoirdupois contains 7000 grains troy, and is equal to 8532·5 Paris grains. See WEIGHTS and MEASURES.

AVOLA, a city on the coast of Sicily, in the intendancy of Syracuse, with 7000 inhabitants. There are sugar plantations near it; and it has some trade in wine, grain, oil, honey, &c.

AVON, a Celtic word signifying a river, is the name of several rivers in Britain, the principal of which are:—1. UPPER AVON, which rises at Avon-well, near Naseby, in Northamptonshire, flows through the counties of Leicester, Warwick, and Worcester, passing Stratford and Evesham, and falls into the Severn at Tewkesbury. Its length is nearly 100 miles, and it is navigable for barges of 40 tons up to Stratford. Its principal affluents are the Alne, the Leame, the Stour, the Sow, and the Swift.—2. LOWER AVON rises near Tetbury, flows westward through the counties of Gloucester, Wilts, and Somerset, and passing Bristol enters the Bristol Channel 10 miles below that city, after a course of about 80 miles.—3. AVON, HAMPSHIRE, rises near Devizes, flows generally southward through Wiltshire and Hampshire, and falls into the English Channel a little below Christchurch, after a course of 65 miles.

Avranches ‖ Axholm.

AVRANCHES, an arrondissement in the department of Manche, in France, containing 9 cantons and 123 communes. Area 243,292 acres. Pop. in 1851, 117,032. The chief town, Avranches (*Abrincæ*), was in the time of the Romans an important military station, and has in more modern times sustained several sieges. It stands on a wooded hill, commanding a fine view of the bay and rock of St Michel, about three miles distant. At the foot of the hill flows the River Seez, which at high tide is navigable from the sea. The principal trade is in corn, cider, and salt. Avranches was formerly a bishop's see; and its cathedral, destroyed in the time of the first French Revolution, was the finest in Normandy. Its site is now occupied by an open *place*, called after the celebrated Huet, Bishop of Avranches. The agreeable situation and climate of this town make it a favourite residence of English families. Pop. 8580.

AWARD, in *Law*. See ARBITRATION.

AWE, LOCH, a large and picturesque fresh-water lake of Scotland, in the county of Argyle, eight miles N.W. of Inverary. It is 24 miles in length, with an average breadth of 1 mile, and is surrounded by lofty mountains of a rugged and savage aspect, the highest of which (Ben Cruachan) rises to the height of 3670 feet. It receives several small streams, one of which connects it with Loch Avich, a small lake about 6 miles long, 3 miles distant. The Awe, a small river 7 miles in length, connects it with Loch Etive, an arm of the sea, at Bunawe. Loch Awe contains about 24 small islands, some of them beautifully crowned with trees. On one of these, Innis Aill', or the Beautiful Isle, are the ruins of a small Cistercian nunnery, and an old churchyard, containing a number of ancient tombstones curiously carved. On Innis Fraoch, or the Heather Isle, are the ruins of an ancient castle, once the residence of the chief of the Macnaughtans. The ruins of the celebrated castle of Kilchurn stand on a slightly elevated neck of land at the head of the lake. Its square tower is said to have been erected in 1443 by the lady of Sir Colin Campbell, the Black Knight of Rhodes, and founder of the powerful family of Breadalbane. So late as 1745 Kilchurn was garrisoned by the king's troops, and all the exterior and the greater part of the interior walls are still entire. The lake abounds in fish, and is especially famed for the size and excellence of its trout.

AXAMENTA or ASSAMENTA, in *Antiquity*, verses or songs of the *Salii*, which they sung in honour of Mars, certain other gods, and heroes. The *axamenta* were not composed, as some have asserted, but only sung by the *Salii*. They were as old as the Roman state, but tradition made Numa their author. They grew in time so obscure that the *Salii* themselves did not understand them. Varro, *De Ling. Lat.*, vii. p. 285; Quint., *Inst. Or.*, lib. i. c. 11.

AXBRIDGE, a market-town, formerly a borough, in the county of Somerset, 130 miles from London. It is situated on the river Axe, below the range of the Mendip hills, near the great chasm known by the name of Chedder Clift. The church is a large Gothic edifice of great antiquity, near which stands the market-house. Market-day, Saturday. Pop. in 1851, 939.

AXE, a carpenter's instrument for hewing wood. It is furnished with a long handle or helve, for the purpose of being used with both hands. The small axe for one hand is called a hatchet.

AXEL, a small fortified town of Holland, province of Zealand. Long. 3. 54. E. Lat. 51. 16. N.

AXHOLM, an island in the N.W. part of Lincolnshire, England, formed by the rivers Trent, Idle, and Don. It is

about 17 miles in length by 5 in breadth, and comprises the parishes of Althorpe, Belton, Crowle, Epworth, Haxey, Luddington, and Owston.

AXILLA, in *Anatomy*, the armpit, or the cavity under the upper part of the arm. See ANATOMY.

AXIM, a town on the Gold Coast of Africa, belonging to the Dutch. Lat. 4. 52. N. Long. 2. 14. W.

AXINOMANCY, AXINOMANTIA, (from ἀξίνη, *an axe*, and μαντεία, *divination*;) an ancient species of divination, or a method of foretelling future events by means of an axe or hatchet. This art was in considerable repute amongst the ancients, and was performed, according to some, by laying an agate stone on a red-hot hatchet, and also by fixing a hatchet on a round stake so as to be exactly poised; then the names of those suspected were repeated, and he at whose name the hatchet moved was pronounced guilty.

AXIOM, AXIOMA (from ἀξιόω, *I account worthy*), a self-evident truth, or a proposition the truth of which every person perceives at first sight; as, *the whole is greater than its part; a thing cannot at the same time be and not be; from nothing nothing can arise.* Every science has its particular axioms or elementary principles, which are assumed as the necessary basis of all reasoning. Thus, it is an axiom in physics, that nature does nothing in vain; that effects are proportional to their causes, &c. It is an axiom in geometry, that things equal to the same thing are also equal to one another; that if to equal things you add equals, the sums will be equal, &c. And it is an axiom in optics, that the angle of incidence is equal to the angle of reflection, &c.

AXIS, in *Geometry*, the straight line in a plain figure, about which it revolves, to produce or generate a solid. Thus, if a semicircle be moved round its diameter at rest, it will generate a sphere whose axis is that diameter.

AXIS, in *Astronomy*, is an imaginary right line through the centre of the earth, or through that of a heavenly body, about which it performs its diurnal revolutions.

AXIS, in *Conic Sections*, a right line dividing the section into two equal parts, and cutting all its ordinates at right angles.

AXIS, in *Mechanics*. The axis of a balance is that line about which it moves, or rather turns about. *Axis of oscillation* is a right line parallel to the horizon, passing through the centre, about which a pendulum vibrates.

AXIS in Peritrochio (περὶ *about*, and τροχὸς, a *wheel*), one of the six mechanical powers, consisting of a peritrochium or wheel concentric with the base of a cylinder, and moveable together with it about its axis. See MECHANICS.

AXIUS, a river of Macedonia, now the Vardar, falling into the Gulf of Salonichi.

AXMINSTER, a market-town in the hundred of the same name, county of Devon, 147 miles from London, and 24 from Exeter. It takes its name from the river Axe, on which it stands. The ancient abbey church or minster which ornaments the centre of the town, was built by King Athelstane to commemorate a victory over the Danes. The town is distinguished for its manufactory of the best and most costly description of carpets; and has also manufactures of broad and narrow cloths, cotton, leather, gloves, tapes, and druggets. Market-day, Saturday. Pop. in 1851, 2769.

AXUM, the old capital of Abyssinia. There is here a monolith obelisk 60 feet high, covered with hieroglyphics, but different from those of Egypt. See ABYSSINIA.

AY, or AI, a town of France, 5 leagues S. of Rheims, in the department of Marne. It is celebrated for its wines, which are esteemed superior to any in Champagne. Pop. 3382.

AYACUCHO, a plain in Peru, on which the power of Spanish South America was broken by the republicans in 1824. The viceroy, 15 generals, and 3200 men were made prisoners.

AYAMONTE, a city of Spain, in the province of Huelva, on the left bank of the Guadiana, which empties itself into the ocean about two miles from this place. Ayamonte is well fortified, and the harbour is good, but, on account of a bar at its mouth, it is of difficult entrance. The principal employment of the inhabitants is afforded by the fisheries, especially for sardines, tunny, cod, and horse-mackerel. But this branch of industry has suffered by the extension of the general coasting traffic. Ayamonte is said to have had in the sixteenth century 16,000 inhabitants. Present Pop. 4675. Lat. 37. 9. N. This also is the name of a town in Portugal, in the province of Alentejo, 3 miles N.W. of Minfort.

AYEEN-AKBERY, a statistical account of the Indian Mogul empire during the reign of Akbar, by his vizier Abul-Fazi. It has been translated into English by Gladwin, and is esteemed for its accuracy.

AYLESBURY, a market and borough town of England, county of Buckingham, 39 miles N.W. of London. It stands on a gentle eminence in the centre of a fertile vale, and consists of several streets and lanes irregularly built, but well paved and lighted. The county-hall, market-house, and new county-gaol are handsome buildings, as is also the parish-church, an ancient structure with a tower rising from the centre. It has a free grammar-school, several other schools and charities, three banks, a savings-bank, and places of public worship for Roman Catholics, Methodists, Baptists, Independents, &c. It is governed by a mayor, aldermen, and councillors, and returns two members to parliament. The assizes, quarter sessions, and the elections of members for the county are held here. The inhabitants are principally employed in the manufacture of bonelace and straw plaiting, besides the rearing of ducks, which are sent in large quantities to the London market at Christmas. A branch canal six miles in length connects it with the Grand Junction Canal; and a branch railway at Cheddington connects it with the London and Birmingham line. Population of parliamentary borough in 1851, 26,794.

AYLESFORD, a village of England, county of Kent, 3½ miles from Maidstone, and 32 from London. It stands at the base of a hill on the right bank of the Medway, which is here crossed by a stone bridge of six arches. The church stands on an eminence behind the village. At a short distance to the W. was a Carmelite friary, founded in 1240, the remains of which now form a part of the family mansion of the Earl of Aylesford. The vicinity exhibits several remains of antiquity, among which is a cromlech called Keit's Coty House, about a mile N.E. from the village. It is said to mark the burial-place of Catigern, who was slain here in a battle between the Britons and Saxons in A.D. 455. Pop. of parish in 1851, 1487.

AYLMER, JOHN, bishop of London in the reign of Queen Elizabeth, was born in the year 1521 at Aylmerhall, in the parish of Tilney, in the county of Norfolk. Whilst a boy, he was distinguished for his quick parts by the Marquis of Dorset, afterwards Duke of Suffolk, who sent him to Cambridge, and made him his chaplain, and tutor to his children. One of these children was the accomplished and unfortunate Lady Jane Grey, whose extraordinary proficiency in the Greek and Latin languages reflects no small honour on her preceptor Aylmer. His first preferment was to the archdeaconry of Stow, in the diocese of Lincoln; which gave him a seat in the convocation held in the first year of Queen Mary, where he resolutely opposed the return to popery, to which the generality of the clergy were inclined. He was soon after obliged to fly his country and take shelter among the Protestants in Switzerland. While here he wrote a reply to Knox's famous *Blast against the monstrous Regiment of Women*, under the title of *An Harborowe for Faithfull and Trewe Subjects*, &c. On the accession of Queen Elizabeth he returned to England. In 1562 he obtained the archdeaconry of Lincoln, and was a member of the famous synod of that year, which reformed

Aylsham ‖ Ayr.

and settled the doctrine and discipline of the Church of England. In 1576 he was consecrated bishop of London. He died in 1594.

AYLSHAM, a market-town of England, county of Norfolk, hundred of South Erpingham, 118 miles N.N.E. of London. It stands on the River Bare, which is here navigable for boats of 13 tons. It was formerly celebrated for its linen manufacture, and more recently for its hosiery; but both these have declined, and the inhabitants are now chiefly engaged in agriculture. Pop. in 1851, 2184.

AYORA, a well-built town in the *partido* of Jarafuel and province of Valencia, in Spain. It is pleasantly situated in a hollow at the side of a mountain, which protects it from the S. and E. wind. Pop. 3785, chiefly agricultural.

AYR, a royal burgh, the capital of Ayrshire, is situated at the mouth of the river Ayr, 30 miles S.S.W. from Glasgow. The spot has been inhabited from a remote antiquity. It was the site of a Roman station; and it has been ascertained that a hamlet remained here until the year 1197, when William the Lion engrafted a new town upon it, which about the year 1202 he constituted a royal burgh. In ancient times Ayr was distinguished both for its trade and military strength; and being an important point of concentration on the W., it was the scene of frequent conflicts, and repeatedly changed hands during the wars of Scottish independence in the time of the Edwards and the Bruces. Here Edward I. fixed a powerful garrison, and here the patriotic exploits of Sir William Wallace commenced. When Scotland was overrun by Oliver Cromwell, he fixed upon it as the site of one of the four forts which he built to command the country. This fortification, termed the citadel, inclosed an area of about ten or twelve acres, including the old church where the Scottish parliament met and confirmed the title of Robert Bruce to the throne. The church was converted into a storehouse; the Protector partly indemnifying the inhabitants for this seizure by liberally contributing towards the erection of a new place of worship, which was made large enough to accommodate 2000 individuals. The town of Ayr forms a tolerably regular parallelogram, extending up the S. side of the river Ayr, which is crossed by two bridges; and it possesses several good streets and a number of elegant public and other buildings. The Ayr academy is a handsome edifice; and the town-house is considered one of the finest structures of the kind in the W. of Scotland. There are also the county buildings, which afford extensive accommodation for the circuit and provincial courts and the various local authorities. Contiguous to these stands the jail, a well-regulated establishment. In addition to the church already mentioned, there is another parish church of modern erection, besides several dissenting places of worship and a Roman Catholic chapel. The new "Wallace Tower," a Gothic structure, erected on the site of the old one, which was taken down in 1835, has, at the top, the clock and bells of the dungeon steeple. In a niche in front is a rude statue of Wallace, executed by Thom, a self-taught sculptor. The "Public Buildings" is a handsome edifice, containing assembly rooms and a reading room, and surmounted by a spire 217 feet high. Ayr possesses numerous charitable establishments, a dispensary, a mechanics' institution, an extensive subscription library, a theatre; and it also supports two weekly newspapers. There are two weekly markets and four yearly fairs. The principal manufactures of Ayr are woollen and cotton goods, carpets, shoes, &c.; the fisheries and ship-building are also carried on to a small extent. It has a considerable general trade, and imports timber and deals from America, hemp and iron from the Baltic, and provisions from Ireland. Its principal export is coal. The gross amount of customs collected at the port during 1850 was L.1835. The harbour at the mouth of the river is formed by two piers projecting a considerable way into the sea, but the bar has only a depth of about 5 feet of water at ebb tides, and not above 15 at high-water springs. On the north pier in Lat. 55. 27. N. Long. 4. 38. W. are three lights, two bright and one red, from 12 to 35 feet above high water. In 1849, 49 vessels (of 6483 tons) belonged to the port. Ayr is connected by railway with Glasgow, Kilmarnock, &c. It unites with Campbeltown, Inverary, Irvine, and Oban, in returning a member to parliament. In 1851 the municipality of Ayr contained 9115 inhabitants; the parliamentary burgh 17,624, consisting of part of the parish of Ayr (7894), of Newton-upon-Ayr (4470), and of St Quivox (5260). Alloway Kirk, and Burns' Monument, are within 2½ miles of Ayr.

Ayr ‖ Ayrshire.

AYR, NEWTON UPON. While the town of Ayr extends along the S. side of the river Ayr, this small parish is situated on the N. side of the same river. It is a burgh of considerable consequence, having a baronial jurisdiction, and is governed by a magistracy elected by freemen, and (since 1832) is comprehended within the parliamentary burgh of Ayr. It is of very ancient erection, owing its privileges to Robert Bruce; who, upon being attacked by leprosy, came to reside in this place, and was induced to establish a lazarhouse, and to confer considerable favours on the town, and on the small village of Priestwick, about two or three miles distant. In Newton-upon-Ayr are a number of very good houses. From its situation on the banks of the Ayr and the sea-coast, the soil is mostly flat and sandy. Its extent is about three miles in length and one-and-a-half in breadth. Pop. in 1851, 4814.

AYR, a river in Ayrshire, which takes its rise in the high grounds dividing the shire on the E. from Lanarkshire, and pursuing a westerly course for 18 miles, falls into the sea at the town to which it gives name. The volume of its waters is not large, but it sometimes shifts its bed, and does considerable damage. It contains those whetstones called Water-of-Ayr stones, which are exported in considerable quantities.

AYRSHIRE, a county in the W. of Scotland, considerable for its population and industry, is bounded by Wigtonshire and the stewartry of Kirkcudbright on the S., by the counties of Dumfries and Lanark on the N.E. and E. by Renfrewshire on the N., and by the Irish Sea and the Firth of Clyde for about 70 miles on the W. It contains 1015 square miles, or 650,156 statute acres. The middle part of the county, where it is broadest, is about 25 miles across. The high ridgy land which stretches along its eastern boundary shuts it out, in a general sense, from the adjacent counties, and the surface inclines either to the sea or to the rivers which flow towards it. Ayrshire possesses only six rivers of note, Ayr, Stinchar, Girvan, Doon, Irvine, and Garnock; but the streams are very numerous, and fresh-water lakes abound, of which the most extensive is Loch Doon, the parent of the river of that name. None of the mountains are deserving of particular notice. In former times the shire was divided into three districts; Carrick lying on the southern side of the Doon; Kyle, lying between the rivers Doon and Irvine; and Cunningham, comprehending the whole of the county N. of the river Irvine. These divisions, although abolished by the statute, still continue to be recognized in statistical descriptions of the county. Carrick is a hilly, wild region, and only of value in its northern quarter. It contains nine parishes, and comprises 380 square miles. Kyle possesses much valuable land towards the coast, but the interior is rough and mountainous; it contains 21 parishes, with a superficies of 395 square miles. But the most fertile part of the county is Cunningham, which is comparatively level, comprising 240 square miles, and 16 parishes. The valued rent is L.191,605, 0s. 7d. Scots, and in 1843 the annual value of houses and land was L.520,828 sterling. It returns a member to parliament. The advantages possessed

Ayrshire. by Ayrshire, besides its sea-coast and several excellent harbours, may be traced to the great abundance of coal and limestone found in almost every part of it,—the one so necessary to its manufactures, and the other to its agriculture; and the chief natural disadvantage under which it labours is the humidity of its climate, aggravated by the quality of a considerable part of the soil, which is a tenacious clay.

Agriculture. Agriculture, according to the more approved courses of management, has nevertheless made considerable progress of late in this county. Somewhat more than half a century ago, the greater part of it consisted of moss and moorlands, or of an unproductive clay or sandy soil. Since then great advances have been made, particularly within the last 10 or 15 years. One-half of the country is now under cultivation; improved rotations have been introduced, and draining has been carried on to a great extent, by means of which, as well as by being mixed with lime and other manure, much of the clay soil has been turned into a rich and productive mould; and now oats, wheat, barley, pease, beans, potatoes, and other agricultural produce are extensively raised. The dairy is, however, the chief object of attention to the Ayrshire husbandmen, and their valuable breed of cows, and rich yet mild cheese known by the name of Dunlop cheese, are in great repute. Their horses, under the general name of Clydesdale or Lanarkshire horses, are highly valued; almost every small farmer either rearing one or more himself, or purchasing them when young, and selling them to the eastern counties after a year or two of very moderate labour.

Manufactures. Ayrshire, as a manufacturing district, seems to stand next in importance among the Scottish counties to the contiguous shires of Lanark and Renfrew. Various branches of the woollen manufacture are carried on to a considerable extent in Kilmarnock, and other places, and extensive cotton works have been established at Catrine. Muslin, shawls, carpets, cloth, flax, linen, and silk goods, nails, leather, saddlery, and earthenware, are among its manufactures.

Minerals. Within these few years Ayrshire has become one of the most important counties of Scotland by the development of its mineral traffic. In the hands of persons of great capital and enterprize immense fields of ironstone are being worked at Dalry, Kilbirnie, New Cumnock, and Dalmellington; while coal, generally of good quality, is exceedingly abundant in the districts of Kyle and Cunningham. The coal and iron are extensively shipped at the ports of Troon and Ayr. There are coal-mines at Dalry, Kilwinning, Galston, Muirkirk, St Quivox, Coylton, and Riccarton; at Muirkirk, Glenbuck, and other places iron founderies have been erected; tiles are made of the clay for draining and other purposes; and millstones are quarried at Kilbride. On the property of the Honourable Colonel Macadam Cathcart, of Craigengillan, at Carsphairn, on the borders of Kirkcudbrightshire, lead mines have been for a period of years in operation, but without yielding large returns. The hills consist chiefly of granite, with whinstone, greenstone, red sandstone, &c.; and lime and whetstones abound.

Commerce. Ayr, Irvine, and Saltcoats, were, till very lately, the only harbours much frequented; and at these places there has long been a little trade with Ireland, America, and the Baltic, and a considerable coasting trade. Coal is the staple article of export, and corn the most considerable of its imports: the ports on the Clyde having hitherto been the grand emporium of the W. of Scotland.

Among the antiquities of Ayrshire are the cairns at Galston and Lorn; camps, supposed to be Danish, at Dundonald and on the hill of Knockgeorgan near Ardrossan; the castles of Loch Doon, Turnberry, Dundonald, Portincross, &c.; the abbeys of Crossraguel, and Kilwinning; and the kirk of Alloway, immortalized by Burns in his "Tam o' Shanter."

This county exhibits striking examples of public spirit in its great landed proprietors. The harbour and other works at Ardrossan, begun under the auspices of the late Earl of Eglinton, the harbour of Troon, and the railway from thence to Kilmarnock, formed almost entirely at the expense of the Duke of Portland, are monuments, no less of the energy and enterprizing spirit than of the wealth of these noblemen. Ayrshire || Ayscue.

Ardrossan harbour. The harbour of Ardrossan has been for many years in a state to receive shipping, and is considered as one of the safest, most capacious, and most accessible on the W. coast of Scotland; possessing many advantages over the harbours in the Firth of Clyde, situate in a narrow channel, which can be navigated only when the wind blows from particular points, and which, for upwards of 20 miles below Glasgow, is both shallow and dangerous. A circular pier of 900 yards was finished in 1811; and the wet dock and other appendages, which, according to Mr Telford's plan, were to contain from 70 to 100 vessels, in water 16 feet deep, were begun and nearly completed, when the death of the late Earl of Eglinton in 1820 brought them to a stand. They have now been completed by the present Earl. Excellent baths have been constructed, which draw to it a number of visitors during the summer season; and there is one expressly for the use of the poor, for which no charge is made. The harbour of Ardrossan was only part of the general plan, and that from which, viewed by itself, the smallest advantages perhaps were to be expected. The leading idea was to open up a direct communication between Glasgow, Paisley, and other large towns in the vicinity, and the W. coast, instead of the present circuitous passage by the Firth of Clyde. A canal was therefore to be cut from Glasgow to Ardrossan, about 31½ miles, at the estimated expense of L.125,000. Of this only a third has been executed, that is, from Glasgow to Johnstone, which cost about L.90,000, the canal having been superseded by the Glasgow and Ayr Railway. Canal.

Troon harbour. The harbour at Troon, connected as it now is with Kilmarnock by means of a railway, seems to possess the same advantages as that of Ardrossan. The wet and dry docks are excellent, and are well employed. There are also extensive warehouses, and a yard for building vessels. The railway from Troon to Kilmarnock, a distance of 10 miles, has been in operation for many years, and answers all the purposes for which it was originally intended. There are upwards of 3000 acres of coal fields in its course, which must in time indemnify the Duke of Portland for his outlay both on this and the harbour. This railway has cost the duke upwards of L.50,000, and the harbour is estimated at about the same sum. The Glasgow and Ayr Railway was opened in 1840, and is 40 miles in length; a branch of which goes from near Dalry to Kilmarnock, and another from near Kilwinning to Ardrossan. The Glasgow, Dumfries, and Carlisle Railway passes Kilmarnock, and sends off a branch to Muirkirk. A line from Ayr to Dalmellington is in progress. Railway

Population. The following abstract will exhibit a view of the population of Ayrshire in 1851:—

1851.						
Districts.	Houses.			Inhabitants.		
	Inhabited.	Uninhabited.	Building.	Male.	Female.	Total.
Carrick	4,575	128	15	15,455	15,847	31,302
Kyle	9,455	363	57	35,394	36,890	72,284
Cunningham	9,524	333	57	42,081	44,191	86,272

AYRY, or Aery, a nest or company of eagles or hawks, so called from the old French word *aire*.

AYSCUE, Sir George, a gallant English admiral, descended from a good family in Lincolnshire. He obtained the honour of knighthood from Charles I., but adhered to the parliament in the civil war. He was by them appointed admiral of the Irish seas, where he did great service to the

Ayton ‖ Azerbijan.

Protestant interest. In 1651 he reduced to the obedience of the parliament Barbadoes and Virginia, which then held out for the king; and after the Restoration he behaved with much gallantry in the war with the Dutch. In the famous engagement in the beginning of June 1666, when Sir George was admiral of the white squadron, his ship, the Royal Prince, ran upon the Galoper-sand, where, being surrounded with enemies, his men obliged him to strike. He went no more to sea after this, but spent the rest of his days in retirement.

AYTON, Sir Robert (1570–1638), a Scottish lyrical poet, was the son of Ayton of Kinaldie in Fifeshire. He was knighted by James VI., and held various important offices at court. Like his contemporary Drummond of Hawthornden, he had the advantage of foreign travel and acquaintance with English poets, among others with Ben Jonson. That great man seemed proud of the friendship, for he told Drummond that Sir Robert loved him dearly. Ayton wrote but little, and that little was in the English dialect. The smoothness of his rhythm, and the delicacy of his fancy, give an exquisite charm to the few pieces of his that have come down to us. His odes *On Woman's Inconstancy*, and *I do confess thou'rt smooth and fair*, may take rank with the finest pieces of Herrick or Suckling.

Ayton, a village and parish of Scotland, county of Berwick, on the River Eye. Pop. of parish in 1851, 1959. It is 7½ miles N.W. of Berwick.

AZAMOR, a small seaport town in the kingdom of Marocco, in the province of Dukalla. It is situated in a very fruitful district, near the mouth of the River Morbeya. Long. 8. 15. W., Lat. 33. 17. 37. N. Pop. 3000.

AZARIAH, or Uzziah, ninth king of Judah, succeeded his father Amaziah 810 years B.C. He assembled an army of above 300,000 men, with which he conquered the Philistines, demolishing the walls of Gath, Jabniel, and Ashdod, and built up the walls of Jerusalem, furnished the city with conduits, and planted gardens and vineyards; but at last, being elated with his prosperity, and resolving to usurp the office of high-priest, he was struck with leprosy, which obliged him to remain shut up in his palace for the rest of his days. He died about 757 years before the Christian era, and was succeeded by Jotham his son. (2 Kings; 2 Chron.) There are twelve other persons of this name mentioned in the Sacred Scriptures.

AZERBIJAN, a province of Persia, part of the ancient Media. It is separated from Armenia on the N. by the River Araxes; and from Irak on the S. by the Kizil-Ozein, or Golden Stream. It has the Caspian Sea and Ghilan on the E., and Armenia and Kurdistan on the W. The country is superior to the southern provinces of Persia, being richly diversified with wood and water. It differs entirely from the provinces of Fars and Irak, as it consists of a regular succession of undulating eminences, partially cultivated, and opening into extensive plains such as Anjan, Tabreez, and Urumea or Van. Near the centre of the province the mountains of Sahend rise in an accumulated mass to the height of 9000 feet above the sea. Mount Sevellan, towards its eastern frontier, attains a height of nearly 13,000 feet; and the Talish Mountains, which run from N. to S., parallel to and at no great distance from the Caspian, attain an altitude of 7000 feet. Azerbijan is a fertile country, and of a most pleasing aspect. It is reckoned one of the most productive provinces of Persia, and the villages have a more pleasing appearance than those of Irak. The orchards and gardens, in which they are for the most part embosomed, yield delicious fruits of almost every description. Provisions are cheap and abundant, and wine is made in considerable quantities. This province is watered by several considerable rivers, namely, the Araxes, the Kizil-Ozein, and the Juggaty. The Yezdican and the Harasa are tributaries of the Araxes; and the Agi and Shar flow into the lake of Urumea. This lake is about 300 miles in circumference. Its waters are more intensely salt than the sea. It is surrounded by some of the most fertile districts in Persia. The country to the N. and W., namely, the districts of Urumea and Selmart, is the most picturesque and prosperous part of Azerbijan; yet even here the traveller from the more civilized regions of Europe laments at every step the sloth and want of enterprize among the inhabitants, who entirely neglect the natural advantages of their country. There are many rivers which fall into the lake, by which the produce of the rich and well-cultivated valleys through which they run might be transported across its waters, and dispersed among the different towns in the province. The truth, however, is, that individual exertion is damped by the tyranny of the government; the inhabitants fearing that, if boats were constructed for the navigation of the lake, they would be subjected to heavy duties, or arbitrarily impressed into the service of government. The bulk of the people are so held down by their rulers, that, in the hope of bettering their condition, they would hail with pleasure the approach of a Russian army. Lead, copper, saltpetre, and sulphur, are found within the confines of Azerbijan; also a kind of beautiful transparent marble or jasper, which takes the highest polish, and is used in the buildings of Tabreez, Schiraz, and Ispahan, under the name of Tabreez marble. The chief towns are Tabreez, Urumea, Ardebil, and Khoee. The climate is healthful—in summer and autumn hot, but cold in winter, which is severely felt by the lower orders, owing to the want of fuel, for which there is no substitute except dried cow-dung, mixed with straw. The spring is temperate and delightful in the plains, but on the mountains snow lies eight months in the year; and hail-storms are so violent as frequently to destroy cattle in the fields. The best soils yield from fifty to sixty fold when abundantly irrigated; and supplies of water for this purpose are drawn from the many small rivers by which the province is intersected. Oxen are generally used to draw the plough. (Kinneir's *Geographical Memoir of the Persian Empire*; Fraser's *Travels and Adventures in the Persian Provinces on the Caspian Sea.*) (D. B—N.)

Azimuth ‖ Azoph.

AZIMUTH, in *Astronomy*, an arch of the horizon intercepted between the meridian of the place and the vertical circle passing through the centre of the object.

Azimuth, Magnetical, an arch of the horizon, intercepted between the vertical circle passing through the centre of any heavenly body and the magnetical meridian.

Azimuth Compass, an instrument for finding either the magnetical azimuth or amplitude of a heavenly object.

Azimuth Circles, called also *azimuths* or *vertical circles*, are great circles of the sphere intersecting each other in the zenith and nadir, and cutting the horizon at right angles. On these are reckoned the height of the stars and that of the sun when not in the meridian.

AZOGA Ships (from the Spanish *azogue, mercury*), vessels which carried quicksilver to the Spanish West Indies, in order to extract the silver from the mines of Mexico and Peru. They carried no goods except for the king.

AZOPH, or Asow, a city on the left bank of one of the arms of the Don, about 20 miles from its mouth. It was formerly a place of great importance, but has declined since 1774, when it became a fixed part of the Russian empire. The harbour is nearly choked up, and the fortifications are neglected. Pop. 1200. The country around, although unhealthy, is fruitful in vines. Long. 39. 8. E. Lat. 47. 6. N.

Azoph, *Sea of* (the *Palus Mæotis* of the ancients), an inland sea of Southern Europe, communicating with the Black Sea by means of the Strait of Yenikalé, the ancient *Bosphorus Cimmerius*. It lies between Lat. 45. 20. and 47. 18. N. and Long. 35. and 39. E.; its length from S.W. to N.E. being about 235 miles, and its greatest breadth 110 miles. The rivers Don, Kuban, Kalmius, and Breda, enter this sea, rendering its waters much less salt than the ocean; and in-

Azores. deed they are little more than brackish. Near its coast are the towns of Taganrog, Mariupol, Yenikalé, Azoph, and Berdiansk, which last has risen since 1835, from a mere village, to be the most important commercial town on this coast. Polybius affirmed that this sea was gradually filling up, so that at no remote period it would be unfit for navigation; and since his time the common opinion has been, that it was decreasing in depth; but recent observations have proved this idea to be erroneous. (Jones' *Travels*, vol. ii. p. 145.) Near the mouth of the Don the water is exceedingly shallow, being only from three to ten feet, according to the direction of the wind; but otherwise it varies from 42 feet in the centre, to an average of about 18 feet close to the shore. The Strait of Yenikalé has at all times a depth of at least 14 feet; and vessels of a greater draught may find secure anchorage where they can discharge their cargoes. The shipping season extends from about the middle of April to the end of November, and the sea is generally frozen from December to March. The fisheries here are very important.

AZORES, or Western Islands. These form a range situate in the Atlantic Ocean, extending in an oblique line from N.W. to S.E., between 37° and 40° N. Lat., and 25° and 32° W. Long. It has been a subject of some controversy among geographers, to what division of the globe they ought to be referred; but they are now generally considered as pertaining to Europe.

It does not appear that the ancients had any knowledge of the Azores, or of any group in this sea, except the Canaries, to which they finally applied the celebrated appellation of the Fortunate Islands. But the Arabian geographers, Edrisi and Ibn al Vardi, describe, after the Canaries, nine other islands in the Western Ocean. That these were the Azores is highly probable, since their number is exactly nine; and because a species of hawk is specially noticed by these writers as existing there in great abundance,—a circumstance that afterwards appeared to the Portuguese so remarkable, that they gave them the name of Azores, or Hawk Islands. The climate in which they are placed also makes them north of the Canaries. Some other coincidences also might be pointed out; and, upon the whole, there appears no reason to doubt that the Azores are really the nine islands enumerated by the Arabians. The Arabian writers represent them as having been populous, and as having contained cities of some magnitude; but they state that the inhabitants had been greatly reduced by intestine warfare. At the time of their discovery, they were uninhabited, and covered with forests and underwood, which have now entirely disappeared.

History. The first European discovery of this group is claimed by the Flemings. A Flemish merchant named Van der Berg, is reported, in sailing from Lisbon, to have been driven upon these shores in the year 1439. The intelligence soon reached the court of Lisbon, where it excited considerable interest; and the navigator Cabral was sent to prosecute the discovery. In 1459 the islands began to be planted and colonized, and in so fertile a soil the inhabitants rapidly multiplied. In 1580 they fell, with the other Portuguese territories, under the dominion of Spain. At this time the Azores were the grand rendezvous in the voyage homewards of the fleets, which came laden with the wealth of both the Indies. Hence they became a theatre of that maritime warfare which was carried on with such spirit by the English under Queen Elizabeth against the peninsular powers. In 1586 Sir Walter Raleigh equipped two pinnaces of 35 and 40 tons, the command of which he gave to Captain Whiddon. Having taken two or three prizes, they fell in, off St Michael, with the great fleet of Spanish galleons, consisting of 24 sail, two of them caracks of 1000 or 1200 tons. They attacked them, however, without hesitation, hoping to cut off some straggling member of this great body, but were unable to make any impression upon it. In 1587 Sir Francis Drake, after having swept the harbour of Cadiz, sailed for the Azores, where he took an East India carack, richly laden, and the first that had ever fallen into the hands of the English. In 1589 the Earl of Cumberland fitted out a squadron, sailed for the Azores, and made numerous prizes. Azores.

Under the active administration of Pombal, considerable exertions were made for the improvement of the Azores; but the stupid and bigoted government which followed rather tended to destroy these benefits, and to make the islands take a retrograde course.

The Azores within a recent period attracted some attention as the theatre of contest between the parties contending for the crown of Portugal. The adherents of the constitution, who supported against Miguel the rights of Maria da Gloria, obtained possession of Terceira, where they succeeded in maintaining themselves. After various struggles, Queen Maria's authority was eventually established over all these islands.

The aspect of all the islands is very similar in general characteristics, presenting an elevated and undulating outline, with little or no table-land, and rising into peaks, of which the lowest (that of St Mary's) is 1889 feet, and the highest (that of Pico) 7613 feet above the level of the sea. Their lines of sea-coast are with few exceptions high and precipitous, with bases of accumulated masses of fallen rock, in which open bays, or scarcely more inclosed inlets, form the harbours of the trading towns. The climate is particularly temperate and equable, the extremes of sensible heat and cold being, however, increased by the degree of humidity present in the atmosphere. The range of the thermometer is from 45° Fahr., the lowest known extreme,—or 48° the ordinary lowest extreme of January,—to 82° the ordinary, or 86° the highest known extreme of July, and near the level of the sea. Between these two points (both taken in the shade) there is from month to month a pretty regular gradation of increase or decrease, amounting to somewhat less than four degrees (*Geographical Journal*, vol. xv.) They have an aggregate area of 700 square miles, and in 1841 had a population of 214,300. St Michael, the largest and most populous of these islands, has an area of 224 square miles, and (1840) 80,809 inhabitants. Proceeding from E. to W., this island presents a considerable variety of surface. The E. end rises from a bluff sea-cliff of between 1200 and 1400 feet elevation, to a lofty inland peak from which a central range, varying in height from 2000 to 2500 feet, runs to the westward, terminating in the Serra da Agoa de Pao, 3060 feet above the sea. The sea-coast gradually declines in approaching the last point, where it is not more than about 100 feet high. The part next seen is lower, and its outline, as presented by the summits of numerous volcanic monticules of about 1300 feet elevation, united in a central ridge more undulating; the western extremity being marked by the conspicuous Serra Gorda, 1574 feet above the sea; and its shores on both sides are low, broken, and rocky. Of the remaining part the aspect is that of a vast truncated cone, irregularly cut off at an elevation of about 800 feet, and falling on the N., S., and W. sides to a perpendicular coast of between 300 and 800 feet high. The outline is varied by the intervention of peaks, thrown up on the summit and flanks, and round the foot of the mountain. In the higher parts, the surface is generally covered with an undergrowth of heaths, cedar, laurel, laurestinus, and other evergreen shrubs, which give the mountains an exceedingly rich and wooded appearance. Like all volcanic countries, the face of the island is uneven and irregular, being deeply excavated by numerous ravines and roughened by streams of semi-vitrified and scoriaceous lava that resist all atmospheric influences and repel vegetation. Heavy rains falling on the mountains afford a constant supply of water to four lakes at the bottom of extinct craters or subsidences, and a number of minor reservoirs; and through them to small streams running rapidly down on all sides into the sea.—(*Geographical Journal*, vol. xv.) Physical aspect.

Azores.

Volcanic phenomena.

In the year 1591 a most tremendous earthquake appears to have been felt all over the Azores, and to have shaken St Michael for twelve days without intermission. Since that period there is no record of any such great convulsion, except one in 1757, of which we have no particulars, and it was probably much less formidable; nor are any of its volcanoes at present in a state of action. Hot springs abound in every part of the island, and from almost every crevice vapour is seen issuing. But the most remarkable phenomena are the Caldeiras or boiling fountains, which rise chiefly from a valley called the Furnas, near the western extremity of the island. The water ascends in columns to the height of about 12 feet, after which it dissolves in vapour, forming clouds of various shapes and colours. The heat is such as to boil an egg in two minutes, though the sulphurous impregnation unfits it for being employed in culinary purposes. The ground in the immediate vicinity is entirely covered with native sulphur, like hoar frost. At a small distance is a remarkable phenomenon called the Muddy Crater, the vertex of which, 45 feet in diameter, is on a level with the plain. Its contents are in a state of violent and continual ebullition, accompanied with a sound resembling the waves of a tempestuous ocean. Yet they never rise above its level, unless occasionally to throw to a small distance a spray of the consistence of melted lead. The Furnas abounds also in hot springs, some of which it is impossible to touch without being scalded. There is almost always, however, a cold spring near to the hot one, so that the water can be brought to any temperature that may be desired. These springs, after being long neglected, have, within the last half century, been greatly resorted to, and the cures performed in cases of palsy, rheumatism, and similar maladies, are said to have been very wonderful.

Vegetable products.

The plains are fertile in wheat, barley, and Indian corn; whilst vines and oranges grow luxuriantly on the sides of the mountains. They are made to spring even from the interstices of the volcanic rocks, which are sometimes blasted in order that they may receive the plants. Raised in this manner, these fruits are said to be of superior quality; but the great expense originally required in such a mode of cultivation confines it to persons of some capital. The western part of the island yields hemp, which might be raised to a considerable extent. The exports consist of wine, fruit, and provisions. Foreign intercourse used to be confined rigorously to Lisbon; but since the emigration of the court, the inhabitants have assumed the privilege of trading directly with England, America, and other countries.

The principal town in the island is Ponta Delgada, which contains about 20,000 inhabitants. It is built with tolerable regularity, the streets being straight and broad. The religious edifices are numerous and elegant. When visited by Captain Boid in 1831, it had six churches, eight monasteries, and four convents; but these last, which were noted for the irregular lives of their vestals, have since been suppressed. The harbour receives only small vessels: those of any magnitude must anchor in an open road, which, though not dangerous, cannot be occupied during the prevalence of southerly gales. Its other towns are Villa Franca, Ribeira, Grande, Alagoa, Agoa de Pao, &c.

St Mary.

St Mary is a small island immediately adjacent to St Michael, through the medium of which its trade is conducted, as it has no good harbours of its own. It has an area of 36 square miles, producing wheat in abundance, of which a considerable quantity is exported. It is of trap formation, and contains beds of marine shells. Pop. in 1840, 4666.

Terceira.

Terceira, though smaller than St Michael, yet being placed in a more central position with respect to the other islands, has been chosen as the seat of government. The port of Angra is also superior to any of those in St Michael. This island does not exhibit nearly the same extensive traces of volcanic action; and the summits of its mountains are generally level. It is represented by Adanson, however, as entirely composed of volcanic products. The lava, he says, is of a thicker grain than that of Teneriffe. It abounds in grain and cattle; but the wines are inferior, and the fruits are raised merely for internal consumption. The residence of the government renders the society somewhat superior to that which is found in the other islands. The number of inhabitants is estimated at 50,000.

Azores.

Fayal.

Fayal is the most frequented of all the islands after St Michael, as it has one of the best harbours in the Azores, and lies directly in the track of vessels that are crossing the Atlantic in any direction. Its principal town is Villa de Horta. Captain Cook found that all sorts of fresh provisions might be obtained there: the bullocks and hogs are good, but the sheep small and poor. The town is defended by two castles and a wall, both in decay, and serving rather for show than strength. The city contains two convents for monks and three for nuns, with eight churches. These are the only good buildings in it, no other having glass windows. The bay is two miles in length and three-quarters of a mile in breadth, and the depth of water from 6 to 20 fathoms. Though a good road, it is not altogether free from danger in S.S.W. and S.E. winds. Pop. 23,000.

Pico.

A considerable quantity of wine is exported from Fayal under the appellation of Fayal wine, but really the produce of Pico, one of the most remarkable of the Azores. This island is composed of an immense conical mountain, rising to the height of 7613 feet, and bearing every trace of volcanic formation. The soil consists entirely of pulverized lava, and the ground has even been said to sound hollow when struck. All the lower parts of the mountain are in the highest state of cultivation, and covered with vine and orange plantations. The wine, which forms a sort of inferior Madeira, is in considerable demand. Pico produces also a valuable species of wood, resembling and equal in quality to mahogany. Pop. 26,000.

Graciosa and St George.

Graciosa and St George are two small islands, situated between Fayal and Terceira. Graciosa is chiefly noted for the extreme beauty of its aspect and scenery. About 50 years ago St George suffered from one of those awful visitations to which the Azores are subject. In 1808 a caldeira, situate in the centre of the island, was observed to be in a state of violent fermentation. It continued during several days to emit subterraneous noises, and to cause violent convulsions throughout every part of the island. At length the great crisis came; vast streams of fire issued forth in every direction, with clouds of smoke, which, but for the volcanic light, would have involved everything in midnight darkness. The principal stream took its direction towards the beautiful town of Ursula, which it seemed on the point of swallowing up; but suddenly changing its direction, it rushed into the sea by a different channel; a happy event, which superstition ascribed to the prayers of the Ursuline nuns. Many hundred acres of fertile land, however, were covered with scoriæ and ashes; some lives were lost, and general gloom and consternation diffused throughout the island. The inhabitants, however, soon applied themselves to repair the injury which their land had sustained. Population about 20,000.

Corvo and Flores.

The two small and most westerly islands of Corvo and Flores seem but imperfectly to belong to the group. They lie also out of the usual track of navigators; but to those who, missing their course, are led thither, Flores affords good shelter in its numerous bays. Its poultry is said to be the finest in the world; and the cattle are numerous, but small. The surplus produce of these islands is not of much importance. Population above 15,000.

It would be improper to close this notice without mentioning one of the most striking occurrences in nature, sometimes exhibited in this quarter—the sudden emersion of new islands from the bosom of the ocean. The first relation of

Azote ‖ Azpeitia.

such an event is given by Kircher in his *Mundus Subterraneus*. He describes it as announced by violent earthquakes, which lasted for eight days; then a fire broke from the surface of the sea, and rose to the clouds, whilst vast quantities of stones, earth, sand, and minerals, were at the same time vomited out. At length a group of rocks burst forth, which gradually increased till they covered several miles in circumference, and, after being shattered by a new earthquake, settled into a solid consistence.

A narrative of a similar phenomenon is given in the 32d volume of the *Philosophical Transactions*. John Robison, master of a small vessel, is stated to have arrived on the 10th December 1720 at Terceira, "near which island he saw a fire break out of the sea." On his arrival at Angra, the governor hired his vessel for the purpose of going to view it. "On the 19th," says he, "at two afternoon, we made an island all fire and smoke. The ashes fell on our deck like hail and snow. The fire and smoke roared like thunder or great guns." He adds, that quantities of pumice stone, probably common lava, and of half-broiled fish, were found floating on the sea in its vicinity.

A similar phenomenon took place in June 1811, about half a league from the western extremity of the island of St Michael. On the 13th of that month an island was thrown up in the sea, to which was given the name of Sabrina, by the commander of the British man-of-war of that name, who witnessed the explosion. It was soon worn away by the sea, and is now only to be traced in a submarine cone 15 fathoms under the surface.

See Hartmann's *Edrisi; Voyages des Hollandois*, tome i.; Astley's *Collection*, vol. i.; Masson's Account of St Miguel, in *Phil. Trans.* 1778; Cook's *Second Voyage*; Adanson's *Voyage to Senegal; History of the Azores*, London, 1813; Boid's *Azores; London Geographical Journal.*

AZOTE (*α*, priv., and *ζωή, life*), one of the gases. See CHEMISTRY.

AZOTUS, or ASHDOD (now ESDUD), a city of Palestine, near the sea-coast, 10 miles N.N.E. of Askelon. It was the chief town of one of the five states of the Philistines, and the seat of the worship of Dagon. Although assigned to the tribe of Judah, it was many centuries before it was subdued, and it appears never to have permanently been in their possession. The site is marked by ancient ruins, such as broken arches and fragments of marble columns. There is also what appears to be a very ancient khan, the principal chamber of which had obviously at some former period been used as a Christian chapel.

AZPEITIA, a Spanish town in the province of Guipuzcoa, on the left bank of the River Urola, on the N. side of Mount Itzarritz. The neighbouring country is fertile, and quarries of marble are wrought in the mountains. Pop. 5300.

Aztecs ‖ Azzara.

AZTECS, the native name of the nation that last occupied the table-land of Mexico before the arrival of the Spaniards in America. They came from a country in the N.W. of that continent, to which they gave the name of Aztlan, about the year 1160 of our era; and they settled at first on the banks of the Rio Gila. They gradually increased their influence among other tribes, until, by union with the Toltecs, who occupied the table-land before them, they extended their empire to an area of from 18,000 to 20,000 square leagues. The researches of Humboldt afforded us the first clear insight into those early periods of their history. See MEXICO.

AZUNI, DOMENICO ALBERTO, a celebrated jurisconsult, born at Sassari, in Sardinia, in 1760, and author of an esteemed work on *The Maritime Law of Europe*. He died in Sardinia in 1827.

AZURE. See HERALDRY.

AZZARA, DON FELIX DE, a celebrated Spanish naturalist, was born 18th May 1746. He studied first at the university of Huesca, and afterwards at the military academy of Barcelona. In 1764 he entered the army as a cadet, and in 1767 obtained an ensigncy in the engineer corps. In 1781 he was appointed, with the rank of captain in the navy, on a commission to lay down the line of demarcation between the Spanish and the Portuguese territories in South America. There he spent many years, observing and collecting specimens of the various interesting objects of natural history that abound in those wide and little known regions. In 1801 he obtained leave to return to Spain, and was afterwards appointed a member of the *Junta de fortificaçiones y defensa de Ambos Indias*, a public board in which chiefly was centred the home government of the Spanish colonies. He died in 1811. His principal work is his *Travels in South America from* 1781 *to* 1801; published in French from the author's MS., by C. A. Walckenaer. with atlas and plates, 4 vols. 8vo, Paris, 1809. It contains a valuable account of the discovery, conquest, civil and natural history of Paraguay and Rio de la Plata; and embodies his former contributions to the zoology of these countries. The work is enriched with the notes of Walckenaer and Cuvier, and a notice of the author by the former.

AZZARA, *Don Jose Nicolas de*, the elder brother of the naturalist, was an eminent collector of Italian antiquities; and withdrew to Florence when the French took possession of Rome in 1798. He was afterwards Spanish ambassador at Paris, but was displaced by Godoy, and was preparing to return to his antiquarian studies in Italy in 1808, when he died. His best claim to notice is the active part he took, as a minister under Val, in the difficult and hazardous task of the expulsion of the Jesuits from Spain. He died at Paris in 1804.

B.

P. B, the second letter, and first consonant, in all known alphabets excepting the Ethiopic, where it occupies the ninth place. It is a labial and mute, representing the compression of the lips, and consequently incapable of being uttered or pronounced without the aid of a vowel, or a forcible expiration equivalent in effect to vocality. This letter has a near affinity to the other labials, with which, indeed, it is interchangeable according as the compression of the lips, which it primarily indicates, is modified by simultaneous expiration; and hence, although its ordinary power or effect is intermediate between the smooth and easy sound of P, and the rough aspirations of PH, F, and V, yet, in the articulation of many languages, it is habitually confounded with one or other of the letters of the same class, and in the same language at different times, is frequently interchanged with its cognate consonants. Thus, *βόσκω* in Greek becomes *pasco* in Latin; *γίλβος, gilvus; βρέμω, fremo; πύξος, buxus; ἄμφω, ambo; φάλαινα, balæna; θρίαμβος, triumphus*; and so in many other instances. Again, in Latin, the B of the olden time, and of the inscriptions, passes into V in a subsequent age; while, on the other hand, the P of the antique orthography is commuted into B in that of a more recent date. Hence we have *abavus* for *ababus, ave* for *abe, vixit* for *bixit, curvatus* for *curbatus*, and hundreds of other analogous instances; while *Poplius* for *Publius, Poplicus* for *Publicus, Poplicola* for *Publicola*, are of frequent occurrence in the inscriptions and other elder monuments of the Latin language. This letter is also sometimes inserted in the middle of compound words for the sake of euphony, and to prevent the *hiatus* which would otherwise result from the concurrence of vowels, as *ambages, ambio, amburo;* it is servile in the dative and ablative plural of the third, fourth, and fifth declensions of Latin nouns, and in the præterimperfect and future tenses of the first and second conjugations; and it is interchangeable with P, F, and other letters, both in the composition and conjugation of a number of verbs. In Hebrew, the name of the second letter בֵּית, *bith* or *beth*, indicates the original hieroglyph to have represented a house or temple; whilst an abbreviated form of the figure has been employed to denote the initial sound of the word in the spoken language; a principle, also, upon which the ancient Egyptians appear to have constructed their phonetic alphabet, or used the symbolical characters of their complex system of writing for representing the constituent sounds of proper names and of legends. A difference, however, will be observed between the two Phœnician forms of this letter, the first of which is that of a house or temple, whilst in the second another figure seems to have been combined with the first; from which it is probable that this people, the inventors of alphabetical characters or signs, had originally two hieroglyphs for the letter, and consequently two words by which it was named. This compound hieroglyph seems to have been composed of the *beth* or house, and of the head and horns of some animal placed over it, perhaps those of a בּוֹקֵר, *boker*, ox or wild goat; which would explain the assertion of Hesiod, that the second or third letter of the Phœnicians was represented by an ox. At all events the Phœnician, reproduced in the early Greek, has served as the basis of most modern varieties in the languages of the West; and, amidst every change which time, accident, or caprice, has superinduced, it is still easy to detect and distinguish the elementary or primitive form. With regard to the different sounds or powers attached to the letter in modern languages, these have varied within the limits of its natural affinity; the Germans giving it the effect of P, the Spaniards, Gascons, and others, that of V; and the modern Greeks sometimes that of V, but more frequently sounding it as we do F. The satirical epigrammatist who affirmed that in Gascony *bibere* is the same as *vivere*, stated a literal truth, in as far at least as the pronunciation of the words is concerned. (J. B—E.)

Baal ‖ Baalbec.

BAAL, the same as BEL or BELUS, an idol of the Chaldeans and Phœnicians or Canaanites. The word *Baal*, in the Punic language as well as in the Hebrew, signifies "lord" or "master," and doubtless meant the supreme Deity; yet there is no evidence that the Israelites ever called Jehovah by the name of Baal; for the passage in Hosea ii. 16, which has been cited as such, only contains the word *baal* as the sterner, less affectionate, representative of *husband*. Some learned men identify the Baal of the Phœnicians with the Saturn of the Greeks; others with the Phœnician or Tyrian Hercules, a god of great antiquity in Phœnicia.

BAAL-BERITH, the god of the Shechemites. Bochart conjectures that Berith is the same as *Beroe*, the daughter of Venus and Adonis, who was given in marriage to Bacchus; and that she gave her name to the city of Berith in Phœnicia, of which she became the patron goddess.

BAAL-PEOR, *Baal-phegor*, or *Beel-phegor*, an idol of the Moabites and Midianites. Baal-peor is identified by Jerome with *Priapus;* by Selden, again, with Pluto—which he grounds upon these words of the Psalmist, "They joined themselves unto Baal-peor, and ate the offerings of the dead;" and by others, with *Chemosh*.

BAAL-ZEBUB, *Beel-zebub*, or *Belzebub*, the god of the Ekronites. In Scripture he is called the Prince of Devils. His name is usually rendered the "Lord of Flies," which, some think, was a mock appellation bestowed on him by the Jews. But Scaliger derives the name from *Baalim-zebahim*, which signifies the "Lord of Sacrifices."

BAALBEC, an ancient city of Syria, celebrated for the magnificence of its ruins, which, with the exception of those at Palmyra, are the most extensive in Syria. Baalbec in the Syrian language signifies the "City of Baal," or of the Sun, and the Greek name Heliopolis (*i.e.* city of the sun) is a translation of this term. It is supposed to be the same with the Baal-Gad of Scripture said to be "in the valley of Lebanon under Mount Hermon." There is not sufficient authority for supposing this to be the Baalath built or fortified by Solomon. It is pleasantly situated on the lowest declivity of the Anti-Libanus, at the opening of a small valley into the plain El-Bekaa, 109 geographical miles from Palmyra, and 38¾ from Tripoli; Long. 36. 11. E. Lat. 34. 1. 30. N. Through this valley runs a small stream divided into numberless rills for irrigation.

The origin of this city appears to be lost in the most remote antiquity, and the historical notices of it are very scanty; the silence of the classical writers respecting it would alone seem to imply that it had previously existed under another name. In the absence of more positive information, we can only conjecture that its situation on the high road of commerce between Tyre, Palmyra, and the farther East, must have contributed largely to the wealth and magnificence which it manifestly attained. It is mentioned under the name of Heliopolis by Josephus (*Antiq.* xiv. 3, 4), and also by Pliny (*Hist. Nat.* v. 22). Two Roman inscriptions of the time of Antoninus Pius give sanction to the statement of John of Antioch, who alleges that this emperor built a great temple to Jupiter at Heliopolis, which was one of the wonders of the world (*Hist. Chron.* lib. xi.) From the reverses of Roman coins we learn that Heliopolis was constituted a colony by Julius Cæsar; that it was the seat of a Roman garrison in the time of Augustus; and obtained the *Jus*

Baalbec. *Italicum* from Severus. Some of the coins of later date contain curious representations of the temple.

From the accounts of Oriental writers, Baalbec seems to have continued a place of importance down to the time of the Moslem invasion of Syria. They describe it as one of the most splendid of Syrian cities, enriched with stately palaces, adorned with monuments of ancient times, and abounding with trees, fountains, and whatever contributes to luxurious enjoyment. After the capture of Damascus it was regularly invested by the Moslems, and after a courageous defence, at length capitulated. The ransom exacted by the conquerors, consisted of 2000 ounces of gold, 4000 ounces of silver, 2000 silk vests, and 1000 swords, together with the arms of the garrison. It afterwards became the mart for the rich pillage of Syria; but its prosperity soon received a fatal blow from the khalif of Damascus, by whom it was sacked and dismantled, and the principal inhabitants put to the sword (A.D. 748). During the Crusades, being incapable of making any resistance, it seems to have quietly submitted to the strongest. In the year 1400 it was pillaged by Timour Beg, in his progress to Damascus, after he had taken Aleppo. Afterwards it fell into the hands of the Metaweli—a barbarous predatory tribe, who were nearly exterminated when Djezzar Pasha permanently subjected the whole district to Turkish supremacy.

From the S., the city is first discovered at the distance of about a league and a half, behind a hedge of trees, over the verdant tops of which appears a white edging of domes and minarets. After about an hour's journey the traveller reaches this hedge, which is composed of very fine walnut trees, and soon after, crossing some ill-cultivated gardens by winding paths, arrives at the entrance of the city. Here he perceives a ruined wall, flanked with square towers, which ascends the declivity to the right, and traces out the precincts of the ancient city. This wall, which is only ten or twelve feet in height, admits a view of those void spaces and heaps of ruins which are invariable characteristics of every Turkish city; but what principally attracts attention is a large edifice on the left, which, by its lofty walls and rich columns, is soon recognized as one of those temples which antiquity has left for our admiration. These ruins, which are among the most beautiful and best preserved of any in Asia, merit a particular description.

To form a just idea of them, the reader must imagine himself descending from the interior of the town. After crossing the rubbish and huts with which it is filled, the first thing deserving of notice is a vacant space, which appears to have been a square: there, in front, towards the west, is a grand ruin, consisting of two pavilions ornamented with pilasters, joined at their lower angle by a wall 160 feet in length. This front commands the open country from a sort of terrace, on the edge of which are with difficulty distinguished the bases of twelve columns, which formerly extended from the one pavilion to the other, and formed a portico. The principal gate is obstructed by heaps of stones; but, that obstacle surmounted, the traveller enters an empty space, which is a hexagonal court of 180 feet in diameter. This court is strewed with broken columns, mutilated capitals, and the remains of pilasters, entablatures, and cornices; and around it is a row of ruined edifices, which display ornaments of the richest architecture. At the end of this court, towards the west, is an outlet, which formerly was a gate, through which is perceived a still more extensive range of ruins, of great magnificence. To have a full view of these, it is necessary to ascend a slope, at the top of which is the entrance to a quadrangular court much more spacious than the former, being 350 feet in width and 336 in length. The eye is first attracted to the end of this court, where are six enormous and majestic columns nearly entire. Another object not less interesting is a second range of columns to the left, which appear to have formed part of the peristyle of a temple. Baalbec. But the edifices which inclose this court on either side claim attention in the first instance. These form a sort of gallery containing various chambers, seven of which may be reckoned in each of the principal wings, namely, two in a semicircle, and five in an oblong. The base of the apartments still retains pediments of niches and tabernacles, the supporters of which have been destroyed. On the side of the court they are open, while four columns on the one side and six on the other have been totally destroyed. It is not easy to conceive the use of these apartments; but this does not lessen the admiration excited by the beauty of their pilasters and the richness of the frieze of the entablature. Neither is it possible to avoid remarking the singular effect which results from the mixture of the garlands, the large foliage of the capitals, and the sculpture of wild plants, with which they are everywhere ornamented. In the middle of the court is a little square esplanade, where anciently stood a pavilion, of which nothing now remains but the foundation. With regard to the six columns above mentioned, it is impossible to survey them without being struck with the boldness of their elevation and the richness of their workmanship. Their shafts are 21 feet 8 inches in circumference, and 58 in height; and the total height, including the entablature, is 75 feet 10 inches. The sight of this superb ruin, thus solitary and desolate, is exceedingly imposing; but a more attentive examination discovers a series of foundations, marking an oblong of 268 feet in length and 146 in width, which probably formed the peristyle of a grand temple, the primary purpose of this whole structure. It presented to the great court, that is, to the E., a front of 10 columns, with 19 on each side; which, with the six already mentioned, make in all 54. The ground on which it stood is an oblong, on a level with the court, but considerably narrower, so that there was only a terrace of 27 feet wide round the colonnade; while the esplanade thus produced fronts the open country towards the W., by a sloping wall of about 30 feet. In approaching the city this descent becomes less steep, so that the foundation of the pavilion is on a level with the termination of the hill; whence it is evident that the whole ground of the courts has been artificially raised. Such seems to have been the former state of this edifice; but the southern side of the grand temple was afterwards blocked up in order to build a smaller one, the peristyle and walls of which are still remaining. This temple, situated somewhat lower than the other, presents a side of 13 columns by 8 in front, or 32 in all. These are likewise of the Corinthian order: their shafts are 15 feet 8 inches in circumference, and 44 feet in height. The building they surround is an oblong, the front of which, turned towards the E., is out of the line of the left wing of the great court. To reach it the traveller must cross trunks of columns, heaps of stone, and a ruinous wall, by which it is now hid. After surmounting these obstacles, he arrives at the gate, where he may survey the inclosure which was once the habitation of a god; but, instead of the awful scene of a prostrate people, and sacrifices offered by a multitude of priests, the sky is seen through the open roof, which lets in light enough to show a chaos of ruins covered with dust and weeds. The walls, formerly enriched with all the ornaments of the Corinthian order, now present nothing but pediments of niches and tabernacles, of which almost all the supporters have fallen to the ground. Between these niches is a range of fluted pilasters, the capitals of which support a broken entablature; but what remains displays a rich frieze of foliage resting on the heads of satyrs, horses, bulls, and other animals. Over this entablature was the ancient roof, which was 57 feet in width and 110 in length. The walls which supported it are 31 feet high, and without a window. It is impossible to form any idea of the ornaments of this roof, except from the fragments lying on the ground; but it could scarcely have been richer in orna-

Baba ‖ Baboon.

ment than the gallery of the peristyle. The principal remaining parts contain tablets in the form of lozenges, on which are represented Jupiter seated on his eagle, Leda caressed by the swan, Diana with her bow and crescent, and several busts of emperors and empresses. It is unnecessary to enter more minutely into the description of this astonishing edifice. The lovers of the arts will find it described with the greatest truth and accuracy in a work published at London in 1757, under the title of *Ruins of Baalbec*, by Messrs Wood and Dawkins, as well as in the more recent works of Volney, Burckhardt, Richardson, Addison, Lord Lindsay, and Dr Wilson.

The present Baalbec is a miserable village, to the east of the ruins, consisting of a few mud-built houses, with a population not exceeding 2000.

BABA, Cape, the ancient Lectum, on the coast of Anatolia, a promontory between Mytelene and Tenedos. It is bold and rocky, and is in Lat. 39. 30. N. Long. 26. E.

BABATAG, or Babadag, a city in the government of Bulgaria and sanjak of Silistria, in Turkey in Europe. It stands on the lake or estuary Rasein, which communicates with the Black Sea, and is surrounded by mountains covered with woods. Pop. 10,000, amongst whom are many Jews and Greeks. It used to be the winter headquarters of the Turkish army during their wars with Russia. Long. 28. 32. E. Lat. 44. 55. N.

BABEL, a city and tower attempted to be built by the human race soon after the Flood, and remarkable for the miraculous frustration of the attempt by the confusion of languages (Gen. xi. 1–9.) Most authors are of opinion that the ancient Babel occupied the exact site of the future Babylon. The expression "*reach unto heaven*," as our translation of the Hebrew text has rendered it, may be well translated *represent the heavens;* hence some suppose that the top of this tower was not meant to reach up to heaven, but to be consecrated to the heavens, that is, to the worship of the sun, moon, and stars, of the fire, air, &c., and other natural powers, as deities. Less speculative persons think that the tower was erected as a fortress for the establishment of tyrannical power. It is generally supposed to be the same with the tower of Belus, described in the article Babylon.

BABELMANDEB (i.e. *the gate of tears*, so called from the dangers attending its navigation, or, according to an Arabic legend, from the numbers who were drowned by the earthquake which separated the coasts of Asia and Africa) is the strait lying between the coasts of Arabia and Abyssinia, and connecting the Red Sea with the Indian Ocean. The distance across, from a projecting cape on the Arabian shore to the opposite coast of Africa, is about 20 miles. The intermediate space contains several small islands, Perim, the largest, being in Lat. 12. 35. 30. N. Long. 43. 28. E. Perim divides the strait into two channels, of which the eastern, though the smaller, is the most frequented. It is from 1½ to 4 miles in breadth, with a depth of from 7 to 14 fathoms: the western channel has a depth of about 180 fathoms.

BABER, Zehir-Ed-din Mohammed, the founder of the Indian Mogul or Tatar empire, was the fifth in descent from Timur. After two unsuccessful attempts, he succeeded in 1519 in subjugating Hindustan; and extended his conquests from the Indus to the Ganges, subduing Afghanistan, the Punjaub, and Delhi. See Hindustan. (*Memoirs of the Emperor Baber*, translated by Leyden and Erskine, 1826.)

BABINGTON, Gervase, bishop of Worcester, was born, according to Fuller, in Nottinghamshire; but in what year is uncertain. He died in 1610. All the historians who have mentioned this prelate give him the character of a learned and pious man. His works, consisting of Notes upon the Pentateuch, an Exposition of the Creed, &c., were printed both in folio and quarto in 1615, and again in folio in 1637.

BABOON. See Mammalia, *Index*.

Babrius. ‖ Babylon.

BABRIUS, Babrias, or Gabrias, an ancient Greek fabulist, whose metrical tales are quoted by Suidas and others. Fragments only of them were known until lately, when M. Minoïde Mynas discovered a MS. copy in the convent of St Lawrence on Mount Athos, and transcribed 123 of them, which were first published at Paris in 1844, by Boissonade, with a Latin translation. Babrius probably flourished about the Augustan era. His fables have since been edited by Lachmann, Berol. 1845; by Orelli and Baiter, Turic. 1845; and by G. C. Lewis, Lond. 1847.

BABYLON, the metropolis of the Babylonio-Chaldæan empire, was situated in a wide plain on both sides of the River Euphrates, which divided it into two nearly equal parts. Ancient writers are not agreed as to who was the founder of this city,—some ascribing it to Semiramis, and others to Belus. It is generally supposed to have been the same with, or at least to have occupied the site of, the Babel of Nimrod's kingdom. The tower of Belus in like manner is supposed to have been the same with that of Babel; and indeed Babel is the only name given in the Hebrew or Chaldee of the Bible to this city. But by whomsoever it was founded, it was only after the fall of the Assyrian empire that it became the capital of the Eastern world; and Nebuchadnezzar was the person to whom it was chiefly indebted for those immense structures that made it one of the wonders of antiquity.

Ancient Historians.

Of the accounts given of this city by ancient authors, that of Herodotus is undoubtedly the one upon which the greatest reliance can be placed. Not only is he the earliest profane writer upon this subject, but he is the only ancient historian that we know to have been there in person, and that, too, while it was yet in a state of tolerable preservation; and although he may be liable to the imputation of occasionally retailing marvellous stories, yet in no one instance, where he speaks from his own observation, can he be accused either of partiality or invention. Diodorus is by no means so well entitled to credit as Herodotus; for, never having been there in person, his account is taken from other writers, and chiefly from Ctesias, an author of no great authority. We have no proof that either Arrian or Strabo visited Babylon, though the treatise of the former is valuable from his information being derived from the notes of Aristobulus, and Ptolemy the son of Lagus, who were there with Alexander. Quintus Curtius also formed his account upon the reports of the followers of Alexander, many of whom kept journals of the expedition.

Description of city.

According to Herodotus, Babylon was built in the form of a square—each side of which was 120 stadia in length; its circumference being therefore 480 stadia, or 55 of our miles. It was surrounded by a wall 87 feet thick, and 350 feet high, outside of which was a vast trench filled with water, and proportioned in depth and width to the elevation of the wall. The earth taken out of the trench was made into bricks for the construction of the wall. These were baked in furnaces, and afterwards cemented by heated bitumen, and layers of reeds were interposed for thirty courses of bricks. Upon the extreme margins of the wall a number of buildings of one story were erected opposite each other, with sufficient space between them for a chariot drawn by four horses to turn round. Another wall encircled the city within this one, not much weaker, but more narrow. The city was divided into two parts by the River Euphrates, along each bank of which extended an embankment of furnace-dried bricks. There were in all 100 gates in the wall; that is 25 on each of the four sides, all of brass, the posts and lintels being of the same metal. The city, which contained several houses of three or four stories, was intersected by streets running from each of the gates, and crossing each other at right angles. Opposite the ends of the streets leading to the river were openings in the embankments with brazen gates, and steps leading down to the

Babylon. river; and these gates were open by day but shut by night. It was by means of these gates, which had been left open, that Cyrus obtained access into the city.

Tower of Belus. In each of the two divisions of the city, in a conspicuous situation, was a walled inclosure, in the one of which was the palace, and in the other the temple of Belus. The latter inclosure was a square of two stadia, in the middle of which stood a solid tower of a stadium both in length and breadth. Upon this tower stood another tower, and another upon that, to the number of eight. The ascent to them was made in a circular form, leading round all the towers on the outside, with resting-places in the middle of the ascent. This temple, according to Strabo, was also a stadium in height; but this is not mentioned by Herodotus. Here was a large golden image of the god, and near it a golden table, the pedestal and pediment being of the same metal. These were said by the Chaldæans to have been made out of 800 talents of gold. There was also in the temple a golden statue of 12 cubits—"but this," says Herodotus, "I did not see,"—and many other statues and sacred vessels. This tower stood till the time of Xerxes; who, on his return from his Grecian expedition, having first plundered it of its immense wealth, laid it in ruins. Alexander, on his return to Babylon from his Indian expedition, proposed to rebuild it, and accordingly set 10,000 men to clear away the rubbish; but the work proved too herculean for such means, and his death happening soon after, put a stop to all further proceedings.

Palaces. The palace of Nebuchadnezzar was eight miles in circumference, and splendidly decorated with statues of men and animals. On the opposite side of the river, according to Diodorus, stood the old palace of the kings of Babylon; but it was much inferior in size to the new one, being only about four miles in circumference. The two palaces were connected by means of a bridge of great beauty thrown across the river, as well as by a subterraneous passage.

Hanging gardens. Nothing, however, at Babylon, was more wonderful than the hanging gardens which Nebuchadnezzar constructed in compliance with a wish of his queen Amytis, to possess elevated groves such as she had enjoyed on the hills around her native Ecbatana. For this purpose an artificial mountain was reared, in the form of a square, of four plethra or 400 feet on each side, with terraces rising one above another to a height overtopping the walls of the city; the ascent from terrace to terrace being by steps ten feet wide. The terraces were reared to their various stages on ranges of regular piers, which, forming a kind of vaulting, rose in succession, one over the other, to the required height of each terrace, the whole being bound together by a wall 22 feet thick. The floor of each terrace or garden was formed in the following manner: on the tops of the piers was first laid a pavement of flat stones, 16 feet in length and 4 in breadth, over which was a layer of reeds, mixed with a great quantity of bitumen; and this, again, was covered with two courses of bricks closely cemented together with plaster; while over all these were placed thick sheets of lead, on which was laid the earth or mould of the garden. This floorage was designed to retain the moisture of the mould; and in order to provide a sufficient depth for the largest trees to take firm root, immense hollow piers were built and filled with earth. Upon the uppermost of these terraces was a large reservoir, supplied with water from the river by means of an engine; and from this reservoir the terraces were irrigated, as occasion required.

Canals. Canals were cut out on the east side of the river, above the town, to prevent any inconvenience from its swellings, by conveying the superabundant waters into the Tigris. The principal of these was the Naher Malcha, or Royal Canal.

A lake was dug to the west of the city to receive the waters of the river while the embankments on each side of it were building. This lake is said to have been 160 miles in circuit, and 35 feet in depth. After the completion of the embankments, the lake and the canal which led to it were preserved, having been found very useful as a reservoir, from which, by means of sluices, the water was let out on certain occasions, for the irrigation of the land. Babylon. Lake.

Such is the description given by ancient historians of this city, which must have been much larger than we can form an idea of by comparison with the largest modern cities. Much doubt has been cast upon the statements of Herodotus as to the immense size of this city; but even taking the account of Diodorus, who ascribes to it the least extent of any of the ancient authors, it had a circuit of 41 of our miles, while Herodotus makes it 55 miles. Moreover, if we confine the city to the limits assigned by Diodorus, it will not include all the existing remains; whereas the limits assigned by Herodotus include all those venerable ruins in the vicinity of Hillah, that still astonish us by their stupendous dimensions. The accuracy and truthfulness of Herodotus whenever he speaks, as in this instance, from his own observations, entitle him to greater credit than Diodorus, who had his account only at second-hand. Nor, when we consider the vast pyramids of Egypt, or the wall of China, is there any reason to doubt the ability of Nebuchadnezzar or others to raise these immense walls and structures with their tens of thousands of captives. Authors have attempted to reduce the extent of the city as given by Herodotus, by questioning the length of the stadium used by him. Ukert, however, has satisfactorily shown that the Greeks had not different standards of measurement, but always used the Olympic stadium. The differences between the distances of places as given by the ancients, compared with their modern measurements, are accounted for by these distances not being measured, but computed by the number of stadia that a good traveller could perform in a day, which would vary considerably according to circumstances. It seems most probable, however, that in this instance Herodotus converted the Babylonian measurements into Grecian stadia. (See Smith's *Dictionary of Greek and Roman Antiquities—Art. Mensura.*) Extent.

We cannot, however, suppose that the population of Babylon bore any proportion to its size, or that in this respect it resembled our densely peopled modern towns. It is generally supposed that it at no period contained more than two millions of inhabitants. It indeed rather resembled an inclosed district, where every house was a villa, than a closely built town. The statement of Herodotus that some of the houses were three or four stories high, clearly indicates that they were not generally of that height; and probably most of them had only one story. "Quintus Curtius says positively that there was pasture and arable land in the inclosure, sufficient to support the whole of the population during a long siege; and Xenophon reports, that when Cyrus took Babylon (which event happened at night), the inhabitants of the opposite quarter of the town were not aware of it till the third part of the day, *i. e.* three hours after sunrise; which was very possibly owing to the great distance of one cluster of houses from another, since, had they been connected with each other in regular streets, the noise and confusion would, I think, have spread the information of the event with much greater rapidity."—(*Rich.*) Population.

The destruction of Babylon has generally been referred to the migration of its inhabitants to Seleucia, about 300 years before Christ. How long it survived the establishment of that colony does not appear; all we know is, that, in the time of Diodorus, the greater part of its area was ploughed up; and St Jerome in the fourth century describes it as a hunting park of the Parthian kings.

There can be little doubt that the ruins in the vicinity of Hillah, a small town on the banks of the Euphrates, about forty-eight miles S. of Baghdad, are those of the ancient Babylon. 1*st*, The whole district has been known from the Site.

Babylon. most ancient times by the name of *El-aredh Babel, i. e.* the Land of Babel. 2*d*, Its position on the Euphrates, and its distance from the bituminous fountains of Is or Hit, as given by Herodotus and from Seleucia, as given by Strabo. 3*d*, The character and extent of these ruins. If these be not the ruins of the ancient Babylon, there are no remains elsewhere in Mesopotamia to correspond with the vast edifices of that great city.

Modern travellers. The traveller who has devoted most time and patience to the illustration of Babylon and its ruins is Mr Rich, who, during the many years that he resided at Baghdad as British resident, had great facilities and opportunities for the task he undertook. Among the travellers who visited these ruins before his time was Pietro della Valle, who was there in 1616, and has left a fuller account of them than any previous traveller. In 1657 a Carmelite monk, named Vincenzo Maria di S. Caterina di Sienna, sailed up the Euphrates from Bassorah; but his account of the various places which he passed is so mixed up with geographical errors as to be almost unintelligible. A few years later, another Roman Catholic missionary, Pere Emanuel de S. Albert, visited and described the ruins, with much greater minuteness and accuracy than his predecessor. Niebuhr visited them in 1765, and mentions that the place was still called *Ard-Babel*, and that on both sides of the Euphrates were mounds or little hills full of bricks. M. Beauchamp, who resided for some years at Baghdad as the pope's vicar-general, had frequent opportunities of visiting and examining the ruins. He drew up, on the spot, a memoir, which was read before the Academie des Belles Lettres, and printed in their journal for December 1790.

Rich's account of the ruins. According to Rich, the ruins of Babylon, on the eastern side of the Euphrates, may be said to commence at Mohawil; the whole country between that and Jumjuma, two miles from Hillah, exhibiting at intervals traces of building, in which are discoverable burnt and unburnt bricks, and bitumen. Three mounds, in particular, attract attention from their magnitude, Amran, Kasr, and Mujelibé.

In proceeding northwards from Hillah, and after passing some smaller mounds, he came to a vast mass 1100 yards in length, and 800 in its greatest breadth, whilst its most elevated part rose 50 or 60 feet above the level of the plain.

Amran. Just below the highest part of it is a small dome, in an oblong inclosure, said to contain the body of a son of Ali, named Amran, together with seven of his companions, all slain at the battle of Hillah. This, however, is one of those frauds not uncommon with the natives, Ali having had no such son. Mr Rich distinguishes this mound by the name of Amran.

Kasr. North of Amran is a valley of 550 yards in length, crossed by lines of ruins of little elevation, and to this succeeds the second grand mass of ruins, which is nearly a square of 700 yards in length and breadth. This is the most interesting part of the ruins of Babylon; every vestige discoverable in it showing it to have been composed of buildings far superior to any other edifice, in the eastern quarter, of which we have any traces. It has, however, been excavated and hollowed out in every direction by workmen, in extracting the bricks, which are of the finest description. In these excavations, walls of burnt brick, laid in lime mortar of a very good quality, are seen; and in addition to the substances generally strewed on the surfaces of these mounds, are found fragments of alabaster vessels, fine earthenware, marble, and great quantities of varnished tiles, the glazing and colouring of which are remarkably fresh. Here Mr Rich found a lion of colossal dimensions standing on a pedestal of a coarse gray granite, and of rude workmanship;—in the mouth was a circular aperture into which a man might introduce his fist. A part of this ruin, called by the natives the Kasr or palace, but which term Rich applies to the whole mass, is so remarkably fresh in appearance, that it was only after a minute inspection that he was satisfied as to its being a Babylonian remain. It consists of several walls and piers (which face the cardinal points) eight feet in thickness, in some places ornamented with niches, and in others strengthened by pilasters and buttresses, built of fine burnt brick (still perfectly clean and sharp), laid in lime cement of such tenacity that it is extremely difficult to extract them whole. The tops of these walls are broken, and may have been much higher; and some detached walls of the same kind standing at different distances show what remains to have been only a small part of the original fabric. A little to the N.N.E. of this ruin is the famous tree called by the Arabs *Atheleh*, and which they affirm to have flourished in the ancient Babylon, having been preserved by God from the destruction which overwhelmed that city, that it might afford shelter to the Khalif Ali after the battle of Hillah. They assert that there is no other tree of the kind in the world; it is, however, believed to be a species of tamarisk. Its trunk, which was once enormous, is now so worn away, that nothing more than one side of it remains; yet it bears spreading and ever-green branches, which are peculiarly beautiful, being adorned with long tress-like tendrils resembling heron-feathers growing from a central stem. These slender and delicate sprays bending towards the ground give the whole the appearance of a weeping willow, while their gentle waving in the wind produces a low and melancholy sound.

Mujelibé. A mile to the N. of the Kasr, or fully five miles from Hillah, and 950 yards from the river bank, is the mound called by the Arabs *Mujelibé*, or *overturned*. Its shape is oblong; its height irregular; and its sides face the cardinal points. The northern side is 200 yards in length, the southern 219, the eastern 182, and the western 136; and the elevation of the S.E. or highest angle is 141 feet. The western side, which is the least elevated, is the most interesting, on account of the appearance of building it presents. Near its summit appears a low wall composed of unburnt bricks, mixed up with chopped straw or reeds, and cemented with clay-mortar of great thickness, having between each layer of bricks a layer of reeds. On the N. side are also some vestiges of a similar construction. The S.W. angle is crowned by something like a turret or lantern; the other angles are in a less perfect state, but may originally have been ornamented in a similar manner. All the sides are worn into furrows, which in some instances are of great depth. The summit is covered with heaps of rubbish, in which layers of broken burnt bricks cemented with mortar have been found, and also entire bricks with inscriptions. Scattered over the whole are fragments of pottery, brick, bitumen, pebbles, vitrified brick or scoria, and even shells, bits of glass, and mother-of-pearl. In the northern face, near the summit, is a niche or recess high enough for a man to stand upright in, at the back of which is a low aperture leading to a small cavity, whence a passage branches off to the right, sloping upwards in a westerly direction till it loses itself in the rubbish. Being informed that in this place, about four years previously, a human body had been found, swathed in a wrapper partially covered with bitumen, and inclosed in a coffin of mulberry wood, Rich was induced to excavate here. He dug into a shaft or hollow pier 60 feet square, lined with fine brick, laid in bitumen and filled with earth; in this was found a brass spike, some earthen vessels, and a beam of date-tree wood. After digging some way farther, they came to a narrow passage nearly ten feet high, flat on the top, and exhibiting both burnt and unburnt bricks; the former with inscriptions on them, and the latter, as usual, laid with a layer of reeds between each row, except in one or two courses near the bottom, where they were cemented with bitumen. In a continuation of this passage to the eastward, he discovered a wooden coffin containing a skeleton in good preservation. Under the head of the coffin was

Babylon. a round pebble; attached to the coffin on the outside was a brass bird, and inside an ornament of the same material, which had apparently been suspended to some part of the skeleton. A little farther, the skeleton of a child was found. About 70 yards from the foot of the Mujelibé, on the northern and western sides, are traces of a low mound of earth which may have formed an inclosure round the whole.

Western side. Mr Rich, after examining the eastern side of the Euphrates, proceeded to take a survey of the remains on the western side of that river. He found the whole bank to be a flat, intersected by canals, the principal of which were the Tajia or Ali Pacha's trench and the canal of Tahmasia. The only vestiges were two small mounds of earth opposite the mass of Amran, overgrown with grass, forming a right angle with each other, and a little farther on two similar ones. These did not exceed 100 yards in extent, and the place was called by the peasants Anana.

Birs Nimroud. But although there are no ruins in the immediate vicinity of the river, by far the most stupendous and surprising mass of all the remains of Babylon is situated in this desert about six miles to the S.W. of Hillah. It is called by the Arabs Birs Nimroud, and by the Jews Nebuchadnezzar's Prison. It is a mound, of an oblong figure, the total circumference of which is 762 yards. At the eastern side it is not more than 50 or 60 feet high, and is cloven by a deep furrow; but at the western it rises in a conical form to the height of 198 feet; and has on its summit a solid pile of brick 37 feet high by 28 in breadth, and diminishing in thickness to the top. It is perforated by small square holes disposed in rhomboids. The bricks are of the finest description, with inscriptions on them, and so well cemented, apparently with lime mortar, that it is nearly impossible to extract one of them entire, though the layers are so close together that it is difficult to discern what substance is between them. The other parts of the summit of this hill are occupied by immense fragments of brick-work of no determinate figure, tumbled together and converted into solid vitrified masses, as if they had undergone the action of the fiercest fire or been blown up with gunpowder. The whole of this mound is channelled by the weather, and strewed with the usual fragments, and with pieces of black stone, sandstone, and marble. No reeds were discernible in any part, a circumstance which Mr Rich thinks may be an argument for the superior antiquity of this ruin. At the foot of the mound, a step may be traced scarcely elevated above the plain, exceeding in extent, by several feet each way, the true or measured base; and there is a quadrangular inclosure surrounding the whole as at the Mujelibé, but much more perfect and of greater dimensions. At a short distance, and parallel with its eastern face, is a mound not inferior to the Kasr in elevation, but much longer than broad. There are numerous other mounds besides those described, but the principal of them are beyond any possible limits that can be ascribed to Babylon; as the ruins called by the natives Boursa, four leagues below Hillah, and which Mr Rich conjectures to be the Borsippa of Strabo, and the Barsita of Ptolemy. Such was the state of the ruins of this ancient city when visited by Mr Rich: we shall now give a short account of Mr Layard's recent visit, and conclude with an attempt to identify some of these remains with parts of the ancient city.

Layard's account. The successes that attended the labours of Mr Layard among the ruins of Nineveh induced him to turn his attention also to those of Babylon. He accordingly proceeded there with a party of workmen; but after various excavations, the discoveries were far less numerous and important than he had anticipated, "nor did they tend to prove that there were remains beneath the heaps of earth and rubbish which would reward more extensive excavations." This is to be accounted for by the city having been built in the midst of an alluvial country far removed from the hills, and with no quarries of alabaster or limestone such as existed near Nineveh. The people were therefore content to use such building materials as were to be found on the spot, and made bricks with the mud of their alluvial soil, while bitumen and other substances from the vicinity furnished them with an excellent cement; and the walls of their temples and palaces were coated with mortar and plaster. The ornaments and paintings on these would consequently not be so durable as the sculptures on the slabs and stones of Nineveh. Babylon.

During Mr Layard's stay at Babylon, the troubled state of the country prevented him from making more than a hurried visit to Birs Nimroud. In the mound of Mujelibé he sought the subterranean passage which had been previously opened and described by Mr Rich; and on removing the rubbish, he soon came to that part of the passage where Mr Rich found the coffin of wood, containing a skeleton still well preserved. "The entrances to other galleries which had not been explored, were still closed with large burnt bricks, amongst which were a few square stones inscribed on one edge with two lines of cuneiform characters, containing the name and titles of Nebuchadnezzar, king of the Chaldees, the inscription usually found on Babylonian bricks. It was evident that they had originally belonged to an edifice erected by that monarch, and had been taken from its ruins to form this covering to the vaults and tombs. Beneath this masonry were found several entire coffins precisely similar to that discovered by Mr Rich. They still held skeletons more or less entire, which fell to pieces as soon as exposed to the air. No relic or ornaments had been buried with the bodies. The wood of the coffins was in the last stage of decay, and could only be taken out piecemeal." "The coffins discovered at Babel (Mujelibé) are of a comparatively recent period, and are not pure Babylonian. At the very earliest, they may be of the time of the Seleucidæ, but I am inclined to think that they are even of a still later date. It is evident that they were buried after the destruction of the edifice covered by the mound. Upon that great heap over the fallen palace or temple, was probably raised one of those citadels which formed the defences of a city built long after the destruction of the Babylonian empire and its magnificent capital, and which resisted the arms of Demetrius Poliorcetes. Of this stronghold the thick wall of sun-dried brick on the northern side is probably the remains."—(*Layard.*) The masonry of this wall is not united by bituminous cement, but apparently by simple mud, as in modern Arab buildings. Excavations and trenches were made in other parts of this mound, but without any important results. Mujelibé.

Numerous relics were found similar to those that had already been brought to this country by other travellers: among these were arrow-heads in bronze and iron, small glass bottles, some coloured or ornamented, and vases of earthenware of various forms and sizes, sometimes glazed with a rich blue colour. These are considered to belong to a period subsequent to the fall of the empire; the earliest probably about the time of the Greek occupation, and the latest about the sixth or seventh century of the Christian era. Mr Layard judging, therefore, that the remains of the ancient edifice, if any still existed, were to be sought far beneath the surface, opened tunnels at the foot of the mound, nearly on a level with the plain. On the eastern, western, and southern sides, they soon came to remains of solid masonry, evidently of the ancient building. On the eastern side eight or ten piers and several walls branching in various directions were uncovered, but no plan could be traced, nor any remains of sculptured stone or painted plaster discovered.

In the Kasr, the loose nature of the ruins prevented him from making any extensive excavations, and the only object of interest discovered was a fragment of limestone, on which were sculptured parts of two figures undoubtedly of gods, with the name of one of them inscribed in Babylonian characters. Excavations were made in several of the smaller mounds, but without any important results. Kasr.

Amran. In the mound Amran, or Amzan ben Ali, no traces of masonry were discovered, but some specimens of glass, and several terracotta figures, lamps, and jars were found. Among these were five cups or bowls of earthenware, and fragments of some others, covered on the inner surface with letters written in a kind of ink. The characters upon them are in form not unlike the Hebrew, and on some they resemble the Sabæan and Syriac. Similar relics have been found in other ruins near Babylon. Mr Thomas Ellis, of the manuscript department in the British Museum, was the first to decypher these inscriptions. The subjects are amulets or charms against evil spirits, diseases, and every kind of misfortune; one of them being a bill of divorce to the devil and other evil spirits. The writers were evidently Jews, probably descendants of those who were carried captive by Nebuchadnezzar into Babylon; and they must have been written long prior to any known existing manuscripts of the ancient Hebrew or Chaldæan languages, as, except in one case, there are no divisions between the words; nor are there any vowel points. —(Layard's *Nineveh and Babylon.*)

Identification of the ruins. The identification of the present ruins with parts of the ancient city has been found to be a matter of considerable difficulty. We are told that the city was built upon both sides of the river, and that its principal buildings were the tower or temple of Belus, Nebuchadnezzar's palace, and the hanging gardens; and the principal existing ruins are the mounds of Amran, Kasr, Mujelibé, and Birs Nimroud. The principal question has been, whether the Birs Nimroud or the Mujelibé represents the tower of Belus. Herodotus states that the tower and palace stood on opposite sides of the Euphrates; and previous to the time of Rich it was the received opinion that the latter had stood on the W. and the former on the E. side of that river. This was Mr Rich's opinion on visiting the Birs Nimroud; and on examining that ruin he could not help exclaiming, that "had this been on the other side of the river, and nearer the great mass of ruins, no one could doubt of its being the remains of the tower." As to the side of the river on which the tower stood, this is not expressly stated by any ancient author, and it had only been inferred from an ambiguity in the account of Diodorus. Notwithstanding the distance of the Birs Nimroud from the other remains, it would have been included within the city, if we consider as correct the account of Herodotus, who, as has been already said, is the most trustworthy of our ancient historians on this subject. If the Birs Nimroud form no part of the ruins of Babylon, it is surprising that it is not noticed by any ancient author, in giving an account of that city, which is scarcely credible, seeing that it is a mass of ruins "by far the most stupendous and surprising" of any that are allowed to belong to that city. It has been supposed, from Herodotus' having used the term ἐν μέσῳ in his description of the tower and palace, that they must each have been in the centre of their respective divisions. Though this term may generally be translated "in the centre," there is the highest authority for saying that, when used as it is in this case, it is very frequently applied to an object as lying in the way, or occupying a conspicuous position.—See *Schneider's Greek Lexicon*, by Passow.

Pietro della Valle was the first to assert that Mujelibé was the ancient tower, and his statement was followed, among others, by Major Rennell, author of the *Geography of Herodotus*. The opinion given out by Mr Rich that the Birs Nimroud might possibly represent the tower, called forth an article from Major Rennell in the Archæologia, in vindication of his own account of Babylon in the *Geography of Herodotus*. This was ably answered by Mr Rich in his *Second Memoir of Babylon*. Major Rennell rejects the idea that the Birs Nimroud was the temple of Belus, mainly on the ground that its distance was too great from the river and the rest of the ruins, to have been included in the circuit of the ancient city. According to him, the Mujelibé represents this temple, and considering this as certain, he proceeds to dispose of the other ruins in conformity with that. To make good this hypothesis, he is obliged to have recourse to the supposition that the river originally ran through the present ruins. This is denied by Mr Rich. "I carefully examined," says he, "the whole of the ground between Hillah and Mujelibé, with the view to ascertain the possibility of a change; but I was totally unable to discover the smallest vestiges indicative of it. The same examination was made by others during my stay, and since that time with the same result." This is also corroborated by Mr Layard, who says:—"After the most careful examination of the country, I could find no traces whatever of its having at any time flowed much farther than it now does to the east."

But the assertion that the river never flowed much farther to the eastward than it does at present, involves the question of what has become of the ruins on its western side, as it is expressly stated that the city stood upon both sides of the river. Niebuhr, who visited the spot in 1765, states that there were then mounds or little hills which were discovered to be full of bricks on both sides of the river; and Mr Rich says that he found opposite the mass of Amran two small mounds of earth overgrown with grass, and a little farther on two similar ones. Sir R. K. Porter seems to have subjected the plain on the western side of the Euphrates to a more minute examination, for the purpose of finding, if possible, some traces of the second palace. About 50 yards N.W. of Anana, a small village on the western bank of the river, 3 miles N.W. of Hillah, he found a considerable ridge of mounded earth 14 feet high, running due N. for 300 yards, and then, forming a right angle, continued on in that direction till it met the river. On the face of this ridge terminating at the water-edge, courses of sun-dried bricks are still distinctly visible; though the level of this land is now so equal with that of the river, that no traces are visible of any corresponding embankment on the other side. Some trifling mounds were observed a little to the S. of the village. After riding onward for about a mile to the S.W. in the direction of the Birs Nimroud, he found the vegetation gradually disappear, and the ground become perfectly sterile, presenting evident signs of its having been once covered with buildings. These indications increased at every step for more than a mile, when he came to another and more conspicuous range of mounds, the most considerable of which was about 35 feet high. From the top of this he observed that the face of the country, both to the N. and S., for more than a mile either way, bore the same hillocky appearance; besides being thickly scattered with those fragments of past habitations which in all Babylonian ruins have so particularly marked their character. "Here," says Sir R. K. Porter, "I think it is possible I may have found the site of the old or lesser palace; which, probably, was the temporary abode of Alexander during his inspection of his workmen, while clearing away the ruins of its fallen superstructures from the base of the temple of Belus. In the midst of the labour, and after having been engaged nearly two months in that attempt, we are told that he died; but previous to the event, he ordered himself to be removed from his residence on one side of the river to *his palace* on the other, and the eastern having been the more stately of the two, we can hardly entertain a doubt of its having also been the conqueror's more stationary habitation. Hence, there seems good reason to conclude, that it was on some spot amongst the ruins of the Kasr that the Macedonian hero breathed his last." Beyond this mass of mounds which, for perspicuity, he designates the Lesser Palace, and in the same direction (S.W.), he crossed a space of high grass and rank weeds for nearly a mile. He then found the plain again arid and undulated with multitudes of mounds, but of inferior elevation to those last described; these, too, were attended by the

Babylon. usual exterior fragments of ruins, spreading in a circular form for rather more than half a mile in width; then followed more than a mile of cultivated land to a canal which he crossed, and half a mile more brought him to an extensive wood of date trees, in the bosom of which stands the village of Tahmasia. For two miles the cultivation continued, and at the end of this a vast tract opened before him, covered with every minor vestige of former buildings, which appearances continued all the way to the eastern verge of the boundary around Birs Nimroud, a distance of nearly three-quarters of a mile. The remains seemed to him not only to establish the fact that the western plain of the Euphrates sustained its portion of the city of Babylon as well as the eastern bank, but that Birs Nimroud, otherwise the temple of Belus, did actually stand in one division of the city.

Mr Layard thinks that the fact of there being few remains on the western side may be accounted for from the Euphrates having a tendency to change its course in that direction, and to lose itself in the marshes to the W. of its actual bed. The low country on that side was subject to continual inundations from the earliest period; and Arrian states that the western quarter of the city was surrounded and defended by enormous marshes, which prevented all access to it. "Supposing, therefore, the river from different causes to have advanced and receded during many centuries, between the Hindiyah marshes and its present channel, it will easily be understood how the ruins which may once have stood on the western bank have gradually been washed away, and how the existing flat alluvial plain has taken their place."—(*Layard.*)

Captain Mignan, who has published the result of a most careful and meritorious survey of these ruins, adopts the opinion of Major Rennell, and asserts that the Birs Nimroud formed no part of the ancient Babylon. His description of the ruins, however, seem to tell rather against than for his opinion. The comparative claims of the two structures cannot bear comparison. The Mujelibé is an irregular oblong mass, little more than half the height of its rival, and composed almost entirely of the inferior material of sun-dried bricks. The Birs Nimroud, on the contrary, is much more elevated than any of the other remains, is built of the finest materials, and is of a form such as the tower is described to have been, having been evidently built in successive receding stages. Mr Buckingham is of opinion that the traces of four stages are clearly discernible. The opinion that this structure formed a part of the ancient city is strengthened by the observations of Captain Mignan, that instead of standing solitary, as had generally been supposed, it is surrounded by extensive ranges of ruins, bearing in their shattered fragments every mark of ancient importance. "If any building," says Mr Rich, "may be supposed to have left considerable traces, it is certainly the Pyramid or Tower of Belus, which, by its form, dimensions, and the solidity of its construction, was well calculated to resist the ravages of time; and if human force had not been employed, would, in all probability, have remained to the present day in nearly as perfect a state as the Pyramids of Egypt." "I am of opinion," he continues, "that this ruin is of a nature to fix of itself the locality of Babylon, even to the exclusion of those on the eastern side of the river; and if the ancients had actually assigned a position to the tower irreconcilable with the Birs, it would be more reasonable to suppose that some error had crept into their accounts than to reject this most remarkable of all the ruins."

It is stated by ancient writers in the most positive and circumstantial manner, that the palace, with its grand appendage of hanging gardens, was situate upon or very near the river, whence, indeed, the gardens were artificially watered. Now, modern Babylon presents near the river no ruins of any magnitude except those of the Amran, Kasr, and Mujelibé. It seems, therefore, unquestionable that some of these must be the remains of those immense structures. "In the Kasr we have remains of a pile, sumptuous in its material, of the finest furnace-baked brick, and magnificent for its extent, occupying a central position among the conspicuous ruins on the eastern bank, and inclosed on three sides by immense embankments answering to the description left us by Herodotus of the strong interior wall which surrounded the palace"—(Dr Traill in *Edin. Phil. Journal*, vol. xix.) The Mujelibé is by Mr Rich supposed to be the hanging gardens, and this is the generally received opinion, although some would give the preference to Amran, from its lying nearer the river. The opinion of Mr Rich seems to be strengthened by the piers discovered here by Mr Layard, and from no traces of masonry having as yet been found in the mound of Amran. The Amran and the embankment may probably have formed part of the defences of the city towards the river. It has been supposed that Diodorus is incorrect in stating that there were two palaces, especially as he is not supported by Herodotus or any other ancient authority; and as he wrote only from hearsay, that he might have been deceived by varying accounts of one palace, and thus led to form the idea that there were two. The striking similarity in his two descriptions as to situation, plan, and ornament, somewhat favours this conjecture. It is possible, however, that Sir R. K. Porter may be right in his supposition that he had found the site of the Lesser Palace. It thus seems extremely probable that the palace and the hanging gardens were situated on the eastern side of the Euphrates, and the tower of Belus on the western; that the Birs Nimroud was included within the walls of the ancient city, and is the remains of the tower of Belus, and that the Kasr represents the palace; while the Mujelibé not improbably corresponds to the hanging gardens.—See Rich's *First and Second Memoirs on the Ruins of Babylon*, 1815 and 1818; Major Rennell, *On the Topography of Ancient Babylon*, in *Archæologia*, vol. xviii.; Sir R. K. Porter's *Travels*, London, 1822; "*Remains of Babylon*," in *Edin. Review*, vol. xlviii.; Mignan's *Travels in Chaldæa*, Lond. 1829; Buckingham's *Travels in Mesopotamia;* Ainsworth's *Researches in Babylonia*, Lond. 1838; Keppell's *Personal Narrative;* Dr Traill, *On Ruins of Babylon*, in *Edin. Phil. Journal*, vol. xix.; *Nineveh and Persepolis*, by Vaux, Lond. 1850; Layard's *Nineveh and Babylon*, London, 1853. (D.K.)

Babylonia. BABYLONIA, or CHALDÆA, a country and kingdom of Asia, the capital of which was Babylon. The country was bounded on the N. by the desert part of Mesopotamia, on the E. by the Tigris, on the S. by the Persian Gulf, and on the W. by the Arabian desert. The confines of the kingdom, however, were at times much more extensive.

Passing over the early portion of Babylonian history, which is obscure and doubtful, we shall limit ourselves to a short acount of the events which terminated in the subversion of the kingdom.

A war which had begun between the Medes, Persians, and Babylonians, in the reign of Neriglissar, the father of Nabonadius, had been carried on with very bad fortune on the side of the Babylonians. Cyrus, who commanded the Median and Persian army, having subdued the several nations inhabiting the great continent from the Ægean Sea to the Euphrates, bent his march towards Babylon. Nabonadius, hearing of his march, immediately advanced against him with an army. In the engagement which ensued, the Babylonians were defeated; and the king, retreating to his metropolis, was blocked up and closely besieged by Cyrus. The reduction of this city was no easy enterprise. The walls were of a prodigious height, the number of men employed to defend them was great, and the place was stored with all sorts of provisions for twenty years. Cyrus, despairing of being able to take such a city by storm, caused a line of circumvallation to be drawn quite round it, with a large and deep ditch; reckoning that if all communication with the

Babylonia. country were cut off, the besieged would be obliged to surrender through famine. That his troops might not be too much fatigued, he divided his army into twelve bodies, appointing each body its month to guard the trenches; while the besieged, trusting to their high walls and magazines, insulted him from the ramparts, and ridiculed all his preparations as so much unprofitable labour.

After Cyrus had spent two whole years before Babylon, without making any progress in the siege, he at last thought of the following stratagem, which put him in possession of it. He was informed that a great annual solemnity was to be held at Babylon, and that the inhabitants on that occasion were accustomed to spend the whole night in drinking and debauchery. This he therefore thought a proper time for surprising them; and accordingly sent a strong detachment to the head of the canal leading to the large lake, with orders, at a certain time, to break down the great bank which was between the lake and canal, and to turn the whole current into the lake. At the same time he stationed one body of troops at the place where the river entered the city, and another where it came out; ordering them to march in by the bed of the river as soon as they should find it fordable. Towards the evening he opened the head of the trenches on both sides of the river above the city, that the water might discharge itself into them; by which means, and the breaking down of the great dam, the river was soon drained. The troops then entered the channel, the one body commanded by Gobryas, the other by Gadates; and finding the gates all left open in consequence of the disorders of that riotous night, they penetrated into the very heart of the city without opposition, and meeting, according to agreement, at the palace, they surprised the guards and cut them to pieces. Those who were in the palace opened the gates to know the cause of this confusion, when the Persians rushed in, took the palace, and killed the king, who came out to meet them sword in hand. Thus an end was put to the Babylonian empire; and Cyrus took possession of Babylon for one called in Scripture Darius the Mede, most probably Cyaxares II., uncle to Cyrus. From this time Babylonia never formed a distinct kingdom, but has always followed the fortune of those great conquerors who at different times have appeared in Asia. It is now subject to the Turks, under the name of Irak Arabi.

Of the country, manners, customs, and institutions of the Babylonians, a good account, chiefly gathered from Herodotus, has been given by M. Sabbathier in his *Manners, Customs, and Usages of Ancient Nations* (Stockdale's English translation, 2 vols. 8vo. 1775).

"As all the nations under the dominion of Cyrus, beside the ordinary tributes, were obliged to maintain him and his army, the monarch and his troops were supported by all Asia. The country of Babylon alone was obliged to maintain him four months of the year; its fertility, therefore, yielded a third of the produce of Asia. The government of this country, which the Persians termed *satrapy*, was richer and more extensive than any of the rest. It maintained for the king, besides the war-horses, a stud of 800 stallions and 16,000 mares. So great a number of Indian dogs were likewise bred in this province for the king, that four of its cities kept those animals; and in return, they were exempted from all taxes and tributes.

"It rained very seldom in this country, according to Herodotus. The earth was watered by the river, which was here diffused by human industry, as the Nile is over Egypt by nature; for all the country of Babylon was divided by canals, the greatest of which was navigable, and flowed from S. to N., from the Euphrates to the Tigris. In short, it was one of the finest countries for corn in the world; but for producing trees, the fig-tree, the vine, and the olive, it was not famous. It was so luxuriant in grain, that it commonly yielded a hundred times more than what was sown; and in good years it yielded three hundred times more than it received. The leaves of its wheat and barley were four inches broad. 'Though I know,' says Herodotus, 'that the millet and the sesame of that country grow to the size of trees, I will not describe them particularly, Babylonia. lest those who have not been in Babylonia should think my account fabulous.'

"They had no oil but what they made from Indian corn. The country abounded with palm-trees, which grew spontaneously; and most of them bore fruit, of which the inhabitants made bread, wine, and honey. They cultivated these trees and their fig-trees in the same manner. Some of them, as of other trees, the Greeks called *male* ones. They tied the fruit of the male to the trees which bore dates; that the musquitto, leaving the male, might cause the date to ripen, by penetrating it; for without that assistance it did not come to maturity. Musquittos bred in the male palms as in the wild fig-trees.

"But we must not here omit to give an account of the peculiar and surprising construction of their boats of skins, in which they sailed along the river to Babylon. These boats were invented by the Armenians, whose country lay north from Babylonia. They made them with poles of willow, which they bent, and covered with skins; the bare side of the skins they put outwards; and they made them so tight that they resembled boards. The boats had neither prow nor stern, but were of a round form like a buckler. They put straw on the bottom. Two men, each with an oar, rowed them down the river, laden with different wares, but chiefly with palm wine. Of these boats some were very large and some very small: the largest carried the weight of 500 talents. There was room for an ass in one of their small boats; they put many into a large one. When they had unloaded, after their arrival at Babylon, they sold the poles of their boats and the straw, and loading their asses with the skins, returned to Armenia; for they could not sail up the river, its current was so rapid. For this reason they made their boats of skins instead of wood; and on their return to Armenia with their asses, they applied the skins to their former use.

"As to their dress, they wore a linen shirt, which came down to their feet. Over it they wore a woollen robe; their outer garment was a white vest. Their shoes resembled those of the Thebans. They let their hair grow. On their heads they wore a turban. They rubbed their bodies all over with fragrant liquors. Each man had a ring on his finger, and an elegant cane in his hand, with an apple at the top, or a rose, a lily, or an eagle, or some other figure; for they were not suffered to use canes without devices.

"With regard to their policy, Herodotus thinks that their best law was one which the Heneti, an Illyrian people, likewise observed in every town and village. When the girls were marriageable, they were ordered to meet in a certain place, where the young men likewise assembled. They were then sold by the public crier: but he first sold the most beautiful one. When he had sold her at an immense price, he put up others to sale, according to their degrees of beauty. The rich Babylonians were emulous to carry off the finest women, who were sold to the highest bidders. But as the young men who were poor could not aspire to have fine women, they were content to take the ugliest with the money which was given them; for when the crier had sold the handsomest, he ordered the ugliest of all the women to be brought, and asked if any one was willing to take her with a small sum of money. Thus she became the wife of him who was most easily satisfied; and thus the finest women were sold, and from the money which they brought, small fortunes were given to the ugliest, and to those who had any bodily infirmity. A father could not marry his daughter as he pleased; nor was he who bought her allowed to take her home, without giving security that he would marry her. But, after the sale, if the parties were not agreeable to each other, the law enjoined that the purchase-money should be restored. The inhabitants of any of their towns were permitted to marry wives at these auctions. Such were the early customs of the Babylonians.

"But they afterwards made a law, which prohibited the inhabitants of different towns from intermarrying, and by which husbands were punished for treating their wives ill. When they had become poor by the ruin of their metropolis, fathers used to prostitute their daughters for gain. There was a sensible custom among the Babylonians, worthy to be related. They brought their sick into the forum, to consult those who passed on their diseases; for they had no physicians. They asked those who approached the sick, if they had ever had the

Babylonian || Bacchanalia.

same distemper; if they knew any one who had had it, and how he was cured. Hence, in this country, every one who saw a sick person was obliged to go to him and inquire into his distemper.

"They embalmed their dead with honey, and their mourning was like that of the Egyptians.

"There were three Babylonian tribes who lived only upon fish, and who prepared them in the following manner: they dried them in the sun, and then beat them in a mortar to a kind of flour, which, after they had sifted it through linen, they baked into rolls.

"The Babylonians at first worshipped only the sun and the moon; but they soon multiplied their divinities. They deified Baal, Bel, or Belus, one of their kings, and Merodach-Baladan. They also worshipped Venus under the name of *Mylitta*. She and Belus were the principal deities of the Babylonians. They counted their day from sunrise to sunrise. They solemnized five days of the year with great magnificence, and almost the same ceremonies with which the Romans celebrated their Saturnalia.

"The Babylonians were very much addicted to judicial astrology. Their priests, who openly professed that art, were obliged to commit to writing all the events of the lives of their illustrious men; and on a fancied connection between those events and the motions of the heavenly bodies the principles of their art were founded. They pretended that some of their books, in which their historical transactions and revolutions were accurately compared with the courses of the stars, were thousands of years old. This assertion of their judicial astrologers we may reasonably dispute; but that their astronomers had made a long series of observations is incontestably true. It is certain that some of these were extant in the days of Aristotle, and that they were older than the empire of the Babylonians." See ASTRONOMY, *History*.

BABYLONIAN, BABYLONIUS, is used by some ancient writers to signify astrologer, or anything relating to astrology. Hence *Babylonia cura* means the art of casting nativities; and *numeri Babylonii*, the computation of astrologers. See above.

BABYLONICA TEXTA, a rich sort of weavings or hangings, so called from the city of Babylon, where the art of interweaving divers colours in hangings or tapestry was first practised. Hence also Babylonic garments, Babylonic skins, Babylonic carpets, housings, &c.

BACCALAUREATE, the degree of bachelor of arts. See UNIVERSITIES.

BACCARAT, a town of France, capital of a canton in the department of Meurthe, 15 miles S.E. of Luneville. It is celebrated for its glass works, the most extensive in France, and which employ upwards of 1000 workmen. Pop. 2794.

BACCHÆ, Βάκχαι, in *Antiquity*, the female companions of Bacchus, who are said to have followed him in his Eastern expedition. It was likewise the name given to the priestesses of Bacchus, who celebrated the *orgia* or mysteries of that god, and are sometimes designated by the names, Mænades, Thyiades, &c.

BACCHANALIA, festivals or orgies in honour of Bacchus, which were introduced by the Greeks of Southern Italy into Etruria and Rome. These festivals, which had been celebrated among the Greeks with great merriment, degenerated among the Romans into practices of hideous licentiousness and immorality, which were generally carried on at night and in secret. In the year B.C. 186 their existence was discovered by the Roman magistrates, and strict inquiries were instituted. The numerous crimes committed at these nocturnal orgies induced the senate to issue an order forbidding the celebration of the Bacchanalia both at Rome and in Italy. This order (*Senatus consultum de Bacchanalibus*), which is mentioned by Livy and Cicero, was discovered, in 1640, at Bari in Southern Italy, engraved upon a brazen table, from which it has frequently been copied, as in Drakenborch's edition of Livy, in Donaldson's *Varronianus*, and elsewhere.

The Greeks called the festivals of Bacchus *Dionysia Lenæa, Anthesteria*, which were celebrated at different seasons of the year, and at which the dramatic poets produced their new tragedies and comedies in the Dionysiac theatre in Athens. See Dr Schmitz's article *Dionysia* in Smith's *Dictionary of Greek and Roman Antiquities*. (L. S.)

Bacchiglione || Bacchus

BACCHIGLIONE, a river in the Venetian territory, which, rising in the mountains eastward of Trent, passes by Vicenza and Padua, and falls into the lagune of Venice below Este, after a course of 90 miles. It is navigable for large boats as far as Vicenza. It gave name to a province of Napoleon's Italian kingdom.

BACCHIUS (Βακχεῖος), surnamed the Old; a Greek author whose place and time of birth are unknown. He wrote an *Introduction to the Art of Music*, in the form of questions and answers, apparently intended for the use of schools. Its title, Εἰσαγωγὴ τέχνης μουσικῆς, might lead one to suppose that it contains some explanations of the art of composing or performing music; but it treats merely of sounds, intervals, systems, &c. Meibomius published the first part of Bacchius' work, with a Latin translation and notes, in his *Antiquæ Musicæ Auctores*, Amstel. 1652; but unaccountably omitted the second part, although he had a copy of it. In the royal library of Paris there exists a MS. copy of that second part, but it has not yet been published, except through a bad French translation of the whole work, given by Mersenne in his *Harmonie Universelle*, 1627. (G. F. G.)

BACCHUS (Βάκχος), the god of wine and revelry, more generally called Dionysus by the Greeks, was, according to the common tradition, the son of Jupiter and Semele the daughter of Cadmus and Hermione. When Semele was pregnant, Juno, in the disguise of a friend, persuaded her to urge the fatal request that her lover, in order to assure her of his divinity, would come to her embraces invested with the attributes of majesty. Jupiter, who had sworn by Styx to grant whatever she might ask, was obliged to comply; when the mortal Semele, unable to endure the fiery splendours of the god, was reduced to ashes. The infant Bacchus was snatched from the flames by Mercury, or by the nymph Dirce, and sealed up in his father's thigh until the full period of birth; whence he has received the epithet of Bimatris. Semele, under the name of Thyone, was immediately translated to heaven; or, as some report, she remained in Hades till brought thence by Bacchus. According to Ovid, the young Bacchus was brought up by his aunt Ino, and afterwards intrusted to the care of the nymphs of Mount Nysa. Others say that he was educated at Naxos by the nymphs Philia, Coronis, and Cleis. Pausanias relates a tradition of a more dramatic cast:—that when Cadmus discovered the amour of his daughter, he exposed her with her infant to the perils of the deep in a coffer or chest, which was carried by the waves to the coast of Brasiæ in Peloponnesus, where Semele was found dead, but the child still living. These various traditions appear to refer to different personages. Cicero enumerates five Dionysi: 1. The son of Jupiter and Semele; 2. the son of Nilus; 3. The son of Caprius or Cabirus; 4. The son of Jupiter and the Moon; 5. The son of Nisus and Thyone (*De Nat. Deor.* iii. 23). Bacchus is often confounded with the Egyptian Osiris, or the sun, whose worship appears to have been introduced into Greece by the Orphici; and when Bacchus is represented seated on a globe bespangled with stars, he must be regarded as identified with that deity. Tradition represents Bacchus as having assisted the gods in their war against the giants, in which he was cut to pieces; but this story evidently relates to Osiris, who was killed by his brother Typhon. When Bacchus was grown up he was afflicted by Juno with madness, in which condition he wandered over many parts of the earth. There is also a tradition that while he lay asleep in the isle of Naxos he was carried off by some Tyrrhenian mariners, whom he transformed into dol-

Bacchus.

phins, but spared the pilot because he had opposed their design. (See Acœtes.) In his celebrated expedition to India, he is represented sitting in a chariot drawn by a lion and tiger, with a panther's skin flung about his shoulders. His attendants were Pan, Silenus, and the Satyrs, besides a motley multitude including numerous Bacchantic women, who are variously styled Lenæ, Mænades, Thyades, Mimallones, Clodones, and Bassaræ or Bassarides. Armed with the thyrsus, and crowned with vine and ivy leaves, they danced around him with cups in their hands, shouting "Evohe! Bacche!" "Evohe! Eleleu!" to the sound of Phrygian flutes, drums, and cymbals. His progress was triumphant, and generally without bloodshed; for men gratefully acknowledged the divinity of the hero who taught them the cultivation of the vine and instructed them in the useful arts. He was relentless, however, towards those who opposed his authority; and on that account he inflicted dreadful punishments on Damascus, on Lycurgus the son of Dryas king of Thrace, and others.

Bacchus is generally represented as young, handsome, and beardless, with an air of luxurious languor and effeminacy, and long flowing hair, holding in his hand a thyrsus, and crowned with vine or ivy leaves. Sometimes he has the appearance of age and decrepitude, as indicating the effects of intemperance: at other times he is seen as an infant in the arms of his foster-father Silenus, or riding on the shoulders of Pan, or on a goat, and accompanied by goats and satyrs. The horns with which he is sometimes represented are probably the symbol of victory or dominion, according to the Egyptian idea; but these are generally short, and concealed almost entirely by the hair. The phallus, which had a conspicuous place in the processions of Bacchus, was introduced from Egypt by Melampus. (See Herodot. ii. 49.) His several appellations of Liber, Bromius, Evan, Thyonæus, Bassareus, Psilas, &c., were derived either from circumstances connected with his personal history, from the places where he was worshipped, or from the ceremonies observed at his festivals. These festivals, which were very numerous, were called Orgia, Dionysia, Bacchanalia, &c. The orgies were celebrated by night, and those held on Mount Cithæron were especially noted for extravagance and licentiousness. The Dionysia at Athens were celebrated with extraordinary splendour. The rites of Bacchus were often attended with the grossest debauchery; and to such a pitch was this depravity carried at Rome, that it was found necessary to suppress the orgies by a decree of the senate. The vine, ivy, laurel, yew, fig-tree, and fir, were sacred to Bacchus; as were also the tiger, panther, ass, dolphin, magpie, and serpent; the last, as emblematic of immortality, being common to several of the gods. The ram was sacrificed to him, as was also the goat, on account of its destructiveness to vines. (See Ascolia.) It is said that in very early times this deity was propitiated with the blood of human victims; and even Themistocles had the barbarity to sacrifice three noble Persian youths on an altar which he erected to Bacchus Omestes on board his galley. (Plutarch, *Themist.*) Bacchus had numerous children by Ariadne, whom he espoused in the island of Naxos, after her desertion by Theseus. (See Ariadne.) The most interesting circumstance in connection with the worship of this deity is that of the dithyrambics and mummeries performed at the celebration of his mysteries, which were undoubtedly the first rude prototypes of scenic or theatrical representations, as eventually developed in the comedies of Cratinus, Eupolis, and Aristophanes. Tragedy also arose out of the worship of Bacchus. The worshippers, clad in the skins of goats and fawns, imitated the poetical fictions concerning the god; personating Silenus, Pan, the nymphs and satyrs, and arrayed in grotesque dresses, they smeared their faces with the lees of wine, and diverted themselves and others with their antic gestures and comic sallies.

The Greek word τραγῳδία, *tragedy*, is generally admitted to have been derived from the name of the victim, τράγος, *a goat*, which was sacrificed on these occasions, accompanied with the singing of an ode or hymn, ᾠδή.

Bacchylides || Baccio.

The origin of Bacchus and of his name have given rise to a diversity of opinions. The name has been deduced from ἰάχω, and from βοάω, because of the noise which prevailed at the celebration of his rites. Diodorus mentions three deities of this name: 1. The conqueror of India, who is known as the bearded Bacchus; 2. The horned Bacchus, son of Jupiter and Proserpine; 3. The son of Semele, called the Bacchus of Thebes. The ingenious Rudbeck conjectures that Bacchus was a Scythian or Thracian hero named Bagge, whom tradition represents as the conqueror of the Eastern world; and this name he derives from *bagge, book, i.e.* a goat or ram, metaphorically taken for *dux*. (*Atlantic.* ii. p. 146.) Ovid, indeed, makes Bacchus set out from the Hebrus, a river of Thrace:—

Ibat arenoso satyris comitatus ab Hebro.—*Fast.* iii. 737.

The worship of this deity appears to have been of Eastern origin. The name Dionysus (Διόνυσος) is apparently a compound of Διὸς and Νύσα, *i.e.* the deity from Nysa, which was the name of a mountain and city between the rivers Choaspes and Cophes; yet it should be observed that this name was borne by several other places in different parts of the world. (T. S. T—L.)

BACCHYLIDES, Βακχυλίδης, a famous Greek lyric poet, born at Iulis in Ceos, was the nephew of Simonides, and flourished about 470 years before Christ. He resided long at the court of Hiero of Syracuse with Simonides and Pindar, and wrote odes, hymns, and epigrams, of which some fragments are published in the first volume of Brunck's *Analecta*; by Neue, *Bacchylidis Cei Fragm.*; and by Bergk, *Poëtæ Lyrici Græci.*

BACCIO, or Baccius, Andrea, a celebrated physician of the sixteenth century, born at St Elpideo. He practised physic at Rome with great reputation, and was first physician to Pope Sixtus V. The most scarce and valuable of his works are the following:—1. *De Thermis*; 2. *De Naturali Vinorum Historia, de Vinis Italiæ, et de Conviviis Antiquorum*; 3. *De Venenis et Antidotis*; 4. *De Gemmis ac Lapidibus Pretiosis.*

Baccio *della Porta*, called *Bartolomeo di S. Marco*, a celebrated historical and portrait painter, was born at Savignano, near Florence, in 1469, and died in 1517. He was a disciple of Cosimo Roselli; but his principal knowledge of the art was derived from Lionardo da Vinci. He understood the true principles of design better than most masters of his time; and as he was a considerable master of perspective, Raphael had recourse to him after quitting the school of Perugino, and under his direction studied the art of managing and uniting colours, as well as the rules of perspective. Some years after the departure of Raphael from Florence, Baccio visited Rome, where he derived much benefit from the study of the antique, and of the works of Raphael, which were then the admiration of the whole world. His improvement was manifested in a picture of St Sebastian, which he finished on his return to Florence. This was so well designed, so naturally and beautifully coloured, and so strongly expressive of suffering and agony, that it was found necessary to remove it from the place where it had been exhibited in the chapel of a convent, in consequence of the too powerful impression it had made on the imaginations of many women who beheld it. Baccio was very laborious, and made nature his perpetual study; his designs were distinguished for correctness and purity, his figures had a great deal of grace, and his colouring was admirable. He is usually accounted the inventor of the useful contrivance called the *lay figure*. There is a capital picture of the Ascension, by Baccio, in the Florentine collection.

Bach || Bachian.

BACH, JOHANN SEBASTIAN, a most original and learned composer of music, was born at Eisenach, March 21, 1685, and died at Leipzig, July 30, 1750. His works were very numerous, but many of them have been lost, and many others still remain in manuscript; although, fortunately, a number of his best works have been printed. His published works alone prove his powers of invention and construction to have been prodigious. His compositions consist chiefly of sacred music, and pieces for the organ and harpsichord. He composed no dramatic music. Many persons believe that Gluck was the first great German composer of recitatives; but this error is made evident by Bach's *Grosse Passionsmusik*, published in score, at Berlin, in 1830. In knowledge of instrumentation and instrumental effects, he was far in advance of his contemporaries. As a fugue writer and an extempore composer, he was unequalled; while as an organ and harpsichord player he had no rival but Handel. What he wrote was to please himself and not the public, whose favour he never courted. He was twice married, and had eleven sons and nine daughters. All his sons became professional musicians, but only three or four of them distinguished themselves as composers. (G. F. G.)

BACH, *Carl Philip Emanuel*, the second son of Johann Sebastian Bach, was by far the most remarkable of the eleven brothers, not only for his peculiar genius and originality, but also for the great influence which his compositions exercised on the forms and style of later instrumental music. His style, full of novelty and elegance, was that which Haydn and Mozart studied attentively, and carried to perfection by giving it greater breadth of development. He was born at Weimar on the 14th of March 1714, and died at Hamburg on the 14th of December 1788. His compositions, vocal and instrumental, are numerous. Many of them are still unpublished. (G. F. G.)

BACHELOR, a common term for a man not married, or who is yet in a state of celibacy. The Roman censors frequently imposed fines on bachelors. Dionysius of Halicarnassus mentions an old constitution, by which all persons of full age were obliged to marry. But the most celebrated law of this kind was that made under Augustus, called the *Lex Julia de Maritandis Ordinibus*, by which bachelors were made incapable of taking legacies or inheritances by will, unless from their near relations. By the laws of Lycurgus bachelors were branded with infamy, and excluded from all offices civil and military, and even from the public entertainments. At certain feasts they were exposed to public derision, and led round the market-place. In the canon law we find injunctions on bachelors, either to marry, or to turn monks and profess chastity in earnest.

BACHELOR was anciently applied to those who had attained to knighthood, but wanted the number of vassals sufficient to entitle them to have their banner carried before them in the field of battle; or who, being of the order of bannerets, were not yet of age to display their own banner, and consequently obliged to march to battle under the banner of another. Bachelor was also a title given to young cavaliers, who having made their first campaign, received the military girdle accordingly; and it further served to distinguish him who had overcome an adversary in a tournament the first time he had ever engaged.

Knights-BACHELORS, the most ancient, but the lowest, order of knights in England, known by the name of *knights* only. They are styled *knights-bachelors*, either, according to some, as denoting their degree, *quasi* "*bas chevaliers*;" or, according to others, because this title does not descend to their posterity. Knights are called in Latin *equites aurati*, from their wearing gilt spurs.

BACHELORS *of Arts*, *of Divinity*, *of Laws*, and *of Medicine*, are persons who have taken the first degree in these respective faculties. See UNIVERSITIES.

BACHIAN, one of the Molucca islands, about fifty-four miles in length by twenty in breadth, and separated by a narrow strait from the island of Gilolo. It yields gold dust, sago, fruits, and cloves. The inhabitants are Malay Mahometans. Long. 127. 33. E. Lat. 1. 0. S.

Bacillaria || Back-gammon.

BACILLARIA, one of Ehrenberg's families of infusoria, containing 30 genera or more. The siliceous bucklers of those minute animals form whole beds of the *polishing-slate* of Bohemia; and are contained in astonishing numbers in the cretaceous formations of England, Germany, Italy, Greece, and North America. See ANIMALCULE.

BACKER, or BAKKER, *Jacob*, portrait and historical painter, was born at Harlingen in 1609, but spent the greater part of his life at Amsterdam. His portraits are executed with boldness, spirit, and grace. His incredible expedition in painting was testified by a half-length portrait of a lady, adorned with rich drapery and jewels, which he began and finished in one day. Of his historical subjects the picture of Cimon and Iphigenia is worthy of mention. He died in 1651.

BACKERGUNGE, one of the lower provinces of the presidency of Bengal, situate in the delta of the Ganges, and containing an area of 3794 square miles, with a population of 733,800. The tract throughout is low, level, and intersected by numerous rivers, the principal of which are the Ganges and the Meghna. For the most part the soil is alluvial, but notwithstanding the inundations to which the district is subject, the climate is more healthy than in most parts of Bengal, the several channels serving as drains to carry off the stagnant water immediately after the cessation of the rains. Generally speaking the country is well cultivated, and the crops of rice are rich in the extreme. The town of Backergunge was formerly the principal place of the province, but the seat of the civil establishment was some time since transferred to Burrisol, a town 128 miles east of Calcutta, in Lat. 22. 43. Long. 90. 23. (E. T.)

BACKGAMMON, an ingenious game played with dice upon a table by two persons. The table is divided into two parts, upon which there are twenty-four black and white spaces, called *points*. Each player has fifteen men, black and white, to distinguish them, and they are disposed of in the following manner: Supposing the game to be played in the right-hand table, two are placed upon the ace point in the adversary's table, five upon the six point in the opposite table, three upon the cinque point in the hithermost table, and five on the six point in the right-hand table. The grand object in this game is for each player to bring the men round into his right-hand table, by throwing with a pair of dice those throws that contribute towards it, and at the same time to prevent his adversary doing the like. The first best throw upon the dice is esteemed aces, because it stops the six point in the outer table, and secures the cinque in the thrower's table; so that the adversary's two men upon the thrower's ace point cannot get out with either quatre, cinque, or six. This throw is an advantage often given to the antagonist by the superior player. When he carries his men home in order to lose no point, he is to carry the most distant man to his adversary's bar point, that being the first stage he is to place it on; the next is six points farther, viz. in the place where the adversary's five men are first placed out of his tables; and he must go on in this method till all his men are brought home except two, when by losing a point he may often save the gammon, by throwing two fours or two fives. When a hit is only played for, he should endeavour to gain either his own or adversary's cinque point; and if that fail by his being hit by the adversary, and he find him farther advanced than himself, in that case he must throw more men into the adversary's tables, which is done in this manner: He must put a man upon his cinque or bar point; and if the adversary neglect to hit it, he may then gain a forward game instead of a back game. But if the adversary hit him, he should play for a back game; and then the greater number of men

Back-gammon.

which are taken up makes his game the better, because by these means he will preserve his game at home. He should then endeavour to gain both his adversary's ace and trois points, or his ace and deuce points, and take care to keep three men upon the adversary's ace point, that in case the latter hit him from thence, that point may remain still secure to himself. A back game should not be played for at the beginning of a set, because it would be a great disadvantage, the player running the risk of a gammon to win a single hit. The subsequent calculations will show the odds of entering a single man upon any certain number of points. Upon two dice there are thirty-six chances, and upon these chances the following points, viz.

	Points.
2 Aces	4
2 Deuces	8
2 Trois	12
2 Fours	16
2 Fives	20
2 Sixes	24
6 and 5 twice	22
6 and 4 twice	20
6 and 3 twice	18
6 and 2 twice	16
6 and 1 twice	14
5 and 4 twice	18
5 and 3 twice	16
5 and 2 twice	14
5 and 1 twice	12
4 and 3 twice	14
4 and 2 twice	1
4 and 1 twice	10
3 and 2 twice	10
3 and 1 twice	8
2 and 1 twice	6

Divide by 36)294(8

This proves, that upon an average the player has a right to 8 points each throw 6

The chances upon two dice calculated for backgammon are as follow:—

2 Sixes	1
2 Fives	1
2 Fours	1
2 Trois	1
2 Deuces	1
†2 Aces	1
6 and 5 twice	2
6 and 4 twice	2
6 and 3 twice	2
6 and 2 twice	2
†6 and 1 twice	2
5 and 4 twice	2
5 and 3 twice	2
5 and 2 twice	2
†5 and 1 twice	2
4 and 3 twice	2
4 and 2 twice	2
†4 and 1 twice	2
3 and 2 twice	2
†3 and 1 twice	2
†2 and 1 twice	2
	36

As it may seem difficult to find out by this table of thirty-six chances what are the odds of being hit upon a certain or flat die, let the following method be pursued. The player may observe in the table that the chances marked thus † are,

† 2 aces	1
† 6 and 1 twice	2
† 5 and 1 twice	2
† 4 and 1 twice	2
† 3 and 1 twice	2
† 2 and 1 twice	2
Total,	—11
When deducted from	36
There remains	25

From which it appears that it is 25 to 11 against hitting an ace upon a certain or flat die. And this method holds good with respect to any other flat die. For example, what are the odds of entering a man upon 1, 2, 3, 4, or 5 points? Answer.

To enter it upon	for	against	for	agt.
1 point is	11	to 25 or about	4	to 9
2	20	... 16	5	... 4
3	27	... 9	3	... 1
4	32	... 4	8	... 1
5	35	... 1	35	... 1

The following table shows the odds of hitting with any chance in the reach of a single die:—

To hit upon	for	against	for	agt.
1 is	11	to 25 or about	4	to 9
2 ...	12	... 24	1	... 2
3 ...	14	... 22	2	... 3
4 ...	15	... 21	5	... 7
5 ...	15	... 21	5	... 7
6 ...	17	... 19	8½	... 9½

The odds of hitting with double dice are as follow:— Back-gammon.

To hit upon	for	against	for	agt.
7 is	6	to 30 or about	1	to 5
8 ...	6	... 30	1	... 5
9 ...	5	... 31	1	... 6
10 ...	3	... 33	1	... 11
11 ...	2	... 34	1	... 17
12 ...	1	... 36	1	... 35

How to find out the odds of being hit upon a six by the table of thirty-six chances.

2 Sixes	1
2 Trois	1
2 Deuces	1
6 and 5 twice	2
6 and 4 twice	2
6 and 3 twice	2
6 and 2 twice	2
6 and 1 twice	2
5 and 1 twice	2
4 and 2 twice	2
	—17
Which deducted from	36
There remains	19

By which it appears to be 19 to 17 against being upon a six.

The odds on the hits.

2 love is about	5 to 2
2 to 1 is	2 to 1
1 love is	3 to 2

If a player has taken up two of the adversary's men, and happen to have two, three, or more points made in his own tables, he should spread his men, that he may either take a new point in his tables, or be ready to hit the man which the adversary may happen to enter. If he find, upon the adversary's entering, that the game is upon a par, or that the advantage is on his own side, he should take the adversary's man up whenever he can, it being 25 to 11 that he is not hit; except when he is playing for a single hit only, because then, if playing the throw otherwise gives him a better chance for it, he ought to do it.

It being five to one against his being hit with double dice, he should never be deterred from taking up any one man of the adversary's.

If he has taken up one of the adversary's men, and happen to have five points in his own tables, yet is forced to leave a blot out of his tables, he should endeavour to leave it upon doublets in preference to any other chance, because in that case the odds are 35 to 1 that he is not hit; whereas it is only 17 to 1 that he is hit upon any other chance.

When the adversary is very forward, a player should never move a man from his own quatre, trois, or deuce points, thinking to bear that man from the point where he put it, as nothing but high doublets can give him any chance for the hit. Instead of playing an ace or a deuce from any of those points, he should play them from his own six or highest points, so that, throwing two fives or two fours, his six and cinque points being eased, would be a considerable advantage to him; whereas if they had been loaded he would have been obliged to play otherwise.

It is the interest of the adversary to take up the player as soon as he enters. The blot should be left upon the adversary's lowest point; that is to say, upon his deuce point rather than upon his trois point, or upon his trois point rather than his quatre point, or upon his quatre point preferably to his cinque point, for a reason before mentioned. All the men the adversary plays upon his trois or his deuce point are deemed lost, being greatly out of play; so that those men not having it in their power to make his cinque point, and his game being crowded in one place and open in another, the adversary must be greatly annoyed by the player.

Back-gammon.

If the player have two of the adversary's men in his tables, he has a better chance for a hit than if he had more, provided his game is more forward than that of his antagonist; for if he had three or more of the adversary's men in his tables, he would stand a worse chance to be hit.

When a player is running to save the gammon, if he should have two men upon his ace point and several men abroad, although he should lose a point or two in putting his men into his tables, it is his interest to leave a man upon the adversary's ace point, because it will prevent his adversary from bearing his men to the greatest advantage, and at the same time the player will have a chance of the adversary's making a blot, which he may chance to hit. However, if a player find upon a throw that he has a probability or saving his gammon, he should never wait for a blot, as the odds are greatly against his hitting it, but at once embrace that opportunity to escape.

Suppose the adversary has so many men abroad as to require three throws to put them into his tables, and at the same time that the player's tables are made up, and that he has taken up one of the adversary's men; in this case it is about an equal wager that the adversary is gammoned; for in all probability the player has borne two men before he opens his tables, and when he bears the third man he will be obliged to open his six or cinque point. It is then probable that the adversary is obliged to throw twice before he enters his men in the player's tables, twice more before he puts that man into his own tables, and three throws more to put the men which are abroad into his own tables; in all seven throws. Now the player having twelve men to bear, he may be forced to make an ace or a deuce twice before he can bear all his men, and consequently will require seven throws in bearing them; so that, upon the whole, it is about equal whether the adversary is gammoned or not.

Suppose a player has three men upon his adversary's ace point and five points in his own tables, and that the adversary has all his men in his tables, three upon each of his five highest points; has the player a probability of gammoning his adversary or not?

	Points.
For bearing three men from his 6th point is	18
From his 5th point	15
From his 4th point	12
From his 3d point	9
From his 2d point	6
In all,	—60
Bringing his three men from the adversary's ace point to his six point in his own tables, being 18 points each, and making together	54
There must remain	6

From which it is plain that the player has much the best of the probability of the gammon; exclusive of one or more blots which the adversary is liable to make in bearing his men, and supposing at the same time the throws to be upon an equality. But suppose two blots are left, either of which cannot be hit but by double dice; one must be hit by throwing eight, and the other by throwing nine; so that the adversary has only one die to hit either of them. What, then, are the odds of hitting either of them?

The chances of two dice being in all	36
The chances to hit 8 or 6 and 2 twice	2
5 and 3 twice	2
2 deuces	1
2 fours	1
The chances to hit 9 or 6 and 3 twice	2
5 and 4 twice	2
2 trois	1
For hitting in all	11
Chances for not hitting remain	25

So that the odds are 25 to 11 against hitting either of these blots.

Backhuysen || Bacon.

This method may be taken to find out the odds of hitting three, four, or five blots upon double dice, or blots made upon double and single dice at the same time. After knowing how many chances there are to hit any of these blots, they must be added all together, and then subtracted from the number 36, which are the chances of the two dice.

The laws of backgammon are as follow: 1. When a man is taken from any point, it must be played; when two men are taken from it, they also must be played. 2. A man is not supposed to be played till it is placed upon a point and quitted. 3. If a player have only fourteen men in play, there is no penalty inflicted, because by his playing with a lesser number than he is entitled to, he plays to a disadvantage for want of the deficient man to make up his tables. 4. If he bear any number of men before he has entered a man taken up, and which of course he was obliged to enter, such men so borne must be entered again in the adversary's tables as well as the man taken up. 5. If he have mistaken his throw and played it, and his adversary have thrown, it is not in the choice of either of the players to alter it, unless they both agree so to do.

BACKHUYSEN, Ludolf, an eminent painter of the Dutch school, born at Embden in Hanover in 1631; died in 1709. He was brought up as a merchant at Amsterdam, but early discovered a genius for painting. Such was his zeal for the art, that he frequently exposed himself on the sea in an open boat, in order to study the effects of tempests on that element. His sea-pieces are greatly esteemed.

BACK-RENT, in Scotland, is rent paid by a tenant after reaping the crop, in contradistinction to *fore-rent*, or rent payable previous to the reaping of the first crop; which is settled in either case by the terms of the lease.

BACK-STAFF, or Davis's Quadrant, an instrument invented by Captain John Davis, about the year 1590, for taking the sun's altitude at sea; but now superseded by Hadley's quadrant. It consisted of two concentric arcs and three vanes, the arc of the longer radius being 30 degrees, and that of the shorter 60 degrees, thus making altogether 90 degrees, or a quadrant. It derived its name from the observer's standing with his back to the sun.

BACON, Francis, Viscount St Albans, and Baron Verulam. This illustrious man was born in London, on the 22d day of January 1561. His father, Sir Nicholas Bacon, a courtier, a lawyer, and a man of erudition, stood high in the favour of Queen Elizabeth, and was lord-keeper during twenty years of her reign. Anne, the second wife of Sir Nicholas, and the philosopher's mother, was the daughter of Sir Anthony Cooke, Edward the Sixth's tutor, and was herself distinguished among the learned females of the time. One of her sisters became the wife of Elizabeth's celebrated treasurer, Lord Burleigh. Delicate in health, and devoted to sedentary employment, Francis Bacon exhibited in early boyhood the dawning of those powers whose versatility afterwards became not less remarkable than their strength. As a child he delighted the queen with his precocious gravity and readiness of speech; and before he had completed his twelfth year we see him investigating the cause of a singular echo in a conduit, and endeavouring to penetrate the mystery of a juggler who performed in his father's house. At the age of thirteen he was matriculated at Trinity College, Cambridge, of which Whitgift was then master; but his residence at the university lasted scarcely three years, and his writings contain many expressions of dissatisfaction with the current system of academical education. In his sixteenth year he was sent abroad, and lived for some time at Paris, under the charge of the English ambassador, Sir Amias Paulett; after which he visited the French provinces, and added to his literary and philosophical studies an acquaintance with foreign policy and statistics, the fruit of which soon appeared in his tract upon the State of Europe. In February 1580, his father died, and he immediately returned to England.

Bacon. Sir Nicholas left but a scanty fortune; and his son Francis, the youngest of a large family, found himself obliged, in his twentieth year, to devise the means of earning a livelihood. It might have been thought that friends could not have been wanting to one who, besides his own acknowledged merit, had it in his power to urge the long and honourable services of his father, while his uncle was the prime minister of the kingdom. Of the patronage which thus seemed to be at his command, Bacon attempted to avail himself, desiring to obtain such a public employment as might enable him to unite political activity in some degree with literary study. But his suit was received neglectfully by the queen, and harshly repulsed by his kinsman. Although all the causes of this conduct may not be discoverable, a few lie at the surface. The lord-keeper had, in the later years of his life, lost the royal favour. Burleigh, besides his notorious contempt for men of letters, had to provide for sons of his own, to whom their accomplished cousin might have proved a dangerous rival. From the Cecils, indeed, Bacon never derived any efficient aid, till he had forced his way upwards in spite of them; and there are evident traces of jealousy and dislike in the mode in which he was treated both by the old treasurer, and by his second son, Robert.

Obliged therefore to betake himself to the law, Bacon was admitted at Gray's Inn, where he spent several years obscurely in the study of his profession, but with increasing practice at the bar. The friendship of his fellow lawyers, earned by his amiable disposition and his activity in the affairs of the society, bestowed on him offices in his inn of court; but his kinsmen were still cold and haughty. Lord Burleigh continued to write him letters of reproof; and Robert Cecil, already a rising statesman, sneered at speculative intellects, and insinuated their unfitness for the business of life. In 1590, when Bacon was in his thirtieth year, he was visited for the first time with court-favour, receiving then an honorary appointment as queen's counsel extraordinary; and to this was added a grant of the reversion of a clerkship in the star-chamber, which did not become vacant for eighteen years. But the lawyer's heart was not in his task. His brilliant professional success, and the awakening friendship of his relations, merely suggested to him renewed attempts to escape from the drudgery of the bar. His views are nobly expressed in a letter which he addressed to the lord-treasurer the year after his appointment.[1] We linger with melancholy pleasure over these abortive efforts made by one of the finest and most capacious of intellects to extricate itself from that labyrinth of worldly turmoil, in which its owner was destined to purchase rank and splendour at the expense of moral degradation and final ruin.

We are henceforth to behold Bacon actively engaged in political life, as well as in the duties of his profession. Two parties then divided the court, equally remarkable in different ways on account of those who headed them. Burleigh was the chief of the queen's old counsellors, on whom, amidst all her caprices, she always had the prudence to rely for the real business of the state: the young and gay, those who aspired to be ranked as the personal friends or adorers of the withered sovereign of hearts, were led by the high-spirited and imprudent Earl of Essex. To the party of this nobleman Bacon decidedly attached himself, and soon indeed shared with his own elder brother Anthony, the earl's most private confidence. Valuable advisers were they to their rash patron; and a valuable servant of the nation did Francis Bacon bid fair to become, when, in November 1592, he entered parliament as one of the knights of the shire for Middlesex. His first speech, in February following, contained an urgent pleading for improvements in the law; in another address, delivered in March, he resisted, with exceeding boldness as well as force of reason, the immediate levying of an unpopular subsidy to which the House had already consented. The young lawyer's exposition of unpleasant truths gave deep offence to the queen. His uncle and the lord-keeper were both commissioned to convey to him the assurance of the royal displeasure; and the two humble, nay, crouching letters of apology, still extant, in which he entreated those ministers to procure his pardon, did not forebode much independence in his subsequent conduct. We do not, indeed, again hear Bacon named as a champion of popular rights. Bacon.

In the year 1594, Sir Edward Coke being made attorney-general, the solicitorship became vacant; and Bacon's application for the office was strenuously supported by Essex. But all efforts were in vain. The powerful kinsmen were colder than ever towards one who had chosen another patron. The lord-keeper, Puckering, acted in a manner which drew on him a spirited rebuke from the candidate. The queen hesitated, coquetted, told Essex that his friend, though witty, eloquent, and in some branches learned, was a showy lawyer rather than a profound one. After a delay of many months, the place was given to a plodding serjeant; and Bacon's generous patron, vexed at the disappointment of his hopes, sought to console both him and himself by a gift equally munificent and delicate. Bacon received from him an estate at Twickenham, worth about eighteen hundred pounds. The present, in all likelihood, came very seasonably; for he appears to have been already involved in those pecuniary embarrassments from which he was never afterwards completely able to extricate himself. He was obliged to sell the land which Essex had given him; two years later he was arrested in the street for a debt of three hundred pounds; and among the Lord Chancellor Ellesmere's papers, recently published, there is a curious acknowledgment, granted in 1604, for a pledge in security of an advance of fifty pounds to him. These reasons offer the only apology for the addresses which, about the time of his arrest, he paid to a wealthy and shrewish widow, who, fortunately for him, preferred his professional brother and personal enemy, Sir Edward Coke. In the meantime, his legal reputation continued to increase, and his parliamentary exertions were unremitted, though altogether free from that independence which had once characterized them. We thus trace Bacon down to his thirty-

[1] "I wax now somewhat ancient: one-and-thirty years is a great deal of sand in the hour-glass. My health, I thank God, I find confirmed, and I do not fear that action shall impair it; because I account my ordinary course of study and meditation to be more painful than most parts of action are. I ever bear a mind, in some middle place that I could discharge, to serve her majesty; not as a man born under Sol that loveth honour, nor under Jupiter that loveth business, for the contemplative planet carrieth me away wholly; but as a man born under an excellent sovereign, that deserveth the dedication of all men's abilities. . . . Again, the meanness of my estate doth somewhat move me; for, though I cannot accuse myself that I am either prodigal or slothful, yet my health is not to spend, nor my course to get. Lastly, I confess that I have as vast contemplative ends, as I have moderate civil ends; *for I have taken all knowledge to be my province;* and, if I could purge it of two sorts of rovers,—whereof the one with frivolous disputations, confutations, and verbosities, the other with blind experiments, and auricular traditions and impostures, have committed so many spoils,—I hope I should bring in industrious observations, grounded conclusions, and profitable inventions and discoveries; the best state of that province. This, whether it be curiosity, or vain-glory, or nature, or (if one take it more favourably) philanthropia, is so fixed in my mind, as it cannot be removed. . . . *And if your lordship will not carry me on,* I will not do as Anaxagoras did, who reduced himself with contemplation into voluntary poverty: but *this I will do,—I will sell the inheritance that I have, and purchase some lease of quick revenue, or some office of gain, that shall be executed by deputy; and so give over all care of service, and become some sorry bookmaker, or a true pioneer in that mine of truth, which, he said, lay so deep.*"—(Cabula, p. 18. Bacon's Works, vol. xii. p. 6, 7. Montagu's edit.)

Bacon. ninth year, pausing only to remark, that two years earlier, that is, in 1597, his celebrated Essays were first published. Although merely the skeleton of what they afterwards became, these compositions gained high reputation for their author, not only at home, but also on the continent.

After this, the first step in Bacon's literary career, we approach what is the most painful task of his biographer, a dark page of his history, over which no ingenuity has ever been able to throw a veil thick enough to disguise its foulness. We have seen him the friend, the adviser, the grateful vassal of Essex; we are now to behold him deserting his benefactor, assisting to destroy him, standing forth in the face of the world as his enemy and accuser. The philosopher's latest biographer has pronounced his conduct in this matter to be honourable and praiseworthy; and to his pages we must refer those who are curious to canvass arguments of which we are ourselves unable to discover the force. Bacon, unfortunately for himself, had lately risen much in royal favour, and been greatly trusted and employed. Accordingly, in the first stages of Essex's decline, he had to act a double part,—now offering to his patron advices which were but seldom followed, now seeking excuses to pacify the queen's rising displeasure. His natural inclination for temporizing, the success which had hitherto attended his cautious policy, the honest wish to serve his generous friend,—all these reasons may have concurred in tempting him to embark in the dangerous channel. But the sunken rocks soon encompassed him, and shipwreck was unavoidable. Alienation either from Elizabeth or from Essex speedily appeared to be the necessary result of the position into which the parties were coming. Bacon had not the courage to take the nobler part, and place himself by the side of his falling friend, at the probable expense of all his worldly prospects. Suspicion and estrangement soon took the place of affectionate confidence; and the trust reposed in him by the queen was purchased by the bitter consciousness that Essex regarded him as treacherous and hostile. A more degrading task was yet to come The first trial of the earl, in reference to his conduct in Ireland, was determined upon; and Bacon's enemies asserted that he offered himself to act as one of the counsel for the prosecution. In that memoir in defence of his conduct which he wrote in the next reign, and which proves satisfactorily nothing but his own humiliating consciousness of guilt, he states as to this matter what was doubtless the truth. It had been resolved that the proceedings against the rash earl should not be carried out to his destruction, but should only disarm and discourage him; and, a hint being conveyed to Bacon that the queen had not determined whether he should be employed professionally in the affair or not, he thought proper to address to her "two or three words of compliment," intimating that if she would dispense with his services he would consider it as one of her greatest favours, but that otherwise he knew his duty, and would not allow any private obligations to interfere with what he owed to her majesty. All this was, he adds, "a respect no man that had his wits could have omitted." Bacon, in short, still wished to serve two masters; but he had now placed himself at the mercy of those from whom he had no forbearance to expect. The queen, suspicious and moody, was jealous of his attachment to Essex, and bent on compelling him to do her service unreservedly: her advisers, or some of them, were glad to have the odium of the earl's destruction shared with them by one so distinguished, who had, likewise, been the victim's friend. It was intimated that Bacon's services could not be dispensed with; but he tells us, (and he probably repeats only what his masters tried to make him believe), that it was resolved his share in the prosecution should be confined to matters which could not do his unfortunate patron any serious harm. Essex's private censure by the privy-council followed; and, while he was committed to custody-at-large, Bacon incurred, by his appearance against him, an obloquy of which his letters show him to have been painfully sensible. In a few months the earl's open rebellion took place; he was seized, and put upon his trial in February 1601, along with Lord Southampton; and on this occasion, when his life was at stake, Bacon again appeared as one of the counsel for the prosecution, and delivered a speech of which there is extant an imperfect account. The language is harsh, but less so than addresses of the kind used to be in those days. The topics are oratorical, and, as it has been justly remarked, are less calculated for ensuring conviction (which indeed was certain) than for placing the conduct of the prisoner in an odious light, and hardening the queen's heart against him; and, although it would be rash to judge of the real temper of the harangue without knowing more of its contents, yet what we possess contains much that cannot possibly be explained so as to do credit to the speaker. We know, likewise, how the object of the attack received it. At one place Essex interrupted his treacherous friend, and called upon him to say, as a witness, whether he had not, in their confidential intercourse, admitted the truth of those excuses which he now affected to treat as frivolous and false. Essex was convicted; and between his sentence and execution, Bacon admits in his exculpatory memoir that he made no attempt to save him; seeing the queen but once, as he says, and on that occasion venturing to do nothing further than pronouncing a few common-places on the blessed uses of mercy. But not even here was the disgrace to end, in which the timid man of the world had steeped himself. The act which had cost Elizabeth's own heart so much, had also made her unpopular; a defence of the royal policy in regard to Essex was thought necessary, and the pen that drew it up, under the direction of the queen's advisers, was, we are grieved to find, no other than Bacon's. The "Declaration of the Practices and Treasons attempted and committed by Robert Earl of Essex," was printed, and is extant: "a performance," says a late writer, "in defence of which, in the succeeding reign, Bacon had not a word to say; a performance abounding in expressions which no generous enemy would have employed respecting a man who had so dearly expiated his offences." With this humiliating act of service we may consider Bacon's public life under Elizabeth as closed.

Bacon.

The reign of her successor was, from its commencement, a more auspicious era for men of letters and philosophy, with whom James, amidst all his imbecility and cold-heartedness, was not by any means ill fitted to sympathise. Bacon's learning was no longer open to sneers and contempt; his uncle was dead; his hunchback cousin, Robert Cecil, who soon became Earl of Salisbury, was kept in check by his hereditary prudence; and Coke, who had insulted our philosophic lawyer grossly, as he insulted every one who was defenceless and within his reach, was in a few years removed to the head of the court of common pleas. From the first hour of James's reign, Bacon lost no opportunity of recommending himself to favour; but the first mark of it which he received, was one of which he neither was nor could have been proud, and which, nevertheless, he thought proper to solicit. When the king called upon all persons possessing forty pounds a year in land to be knighted, or to compound for a dispensation from the honour, one effect of this scheme for filling the royal coffers was, that three members of Bacon's mess at Gray's Inn appeared among the new knights. That love of external distinctions which was the fatal weakness of his nature, was called into play, and the philosopher was disconcerted by the titles of his companions, beside whom he sat untitled. At the same time, likewise, he had, in his own words, "found out an alderman's daughter, a handsome maiden, to his liking;" and the alderman's daughter was likely to be more easily won if her admirer could offer her

Bacon. a showy accession of rank. Accordingly, Bacon wrote to his cousin Cecil, stating his desire to obtain, for these reasons, "this divulged and almost prostituted title of knighthood." The request was granted, but was immediately followed by another. Bacon, heartily ashamed of the company in which he was to appear, entreated that he might be knighted alone; "that," as he says, "the manner might be such as might grace one, since the matter will not." This petition was refused; and, on the day of the coronation, Francis Bacon was one of three hundred who received the empty honour. Soon afterwards, being forty-two years old, he was married to the alderman's daughter, Alice Barnham, who brought him a considerable fortune, but seems, in the latter part of his life at all events, to have contributed little to his domestic happiness.

These details are in themselves trifles; but they are strange illustrations of the mixed character of one who, while thus soliciting honours of which he was half-ashamed, and eager for public distinctions, which, though more solid, were likewise more dangerous, was not only respected and distinguished as a lawyer and a statesman, as an orator, a scholar, and an author, but was occupied, during his few hours of leisure, in completing the most valuable system of philosophy that had ever been expounded in modern Europe. Smaller compositions, submitted to his friends, showed from time to time the progress of the great work which he had marked out as the business of his life; and among these was the treatise on the Advancement of Learning, published in 1605, in its author's forty-fifth year. Political tracts alternated with these philosophical speculations.

In the mean time his public reputation, and his favour with the king, increased and kept pace with each other. In parliament he was actively useful in forwarding favourite and really good measures of the court, such as the union of England and Scotland, and the proposed consolidation of the laws of the countries. Nor was he less usefully employed in taking a prominent part in the select committee of the house upon grievances: and in his skilful hands, the report became all that the rulers could have wished, without exciting any general feeling against the framers. In 1604, he was made king's counsel in ordinary, with a salary of forty pounds, to which was added a pension of sixty pounds. In 1607, upon Coke's promotion to the bench, Bacon was appointed solicitor-general; and he became attorney-general in 1612. His treatises concerning improvements in the law, and the principles of legislation, are more creditable testimonies to the value of his official services than some others of his acts; such as the scheme, first tried in the session of 1614, for securing majorities in the House of Commons by organised corruption, the invention of which has been recently traced to him, although in his place in parliament he ridiculed those who asserted that such a project had ever been formed. Bacon was likewise officially the prosecutor of Oliver St. John, of Owen and Talbot, and of the old clergyman Peacham, who was examined in the Tower under torture, the founder of modern philosophy being present, and putting the questions. In Peacham's case there was even an attempt, actively promoted by Bacon, for securing a conviction by previous conference with the judges; a plot which, though at length successful, was defeated for a time by the sturdy resistance of Coke, a tyrant to his inferiors, but a staunch opponent of encroachments upon judicial independence. Bacon's last remarkable appearance as attorney-general, was in the noted trial of the earl and countess of Somerset and their accomplices, for the murder of Sir Thomas Overbury; and, whatever the foul secret may have been, which was involved in that fiendish intrigue, Bacon's letters to the king leave little reason for doubting that he at least was in possession of it. His conduct in this matter however gained him great and deserved credit.

The fall of Somerset was followed by the rise of the new favourite Villiers, who had already profited by his intimacy with the attorney-general, and by the sound advices with which the cautious statesman endeavoured to fortify his youth and inexperience. The worthless Buckingham, destined in a few years to be the instrument of retribution for Bacon's past desertion of Essex, did not for some time forget obligations, of which he was probably wise enough to desire a continuance. In 1616, Bacon having been sworn of the privy council, relinquished the bar, but retained his chamber practice. In the spring of 1617, the Lord Chancellor Ellesmere resigned the seals, which were immediately delivered to Bacon, with the title of lord-keeper. In January of the succeeding year he was made lord high chancellor of England, and in July was raised to the peerage as Baron of Verulam. His higher title of Viscount St. Albans was not conferred on him till 1621. Without neglecting his political duties, he proceeded zealously to the judicial functions of his office, in which arrears of business had accumulated through the infirmities of his aged predecessor. "This day," wrote he to Buckingham in June 1617, "I have made even with the business of the kingdom for common justice; not one cause unheard; the lawyers drawn dry of all the motions they were to make; not one petition unanswered. And this, I think, could not be said in our age before. Thus I speak, not out of ostentation, but out of gladness, when I have done my duty. I know men think I cannot continue, if I should thus oppress myself with business; but that account is made. The duties of life are more than life: and if I die now, I shall die before the world be weary of me." And the man who wrote in this solemn moral strain, the man whose writings throughout are an echo of the same lofty expression of the sense of duty, was also the man who, in less than four years after his elevation to the seat of justice, was to be hurled from it in disgrace, branded as a bribed and dishonest man. "At York House," says Mr. Montagu, "on the 22d of January 1621, he celebrated his sixtieth birthday, surrounded by his admirers and friends, among whom was Ben Jonson, who composed a poem in honour of the day.

> Hail, happy genius of this ancient pile!
> How comes it all things so about thee smile—
> The fire, the wine, the men—and in the midst
> Thou stand'st, as if some mystery thou didst?

"Had the poet been a prophet, he would have described the good genius of the mansion not exulting, but dejected, humble, and about to depart for ever."

He had now arrived at the conviction that his worship of the powers of this world had made it impossible for him to consummate the great sacrifice, which, during his lifetime, he had hoped to lay upon the altar of philosophy. Aged sixty years, and immersed in difficult and anxious business, he felt that his great Restoration of Science, his Instauratio Magna, could not be completed; and he therefore hastened to give to the world an outline of its plan, coupled with a filling up of one section of the outline. "I number my days," wrote he, "and would have it saved." The Novum Organum, the result of this determination, was published in October 1620; and the fame which it earned for its author throughout Europe, was in its rising splendour when his fall took place.

The tempest which was soon to overturn the throne was already lowering on the horizon; and its earliest mutterings were heard in the important parliament which met on the 30th of January 1621. With most of the complaints, whose investigation the king and Buckingham feared so much, we have here little to do: but two gross abuses there were, in which the lord chancellor was personally implicated. He had passed the infamous patents of monopoly, of which the worst were those held by Sir Giles Mompesson, (Massinger's Overreach,) and by Sir Francis Michell, and shared by Buckingham's brothers and dependents: and he had allowed himself to be influenced in his judicial sentences by *re-*

Bacon.

commendations of the favourite. The first of these faults admitted of palliation, the second was susceptible of none; but both were real and heavy offences. Yet neither of them was made an article of charge against Bacon. He was attacked upon a different ground. Buckingham, by the advice of his new counsellor Williams, then dean of Westminster, abandoned the monopolists to their fate, contenting himself with sending his own brothers out of the country, and with afterwards publicly denying that he had any hand in assisting their escape. But the storm was not allayed. In March, the parliamentary committee appointed to inquire into the existence of abuses in the courts of justice, reported that abuses did exist, and that the person against whom they were alleged, was the lord chancellor himself. Two cases were specified, of suitors named Aubrey and Egerton, of whom the one had given the chancellor L.100, the other L.400, and against whom he had decided, notwithstanding these presents. Two days after this report was presented, Lord St. Albans presided in the House of Lords for the last time. New accusations accumulated against him; and, alarmed in mind, and sick in body, he retired from the house, and addressed to the peers a letter, praying for a suspension of their opinion, until he should have undergone a fair trial. In no long time the charges against him amounted to twenty-three; and Williams, again called to the councils of Buckingham and his master, advised that no risks should be incurred upon his account. A prorogation of parliament ensued, during which an interview took place between the king and the chancellor; and James, instead of encouraging his accused servant in the resolution he had expressed of defending himself, recommended "that he should submit himself to the House of Peers, and that upon his princely word he would then restore him again, if they in their honours should not be sensible of his merits." On the 24th of April there was presented to the Lords, by the Prince of Wales, a supplication and submission of the lord chancellor, in which the most important passage is the following: "It resteth, therefore, that, without fig-leaves, I do ingenuously confess and acknowledge that, having understood the particulars of the charge, not formally from the house, but enough to inform my conscience and memory, I find matter sufficient and full, both to move me to desert my defence, and to move your lordships to condemn and censure me. Neither will I trouble your lordships by singling those particulars, which I think may fall off.

Quid te exempta juvat spinis de pluribus una?

Neither will I prompt your lordships to observe upon the proofs, where they come not home, or the scruples touching the credits of the witnesses: neither will I represent unto your lordships how far a defence might, in diverse things, extenuate the offence, in respect of the time or manner of the gift, or the like circumstances; but only leave these things to spring out of your own noble thoughts, and observations of the evidence and examinations themselves, and charitably to wind about the particulars of the charge here and there, as God shall put in your minds; and so submit myself wholly to your piety and grace. . . . . And, therefore, my humble suit to your lordships is, that my penitent submission may be my sentence, and the loss of the seal my punishment; and that your lordships will spare any further sentence, but recommend me to his majesty's grace and pardon for all that is past." But not even thus was the humiliation complete. The house resolved that the submission was not specific, nor unequivocal enough to be satisfactory; and that he should be required to furnish categorical answers to the several articles of charge, which, accordingly, were sent to him, being numbered under twenty-three heads. The specific answers which he returned were prefaced and followed by these declarations: "Upon advised consideration of the charge, descending into my own conscience, and calling my memory to account, so far as I am able, I do plainly and ingenuously confess that I am guilty of corruption, and do renounce all defence, and put myself upon the grace and mercy of your lordships. . . . . This declaration I have made to your lordships with a sincere mind; humbly craving that, if there should be any mistakes, your lordships would impute it to want of memory, and not to any desire of mine to obscure truth, or palliate anything. For I do again confess, that in the points charged upon me, although they should be taken as myself have declared them, there is a great deal of corruption and neglect, for which I am heartily and penitently sorrow, and submit myself to the judgment, grace, and mercy of the court.—For extenuation, I will use none, concerning the matters themselves: only it may please your lordships, out of your nobleness, to cast your eyes of compassion upon my person and estate. I was never noted for an avaricious man, and the apostle saith, that covetousness is the root of all evil. I hope also that your lordships do the rather find me in the state of grace; for that, in all these particulars, there are few or none that are not almost two years old, whereas those that have an habit of corruption do commonly wax worse and worse; so that it hath pleased God to prepare me, by precedent degrees of amendment, to my present penitency. And for my estate, it is so mean and poor, as my care is now chiefly to satisfy my debts."

This declaration being read, a deputation of the lords was appointed to wait on the unfortunate man in the chamber where he sat deserted and alone, and to demand whether it were his own hand that was subscribed to it. Among them was Shakspeare's friend Lord Southampton, who had been condemned to death along with Essex. Bacon replied to them, "It is my act, my hand, my heart. I beseech your lordships, be merciful unto a broken reed." Again the fallen judge prayed the king to intercede for him; and again the king, his haughty son, and their thankless favourite, refused to interfere. On the 3d of May 1621, the lords pronounced a sentence which, stamping him at all events with indelible disgrace, was terrible even in the punishment which it actually inflicted. Bacon, found guilty upon his own confession, was sentenced to a fine of forty thousand pounds, and to confinement in the Tower during the king's pleasure; he was pronounced incapable of public employments, and of sitting in parliament; and prohibited from coming within the verge of the court. His judges indeed knew that the harsher part of the sentence would not be executed. Accordingly, though committed immediately to the Tower, he was released after two days' imprison ment; and the fine was remitted in the course of the au tumn, although it is a fact dishonourable (in the circumstances) to his enemy and successor Bishop Williams, that the pardon was stayed at the seal, till the king in person ordered it to be passed.

From the whole tenor of this afflicting history, it is plain that Bacon's memory cannot be cleared from very heavy imputations. Indeed, the case against him may be stated, if we push it to the utmost, in an alternative form which admits of no honourable solution. Convicted of corruption, as he was, upon his own confession, we must either believe the confession, and pronounce him a corrupt judge, or we must disbelieve it, and pronounce him a liar. Most of his biographers adopt the former alternative. Mr. Montagu's elaborate defence is really founded on something which is not very far distant from the latter. And, humiliating as either supposition is, we have, for our own part, no hesitation in believing that the truth lies nearest to that theory which imputes to the unhappy chancellor insincerity and cowardice rather than wilful corruption. We cannot indeed go so far as his enthusiastic biographer, who insists that the acts charged and confessed, were in themselves, if not quite free from moral blame, yet palliated, not only by general usage,

Bacon. but by intentions strictly honest;—that he was sacrificed by the king and the king's minion, although, if he had stood a trial, he could have obtained a full acquittal. This, we must venture to think, is a position which, if maintained to its whole extent, cannot be even plausibly defended. Neither, as we must also believe, is justice done by that other view, which has been stated more recently with such force and eloquence, that the case was one of gross bribery, gross and glaring even when compared with the ordinary course of corruption in these times; a case so bad, that the court, anxious, for their own sakes, to save the culprit, dared not to utter a word in extenuation.[1]

The fact which possesses the greatest importance for the elucidation of this unfortunate story, is that which has been founded on so elaborately by Mr. Montagu, and lately illustrated further by another writer for a different purpose.[2] The custom of giving presents was then general, not to say universal, in England. It extended much farther than the *épices* of the French parliaments; for the gifts were not fixed in amount, nor, though always expected, were they recognised as lawful perquisites. The advisers of the crown received presents from those who asked for favours: the sovereign received presents from those who approached the throne on occasions of pomp and festivity. Both these improprieties were not only universal but unchallenged. Further, judges received presents; and under certain conditions,—when, for instance, the giver had not been, and was not likely to be, a suitor in the judge's court, or even when, though he had been a suitor, the cause was ended,—this dangerous abuse was scarcely less common than the other, and scarcely regarded in a more unfavourable light. That it was wrong, all men felt; but we fear there were few indeed, who, like Sir Thomas More, refused absolutely to profit by it. High as Coke himself stood for honesty, and well as he deserved praise for this (almost his only redeeming virtue), we doubt whether his judicial character could have emerged quite untainted from a scrutiny led by common informers, discarded servants, and disappointed litigants, like that to which his unfortunate rival was subjected. Pure Bacon was not; purer than he, several of his contemporaries probably were; but we believe him to have been merely one of the offenders, and very far indeed from being the worst, in an age when corruption and profligacy, senatorial, judicial, and administrative, were almost at the acme of that excess which an indignant nation speedily rose to exterminate and to avenge.

A comparison of the charges in detail, and of the evidence adduced, with Bacon's articulate answers, as to the candour of which there is no reason to doubt, would really exhibit little or nothing which, after fair allowances are made for imperfect information and other causes of obscurity, would afford a distinct contradiction to the chancellor's own solemn averment, made in a letter to the king at an early stage of the investigation. "For the briberies and gifts wherewith I am charged, when the book of hearts shall be opened, I hope I shall not be found to have the troubled fountain of a corrupt heart, in a depraved habit of taking rewards to pervert justice; howsoever I may be frail, and partake of the abuses of the times." While he lay in the Tower, he addressed to Buckingham a letter containing these expressions: "However I have acknowledged that the sentence is just, and for reformation sake fit, I have been a trusty, and honest, and Christ-loving friend to your lordship, and the justest chancellor that hath been in the five changes since my father's time." This last sentence, indeed, when carefully weighed, will be found to contain more of truth than the writer himself perhaps intended. A judge not altogether unjust he may have been, if we compare him with his contemporaries; but he was also a trusty, and trusting, and servile friend of the royal favourite, and of other men in power. Bacon. He was a lover of the pomp of the world, to an extent highly dangerous for one who had but little private fortune, insufficient official remuneration, and habits which disqualified him for exercising a strict superintendence over the expenses of his household, or the conduct of his dependents generally. His emoluments as chancellor did not amount to three thousand pounds a-year; and, immediately on his appointment, he had used vain endeavours to have the office put on a more independent footing. His servants habitually betrayed both him and the suitors; but there can be no doubt that, continually embarrassed in circumstances, he himself was only too glad to receive the customary gifts when they could be taken with any semblance of propriety. As to his confession, while we believe it to be true in every particular instance, we believe it also in its general admission of corruption; but we likewise believe that the general admission ought to have been qualified by certain references, which would have established the truth of a remark made by Bacon in his hour of deepest suffering, that "they upon whom the wall fell were not the greatest offenders in Israel." And this, as we conceive it, was the danger which the court were so eager to avert, the danger which filled the king and Buckingham with such dismay. This was their reason for insisting that Bacon should sacrifice his own character, and abandon that line of defence which might not improbably have precipitated the revolution. Upon this assumption, their conduct throughout is intelligible and consistent; and, although one is reluctant to believe it, the assumption is not contradicted by any thing in the chancellor's character. Lofty as may still have been his abstract notions of morality, his practical views were darkened and debased by his long servitude to public office in a corrupt age. The stain which, as he well knew, the sentence of the parliament would affix upon his name, may have seemed a light thing to one who was aware how the same brand might have been justly imprinted on almost every eminent name in the kingdom. And again, neither Bacon nor his master, nor those others who were the royal advisers, were able to comprehend, in this instance, any more than elsewhere, the spirit which had already gone abroad. They did not anticipate the severity of the sentence pronounced by the House of Lords; still less did they anticipate (Bacon at least did not, nor perhaps did Williams) the universal indignation which was aroused by the fact that the highest judge in the realm had been displaced for bribery. The court gained its immediate purpose, in removing to a subsequent time the fatal struggle; but there soon arrived the fulfilment of Bacon's prophecy, that the successful attack on him would be but an encouragement and strengthening to those who aimed at the throne itself.

After his release from the Tower, Bacon, although strangely anxious to continue in London, was obliged to retire to his paternal seat of Gorhambury, near St. Albans. There he immediately commenced his History of Henry the Seventh, a work displaying but too unequivocal proofs of the dejected lassitude which had crept upon his mind. Early in next year he offered himself unsuccessfully for the provostship of Eton College, and proceeded with other literary undertakings. These included the completion of the celebrated treatise, "De Augmentis," an improvement of the older work on the Advancement of Learning. This was the last philosophical treatise which he published; although the few remaining years of his life were incessantly devoted to study and composition, and gave birth to the New Atlantis, the Sylva Sylvarum, and other works of less consequence.

Bacon.

Shortly before the king's death, he remitted the whole of the sentence on Bacon, who, however, did not again sit in parliament. His health was already broken; and in December of that year, 1625, he made his will, in which, although his affairs were really in extreme confusion, he writes as if he considered himself a wealthy man. In the spring of 1626, on his way from Gray's Inn to Gorhambury, he exposed himself to a sudden chill, by performing in a cottage an experiment which had suggested itself to him, regarding the fitness of snow or ice as a substitute for salt in preserving dead flesh. Unable to travel home, he was carried to the earl of Arundel's house at Highgate, where, after seven days' illness, he died early in the morning of Easter Sunday, the 9th of April, in the sixty-sixth year of his age. In obedience to his will, he was buried in the same grave with his mother, in St. Michael's church, near St. Albans.

It is sad beyond expression to turn to those reflections which are suggested by the life of this great man, however leniently one may be disposed to regard his weaknesses. He who founded the philosophy of modern Europe, he who brought down philosophy from heaven to earth, disentangling it from airy abstractions, and anchoring it on practical truths,—he who aided science alike by his improvements on its procedure, and his enlarged views of its end and aim, indicating observation of individual truths as the only sure guide to universal conclusions, and practical utility as the only quality which makes such conclusions worth the labour they cost,—he who did all this, was destined to furnish, by his own pitiable example, a pregnant illustration of the great principles which his writings taught. A slave to the world and its vanities, he was betrayed by the evil genius whom he served. Unable to subject reason, and passion, and imagination, to the stern control of the moral sense, he expiated, by a life of discomfort and dependence, ending in an old age of sorrow and disgrace, the sin of having misapprehended the mighty rule, which alone can save the empire of the mind from becoming a scene like ancient chaos.

Bacon's philosophy has been analysed in other parts of this work, and on his literary character we have left ourselves no space to enlarge. We can only remark the powerful effect which his singular versatility of talents exercised over the dissemination of his scientific views. "The reputation which Bacon had acquired from his Essays," says a late writer, "a work early translated into various foreign languages,—his splendid talents as an orator,—and his prominent place in public life,—were circumstances strongly calculated to attract the curiosity of the learned world to his philosophical writings." And these writings in themselves partake admirably of the character belonging to their author's works of a different class. Philosophy has seldom made herself more attractive; never has she made herself equally so in communicating lessons of such sterling value. If the works of this wonderful man were worthless as repositories of scientific thought and knowledge, they would still demand reverential study. A masterly eloquence, a union of diversified qualities of style in the highest sense of the word, distinguished even the earlier among them, and entitled those which were produced in the writer's maturer years, to rank, notwithstanding the faults they share with all prose compositions of their time, as monuments nowhere excelled in the compass of English literature.[1] (W. S.)

Bacon, *John*, who may be considered as the founder of the British school of sculpture, was born Nov. 24. 1740. He was the son of Thomas Bacon, cloth-worker in Southwark, whose forefathers possessed a considerable estate in Somersetshire.

Bacon.

At the age of fourteen he was bound apprentice in Mr Crispe's manufactory of porcelain at Lambeth, where he was at first employed in painting the small ornamental pieces of china, but soon attained the distinction of being modeller to the work. The produce of his labour was devoted by him, from his earliest years, towards the support of his parents. While thus engaged, he had an opportunity of seeing the models executed by different sculptors of eminence, which were sent to be burned at an adjoining pottery. An observation of these productions appears to have immediately determined the direction of his genius; and his progress in the imitation of them was no less rapid than his propensity to the pursuit was strong. His ardour and unremitting diligence are best proved by the fact, that the highest premiums given by the Society for the Encouragement of Arts in those particular classes in which he was a competitor, were adjudged to him nine times between the years 1763 and 1776. During his apprenticeship he improved the method of working statues in artificial stone, an art which he afterwards carried to perfection.

Bacon first attempted working in marble about the year 1763, and, during the course of his early efforts in this art, was led, by the resources of his genius, to improve the method of transferring the form of the model to the marble (technically called *getting out the points*), by the invention of a more perfect instrument for this purpose, and which has since been adopted by many sculptors both in this and other countries.[2] The advantages which this instrument possesses above those formerly employed are, its greater certainty and exactness, that it takes a correct measurement in every direction, is contained in so small a compass as not to encumber the workman, and is transferable either to the model or the marble, as may be required, without the necessity of a separate instrument for each.

In the year 1769 the first gold medal given by the Royal Academy was adjudged to Bacon, and in 1770 he was associated by that body. His first work in sculpture was a bust of His Majesty George III., intended for Christ Church College. It is said, that of sixteen different competitions in which he engaged with other artists, he was unsuccessful in one case only. His knowledge of the classic style was for a time called in question; and on occasion of the doubts which were raised on this point, he is reported to have modelled his head of Jupiter Tonans, as the most satisfactory method of repelling the charge. The objection probably originated from the circumstance, that in some of his principal works the figures were represented in the costume of modern times, of which his statue of Justice Blackstone at All Souls College, Oxford, and that of Howard in St Paul's Cathedral, are remarkable examples. But his genius was not subjected to the trammels of this or of any one style exclusively. Many of his emblematical figures are designed after the purest models, and in a taste altogether classical. Among several of this character, the monument to Mrs Draper, in the cathedral of Bristol, is exquisitely simple. In his later productions, likewise, particularly those of a monumental kind, he introduced frequent examples of the ancient style; as in the well-known monument to the Earl of Chatham in Westminster Abbey, that to Lord Robert Manners, and others which might be mentioned. "Another marble, scarcely finished at the time of his death," says Dallaway, in his *Anecdotes of the Arts in England*, "will secure him a lasting fame for originality and classical taste. It is the cenotaph lately erected in Westminster Abbey to the poet Mason. A muse, holding his profile on a medallion, reclines on an antique altar, on

[1] Montagu's Life of Bacon, *Works*, vol. xvi. parts 1 and 2, 1834. *Edinburgh Review*, vol. lxv. No. 132, article I. Stewart and Playfair, in the Preliminary Dissertations to this Encyclopædia. Napier on the Scope and Influence of the Philosophical Writings of Lord Bacon; in the *Transactions of the Royal Society of Edinburgh*, vol. viii. part 2. 1818.

[2] The invention of this pointing machine has sometimes been erroneously ascribed to the French sculptor Hudon.

Bacon. which are sculptured, in relief, a lyre, the tragic masque, and laurel wreath; all of the most correct form, as seen on ancient sarcophagi of the pure ages."

On the 4th of August 1799, Bacon was suddenly attacked with inflammation, which occasioned his death in little more than two days, in the 59th year of his age. He left a widow, his second wife, and a family of six sons and three daughters.

Of his merit as a statuary, the universal and established reputation of his works has afforded decisive proof. The various productions of this artist which adorn St Paul's Cathedral, Christ Church and Pembroke Colleges, Oxford, the Abbey Church at Bath, and Bristol Cathedral, give ample testimony to his powers; above all, those great and prominent works among the monuments in Westminster Abbey.

But it was not as an artist only that Bacon was esteemed; he was no less distinguished by the firmness of his mind, and the uprightness of his private character. His principles were deeply founded, and the virtues which he strove to attain were measured by a standard more unbending than the mere dictates of feeling or of a cultivated taste. He was an avowed believer in the truths of the Christian religion; and in him this belief exhibited its corresponding effects, by producing a consistent influence upon his whole character and conduct. With great simplicity of manners, he was in all things devoid of ostentation. Of the general powers of his mind, and particularly of his acute and just perception in matters of taste connected with his art, a very favourable opinion will be formed by those who peruse the article SCULPTURE which he contributed to Dr Rees' edition of Chambers's *Dictionary*.

See *Memoir of the late John Bacon, R.A.*, by the Rev. Richard Cecil. London, 1811. (J. G—D.)

BACON, *Sir Nicholas*, lord keeper of the great seal in the reign of Queen Elizabeth, was born at Chislehurst in Kent in 1510, and educated at the university of Cambridge; after which he travelled in France, and made some stay at Paris. On his return he settled in Gray's Inn, and applied himself with such assiduity to the study of the law, that he quickly distinguished himself; and, on the dissolution of the monastery of St Edmund's Bury in Suffolk, he had a grant from King Henry VIII., in the thirty-sixth year of his reign, of several manors. In the thirty-eighth of the same king he was promoted to the office of attorney in the court of wards, which was a place both of honour and profit. In this office he was continued by King Edward VI.; and in 1552 he was elected treasurer of Gray's Inn. His great moderation and consummate prudence preserved him through the dangerous reign of Queen Mary. Very early in the reign of Elizabeth he was knighted; and on the 22d of December 1558, he succeeded Nicholas Heath, archbishop of York, as keeper of the great seal of England, with the title of Lord Keeper; and he was also made one of the queen's privy council. He had a considerable share in the settling of religion; and, as a statesman, he was remarkable for a clear head and wise counsels. But his great parts and high preferment were far from raising him in his own estimation, as appears from the modest answer he gave Queen Elizabeth when she told him his house at Redgrave was too little for him: "Not so, madam," returned he; "but your majesty has made me too great for my house." After having held the great seal more than twenty years, this able statesman and faithful counsellor was suddenly removed from the scene of his labours. He had been under the hands of his barber, and, thinking the weather warm, had ordered a window before him to be thrown open; but he fell asleep as the current of fresh air was blowing in upon him, and awakened some time after extremely distempered. He was immediately removed into his bed-chamber, and died a few days after, on the 26th of February 1579, equally lamented by the queen and her subjects. He was buried in St Paul's, where a monument was erected to his memory. This was destroyed by the great fire of London in 1666. Granger observes that he was the first lord keeper who ranked as lord chancellor; and that he had much of that penetrating genius, solidity, judgment, persuasive eloquence, and comprehensive knowledge of law and equity, which afterwards shone forth with so great splendour in his illustrious son.

Bacon ‖ Baconthorp.

BACON, *Roger*, a Franciscan friar of great genius and learning, was born near Ilchester in Somersetshire in the year 1214. He began his studies at Oxford, but in what school or college is uncertain. Thence he removed to the university of Paris, which in those times was esteemed the centre of literature. Here, we are told, he made such rapid progress in the sciences, that he was esteemed the glory of that university, and was much honoured by several of his countrymen, particularly by his friend and patron, Robert Greathead, afterwards bishop of Lincoln. About the year 1240 he returned to Oxford, and, assuming the Franciscan habit, prosecuted his favourite study of experimental philosophy with unremitting ardour and assiduity. In this pursuit, in experiments, instruments, and scarce books, he tells us he spent, in the space of twenty years, no less than 2000 livres, which, it seems, was given him by some of the heads of the university to enable him to continue his interesting inquiries. But such extraordinary talents, and astonishing progress in sciences which, in that ignorant age, were totally unknown to the rest of mankind, whilst they raised the admiration of the more intelligent few, failed not to excite the envy and malice of his illiterate fraternity, who found no difficulty in possessing the vulgar with the notion that Bacon dealt in the magic art. Under this pretence he was restrained from reading his lectures; his writings were confined to his convent; and, finally, in 1278, he was himself imprisoned in his cell. At this time he was sixty-four years of age. Nevertheless, being permitted the use of his books, he persevered in the rational pursuit of knowledge, corrected his former labours, and wrote several curious essays. When he had been ten years in confinement, Jerome de Ascoli being elected pope, Bacon solicited his holiness for release, but did not immediately succeed in his object. However, towards the latter end of that pope's reign he obtained his liberty, and spent the remainder of his life in the college of his order, where he died, according to Anthony à Wood, in 1292, and was buried in the Franciscan church. Bale and others have enumerated a large list of works as written by Bacon, and existing in manuscript in various collections. Several of his tracts were published in the work entitled *Epistolæ Fratris Rogeri Baconis de Secretis Operibus Artis et Naturæ, et de Nullitate Magiæ*. Paris, 1542, 4to; Basil, 1593, 8vo. His *Opus Majus*, which forms a sort of digest of his preceding writings, was first published in 1733, in a handsome folio volume by Dr Jebb. Some of his chemical tracts may be found in the *Thesaurus Chemicus*, published at Frankfort in 1603 and 1620. By an attentive perusal of his works the reader will find that Roger Bacon was a great linguist and a skilful grammarian; that he was well versed in the theory and practice of perspective; that he understood the use of convex and concave glasses, the camera obscura, burning-glasses, &c.; that he was conversant in geography and astronomy; that he knew the great error in the calendar, assigned the cause, and proposed the remedy; that he understood chronology well; that he was in all probability the inventor of gunpowder; that he possessed considerable knowledge in the medical art; and that he was an able mathematician, logician, and theologist.

BACONTHORP, JOHN, called *the Resolute Doctor*, a learned monk, born towards the end of the 13th century, at Baconthorp, a village in Norfolk. After spending the early

Bactria || Badajos.

part of his life in the convent of Blakeney, near Walsingham, he removed to Oxford, and from thence to Paris, where he obtained great reputation for his learning, and was esteemed the principal of the Averroists. In 1329 he returned to England, and was chosen twelfth provincial of the English Carmelites. In 1333 he was sent for to Rome, where, we are told, he first maintained the pope's sovereign authority in cases of divorce; but this opinion he is understood to have afterwards retracted. He died in London in 1346. He wrote, 1. *Commentaria, seu Quæstiones super quatuor libros Sententiarum;* and, 2. *Compendium Legis Christi, et quodlibeta;* both of which passed through several editions.

BACTRIA, or BACTRIANA (now Bokhara), an ancient kingdom of Asia, bounded on the W. by Margiana, N. by the river Oxus, E. by Asiatic Scythia, and S. by the Paropamisan, range. This country was very fertile, and inhabited by a numerous and warlike race. It became a Persian province about the time of Cyrus, and afterwards figured in the wars of Alexander, being celebrated for its cavalry. It formed part of the kingdom of the Seleucidæ; but about B.C. 256, Theodotus, who was the governor, threw off the Grecian yoke, and Bactria remained independent till about B.C. 126, when it was conquered by the Parthians. Its capital was Bactra or Zariaspa, corresponding to the modern town of Balk. The history of Bactria began to be illustrated by Colonel Tod's discovery of Bactrian coins (*Royal Asiatic Soc. Trans.* 1824); since which time various travellers have completed the series, such as now found in the Parisian and London Museums. See BOKHARA, BALK.

BACTRIS, an American genus of low palms, found in equinoctial regions, in the neighbourhood of rivers, or in marshy grounds. Martins describes 17 species. The leaves spring from all parts of the stem.

BACULARIUS, in writers of the middle age, an ecclesiastical apparitor or verger, who carries a staff, *baculus*, in his hand, as an ensign of his office.

BACULE (French, *Bascule*), in *Fortification*, a kind of portcullis or gate, made like a pit-fall with a counterpoise, and supported by two large stakes. It is usually erected before the corpade guard, not far from the gate of a place.

BADAJOS, a province of Spain, forming, by the division of 1833, the southern half of the old province of Estremadura, or what is generally called Lower Estremadura. It is bounded on the N. by Caceres, E. by Ciudad Real, S. and S.E. by Cordova, Sevilla, and Huelva, and W. by Portugal, embracing an area of 596 square leagues. It contains 15 *partidos*, 162 *ayuntamientos*, 4 cities, 123 towns, and 45 villages; pop. in 1849, 336,136. See ESTREMADURA.

BADAJOS, a fortified city of Spain, the capital of the above province, and the see of a bishop. It is situated about 5 miles from the Portuguese frontier, on a slight elevation near the left bank of the Guadiana. The height is crowned by the ruins of a Moorish castle. A strong wall and bastions, with a broad moat and outworks, and forts on the surrounding heights, make the city a place of great strength. The river is crossed by a magnificent granite bridge, originally built in 1460, repaired in 1597, and rebuilt in 1833. The city is well built, and contains an arsenal, a cathedral, 6 churches, and several hospitals and schools. Its 5 monasteries are all secularized; one is occupied as infantry barracks; and of its 8 nunneries 4 are closed. Badajos from its importance as a frontier garrison has been the scene of numerous sieges. The last and most severe was in 1812, when it was stormed by the British troops under Wellington, and carried with dreadful loss. It had been surrendered in the previous year to Soult by the treachery of Imaz the commander of the garrison. The legitimate trade and manufactures of Badajos are inconsiderable; but much contraband traffic is carried on with Portugal. Pop. 11,480.

Badajos is the *Pax Augusta* of the Romans, corrupted by the Moors into *Paxagousa*, *Baxagus*, *Badaxos*.

Badakshan || Baden.

BADAKSHAN, or BUDUSCHAN, a mountainous district, situated to the N. of the great Himalaya ridge, which bounds Hindustan on the N. It is about twenty days' journey E.S.E. of Bokhara, and nearly S. of Kokaun. It comprehends the higher valley of the Amoo, which is here called the Jihon or the Jaxartes, together with all the other valleys of its tributary streams, and all the mountains connected with them as far nearly as the sources of that river. The district of Badakshan rises gradually to its level from the lower and northern part of the province of Balk, which occupies the left bank further down the river. This country is described as mountainous and well wooded, and the people as uncivilized, and even savage in their manners. They live in villages surrounded with gardens, and situated in the little glens and recesses of the hills. The mountainous districts of this province are famed for some of the richest mines of lapis lazuli and of rubies that are known. The former is found in veins, sometimes of considerable thickness, in a gray matrix; and masses of this stone are occasionally procured capable of being wrought into large slabs. They are carried to Bokhara for sale, and thence to Russia. The rubies are found imbedded in a white earth, in large masses of crystal. Some large and coarse crystals are also found, as well as emeralds, according to the information of Fraser. The chief town is Fyzabad, which is said to be not more than 150 miles from Balk. There is another town of the same name as the province, and of considerable importance. Mr Fraser could gain little authentic information concerning the people of this remote country, their habits, or the nature of their government. They are, however, rigid and intolerant Mahometans, among whom it would be dangerous for any European to reside. (Fraser's *Journey into Khorassan.* Elphinstone's *Cabul.*)

BADALOCCIO, SISTO, a painter and engraver, born at Parma about the end of the 16th century. He was of the school of A. Caracci, by whom he was highly esteemed for design. His principal engravings are the series known as *The Bible* of Raffaello.—(Lanzi, *Storia Pittor.*)

BADALONA (*Bætulo* of the Romans), a town of Spain, in the province of Barcelona, pleasantly situated on the seacoast, 10 miles N.E. of Barcelona. It is remarkable as the landing place of the Archduke Charles of Austria and the Earl of Peterborough, in the war of the succession in 1704. Pop. 5000, mostly seamen and fishermen.

Boundaries

BADEN, GRAND DUCHY OF, is situated in the S.W. of Germany, between Lat. 47. 32. and 49. 52. N.; and Long. 7. 27. and 9. 50. E. It is bounded on the N. by Bavaria and Hesse-Darmstadt; W. by Rhenish Bavaria and France; S. by Switzerland; and E. by Wirtemberg and the principality of Hohenzollern. At the commencement of the present century, Baden was only a margraviate with an area little exceeding 1300 square miles, and a population of 210,000. Since then it has from time to time acquired additional territory, so that its area now amounts to upwards of 5900 square miles, and its population to nearly a million and a half.

History.

The margraves of Baden belonged to the Zähringen family, the founder of which was Berthold, landgrave of Breisgau, who flourished about the middle of the 11th century. Berthold's third son, Hermann, acquired Baden by marriage; and his grandson, Hermann II., fixed his residence at Baden, and took the title of margrave. Margrave Christopher I. was succeeded on his death in 1527 by his three sons, one of whom however died soon after, and the margraviate was divided among the two survivors, who thus formed the two lines of Baden-Baden and Baden-Durlach. The line of Baden-Baden became extinct by the death of Augustus George in 1771, and its possessions were united with Baden-Durlach under Charles Frederick. By the treaty of Luneville con-

Baden. cluded in 1801, Baden acquired a considerable addition of territory, which was farther increased in 1803 when the margrave received the title of elector. The treaty of Presburg, in 1805, still farther increased his domains, by the addition of Breisgau, so that Baden had then an area of 3455 square miles, with 670,000 inhabitants. On the dissolution of the German empire, and his joining the confederation of the Rhine, in 1806, the elector received the title of Grand Duke, and 1950 square miles of additional territory. Some smaller additions at subsequent periods have increased Baden to its present extent.

Population In 1832 it was divided into 4 circles, 74 bailiwicks, and 1595 communes. By the census of 1849, the population was 1,362,774; of whom 905,143 were Roman Catholics, 432,184 Protestants, and 23,547 Jews. The following table gives the extent and population of each of the four circles according to the census of 1852:—

Circles.	Square Miles.	Bailiwicks.	Communes.	Pop. in 1852.
Lake,	1303	15	376	199,075
Upper Rhine,	1654	18	448	349,205
Middle Rhine,	1633	21	389	462,085
Lower Rhine,	1314	20	382	346,578
	5904	74	1595	1,356,943

Baden contains 115 cities, 45 market towns, 1634 villages, and 533 hamlets. The capital of the duchy is Carlsruhe: Pop. 23,217.

Physical features. Baden is principally of a mountainous or hilly character, interspersed with fertile and pleasant valleys. On the western side of this country, and extending along the Rhine, is a very fertile stripe of land, from which the rest of the country rises towards the east. In the southern and eastern parts is the Black Forest (Schwarzwald), extending northwards as far as the Neckar, north of which is the Odenwald range, sometimes considered as a part of the Schwarzwald, but considerably less elevated. The highest peaks of the Black Forest are the Feldberg and the Belchen, which attain respectively the height of 4650 and 4397 feet: the Katzenbückel, the highest point of the Odenwald, is only 2180 feet high. Lying between the Rhine and the Treisam is the *Kaiserstuhl*, an independent volcanic group, nearly 10 miles in length and five in breadth, the highest point of which is 1760 feet.

This country is watered by numerous rivers and streams: of these, the principal is the Rhine, which is the recipient of almost all the rest, and forms the boundary of the duchy on the S. and W. Among its other rivers are the Mayn, Tauber, Neckar, Murg, Kinzig, Wutach, Pfinz, and Elz. The Danube too takes its rise here. Baden has also a number of lakes, as the Mummel Wilder, Nonnenmattweiher, Titti, Eichener, Schluch, &c. A part of Lake Constance belongs to Baden.

Climate. The climate of Baden varies considerably with the elevation, but is everywhere very salubrious. In the plains and valleys it is mild and agreeable, but in the higher parts it is cold and moist, with snow during a great part of the year; and the transition from winter to summer is often very sudden.

Agriculture. The inhabitants are chiefly engaged in agricultural and pastoral pursuits, for which their country affords many advantages. In the valleys and plains the soil is particularly fertile and productive, yielding most luxuriant crops of wheat, maize, barley, beans, potatoes, flax, hemp, and tobacco; and even in the mountainous parts, rye, wheat, and oats are extensively cultivated. There is also a considerable extent of pasture land, and a great part is covered with woods. The vineyards are extensive, producing various kinds of excellent wine, and the gardens and orchards supply abundance of fruits of the finest description, especially almonds, chestnuts, and walnuts. The distribution of the surface of the duchy is as follows:—

Baden.

	Morgens.	Per cent.
Arable	1,476,626	or 34·8
Meadow	406,613	9·6
Pasture	225,759	5·3
Vineyards	68,064	1·6
Gardens	37,507	0·9
Woods and Forests	1,296,861	30·5
Quarries, Gravel and Clay Pits	102	0·0
Waste land	21,214	0·5
Buildings, Roads, and Waters	711,594	16·8
	4,244,340	100·0

Manufactures. The manufactures of Baden were formerly very insignificant, but latterly they have been much improved. They are, however, chiefly confined to iron and hardware goods, and the spinning and weaving of cotton. The inhabitants of the Black Forest have long been celebrated for their dexterity in the manufacture of wooden ornaments and toys, watches, clocks, musical boxes, organs, &c. There are extensive government salt-works at Durrheim and Rappenau, and iron-works at Albbrugg and other places. The mines of Oberwert and Kandern produce excellent iron. Silver, gold, and copper are also among its mineral productions, as well as alum, vitriol, sulphur, and coal. Gold washing, formerly extensively carried on along the Rhine, is now little practised. The mineral springs of Baden are very numerous, and have acquired great celebrity.

Minerals.

Commerce. The exports of Baden are very considerable, and exceed a million sterling per annum, consisting chiefly of its agricultural and industrial products. It has about 75 leagues of railways, the principal of which is that traversing almost the entire length of the country, from Mannheim to Basle in Switzerland, and of which 62 leagues are in Baden.

Education. The educational institutions of Baden are numerous and flourishing. There are two universities, the Protestant one at Heidelberg, founded in 1386, and the Catholic one at Freiburg, founded in 1457. The attendance at the former in 1849 was 543, at the latter 368. There are also 6 lyceums, 5 gymnasiums, 4 normal schools, 19 higher and 7 Latin schools, besides about 2000 common schools established throughout the country. There is an institution in Pforzheim for the deaf and dumb, and one in Freiburg for the blind. A polytechnic school was established about 18 years ago at Carlsruhe, and is now perhaps the most efficient institution of the kind in Germany. It has a staff of 41 teachers, and about 330 students. The preparatory course extends over three years, and includes French, German, English, general history, mathematics, drawing, modelling, chemistry, mineralogy and geology, mechanics, &c. The special courses are engineering, architecture, forestry, chemistry, mechanics, commerce, and post-office service; and extend over from one to four years.

Government. The government is a hereditary monarchy, vested in the grand duke, who enjoys the executive and judicial powers, but is assisted in the legislative by two chambers, the one of peers, and the other of deputies. The chamber of peers consists of 36 members, 8 of whom are chosen by the grand duke, and one by each of the two universities; the remaining members are, the Roman Catholic archbishop of Freiburg, a Protestant prelate, and the principal nobility. The chamber of deputies has 64 members, elected by all the males who have attained their twenty-fifth year. Each member must be at least 30 years of age, and is elected for 8 years; one-fourth of the members going out every two years.

Baden occupies the seventh rank in the Germanic confederation, and furnishes a contingent of 10,000 men to the federal army. It has three votes in the full diet, and one in the minor assembly. By the approved budget of 1852 and 1853, the clear united revenue for these years was fixed at 19,536,497 florins (L.1,628,041), and the expenditure at 19,545,723 florins (L.1,628,810). The public debt in 1852 was 60,894,107 florins (L.5,074,509), of which

Revenue.

Baden || Badia y Leblich.

32,609,791 florins (L.2,717,482) was a loan contracted for the construction of railways in the country.

BADEN, or BADEN-BADEN, a town and celebrated watering-place of Germany, in the circle of Middle Rhine and Grand Duchy of Baden. It stands on the Oos, in a valley of the Black Forest, 18 miles S.W. of Carlsruhe; and it is connected by a branch with the Mannheim and Basle railway. Baden during the months of July and August is frequented by great numbers of visitors from all parts of Europe, so that its resident population, which is only about 6000, is frequently augmented to three times that number. There are thirteen hot springs, varying in temperature from 37° to 54° R., = 115° to 156° F.; and the water is conveyed through the town in pipes to supply the different baths. The superiority of its situation, its extensive pleasure-grounds, gardens, and promenades, render Baden one of the first watering-places in Germany. It was for six centuries the residence of the margraves of Baden. The "old castle" occupying the summit of a hill above the town, was the earliest residence of the reigning house; and the "new castle" (so called by comparison), situated close to the town, is remarkable for its subterranean dungeons. Baden has a library and reading-room, theatre, assembly rooms, and the other accessaries of a fashionable watering-place. The parish church contains monuments of several of the margraves. The springs of Baden were known to the Romans under the name of *Aurelia Aquensis*, and fragments of ancient sculpture are still to be seen there. In 1847 remains of Roman vapour baths, well preserved, were discovered just beneath the new castle.

BADEN, a small town of Switzerland, in the canton of Aargau, on the Limmat, 14 miles N.W. of Zurich. It is much resorted to, principally by the Swiss, on account of its hot medicinal springs. The treaty of 1714 between France and Germany was concluded here. Pop. 2500.

BADEN, a small city in the Austrian province of the Lower Ens, in the circle of Wiener Wald. It is about twelve miles from Vienna, and is the most fashionable summer resort of the inhabitants of that capital. The situation is highly romantic, and the prospects in its vicinity are picturesque and beautiful. It has many warm baths, which are much resorted to by invalids. Accommodations and amusements are here as amply furnished to the visitors as at the other German spas. Baden suffered much by a fire in 1812, but has since been very elegantly rebuilt. The Archduke Charles has a residence at this place, which is a favourite retirement of the imperial family. The stationary population amounts to 4000. Baden stands on the rapid river Schwachat, whose water-falls greatly enhance its natural beauties.

BADENOCH, a district of Inverness-shire in Scotland. (See INVERNESS-SHIRE.)

BADENS, FRANCIS, an historical and portrait painter, born at Antwerp in 1571; died in 1603. He was distinguished by the warmth of his colouring, for which he has been surnamed *the Italian*.

BADEN-WEILER, a village in the Grand Duchy of Baden, and circle of Upper Rhine, celebrated for its alkaline thermal springs and baths. Remains of Roman baths still exist here.

BADGER. See MAMMALIA, *Index*.

BADIA Y LEBLICH, DOMINGO, a celebrated Spanish traveller, better known under his assumed name of Ali Bey, was born in Biscay in the year 1776. After receiving a very liberal education, he made himself master of the Arabic language, and the usages of the Mussulmans, with a view to facilitate his Oriental travels. He was employed by the French government as a political agent in the East; and after submitting to the rite of circumcision, he assumed the Mussulman costume, in which disguise he visited Egypt, Arabia, and Syria, and was received as a person of high rank wherever he appeared He returned to Europe; but again visiting the East, he died at Aleppo in 1819, it is said by poison. His travels appeared in 1814, under the title of *Voyage d'Ali Bey en Asie et en Afrique*, &c., in 3 vols. 8vo, and they have been translated into English.

Badile || Baeza.

BADILE, ANTONIO, an historical and portrait painter, born at Verona in 1480. He was confessedly an eminent artist; but he derived greater honour from having had two such disciples as Paolo Veronese and Baptista Zelotti, than from the excellence of his own compositions. He died in 1560.

BADIUS, JODOCUS or JOSSE, sometimes called BADIUS ASCENSIUS, from the village of Asche near Brussels, where he was born in 1462, was an eminent printer at Paris, whose establishment was celebrated under the name of *Prelum Ascensianum*. He illustrated with notes several of the classics which he printed, and was himself the author of numerous pieces, amongst which are a life of Thomas à Kempis, and a satire on the follies of women, entitled *Navicula Stultarum Mulierum*. He died in 1535.

BAENA, a town and *partido* in the province of Cordova in Spain. The town, 8 leagues S.E. of Cordova, is picturesquely situated on the slope of a hill crowned with a castle, near the river Marbello. It has four parish churches and three schools, one of which, a female college, with an attendance of 167 pupils (1847), has a high reputation in the province. The education, which is conducted by Sisters of Charity, does not go beyond reading, writing, arithmetic, and religious instruction. Grain and oil are the principal articles of commerce. Pop. 12,944. The site of the Roman town (*Baniana* or *Biniana*) can still be traced, and various antiquities are to be met with. A subterranean vault was discovered in 1833, containing twelve cinerary urns with inscriptions commemorating various members of the Pompeian family.

BÆTICA, a province of ancient Spain, so called from the famed river Bætis, now Guadalquivir. It was bounded on the W. and N.W. by Lusitania, on the S. by the Mediterranean and Sinus Gaditanus, and on the E. and N.E. by Tarraconensis.

BÆTYLIA (*βαίτυλια*, *βαίτυλοι*), anointed stones, worshipped by the Phœnicians and other barbarous nations. They were commonly of a black colour, and consecrated to some god, as Saturn, Jupiter, the sun. Some are of opinion that the true original of these idols is to be derived from the pillar of stone which Jacob erected at Bethel, and which was afterwards worshipped by the Jews. These *bætylia* were the objects of much veneration among the ancient heathens. Many of their idols were in fact no other; and no sort was more common in Eastern countries than that of erect oblong stones, hence termed by the Greeks *κιόνες*, *pillars*. Dædalus separated the mass into two feet, whence he is said to have made *walking statues*. In some parts of Egypt they were planted on both sides of the highways. In the temple of Elagabalus in Syria, there was one said to have fallen from heaven; and in Phrygia there was a black stone, also considered an aerolite; which the Romans sent for, and received with much ceremony, Scipio Nasica being at the head of the embassy.

BAEZA (ancient *Beatia*), a city and *partido* in the province of Jaen in Spain. The city, which is well built, stands on a considerable elevation, about 3 miles from the right bank of the Guadalquivir. Lat. 37. 59. N. Long. 3. 28. W. It has a cathedral and several fine public buildings, among which the most worthy of notice are the university, the oratorio of St Philip Neri, the marble fountain with Caryatides in the Plaza de la Constitucion, the gates "de Cordoba y Ubeda," and the arch of Baeza. The latter are among the remains of its old fortifications, which were of great strength. There is little trade or manufacture here. The principal productions of the neighbourhood are grain and oil. The red dye made from the native cochineal was

Baffa ‖ Baghdad.

once celebrated; but this, as well as other branches of industry, has fallen greatly in importance. In the time of the Moors, Baeza was a flourishing city of 50,000 inhabitants. Present pop. about 11,000.

BAFFA, a town in the island of Cyprus, with a fort built near the site of the ancient Paphos, of which some ruins yet remain, particularly fragments of columns, which probably belonged to a temple of Venus. Long. 32. 20. E. Lat. 34. 50. N. See PAPHOS.

BAFFIN, WILLIAM, an able and enterprising English seaman, born in 1584. His descriptions of part of the bay which bears his name have been found remarkably accurate by later navigators. His voyages to those regions were performed in 1612, 1613, 1615, and 1616, while he was only a subordinate; but he gave the accounts of the discoveries. In 1618 he was mate in a voyage to Surat and Mocha; but in 1621 he was killed, while attempting, in conjunction with a Persian force, to expel the Portuguese from Ormuz. —(Purchas's *Pilgrimage.*)

BAFFIN'S BAY, a large inland sea separating Greenland from the N.E. coast of America, and extending from 68° to 78° N. Lat., and from 52° to 80° W. Long. It was first explored in 1616 by the English navigator Baffin. It is connected by Davis's Strait with the Atlantic, and by Lancaster Sound and Barrow's Strait with the Arctic Ocean. The coasts are generally high and precipitous, and are deeply indented with gulfs. During the greater part of the year this sea is frozen, and is only navigable from the beginning of June to the end of September. It is annually visited by vessels engaged in the whale and seal fishery.

BAFRA, a town of Asia Minor, pashalic of Sivas, on the right bank of the Kizil Ermak, 13 miles from its mouth in the Black Sea. It has a fine bridge and two mosques, and some trade in rice and tobacco. Pop. about 3000.

BAGHDAD, a city of Asia, formerly the capital of the empire of the khalif, and long renowned for its commerce and its wealth. It is situated on an extensive and desert plain, with scarcely a tree or village throughout its whole extent; and, though it is intersected by the Tigris, it stands mostly on its eastern bank, close to the water's edge. Old Baghdad on the W. is now considered only as a suburb to the larger and more modern city on the eastern shore. It has, however, numerous and extensive streets, well furnished with shops, and is protected by strong walls, with three gates opening towards Hillah on the Euphrates and Kazameen. Beyond these recent bulwarks, vestiges of ancient buildings, spreading in various directions, are visible in the plain, which is strewed with fragments of brick, tiles, and rubbish. A burying-ground has extended itself over a large tract of land formerly occupied by the streets of the city; and here is the tomb of Zobeida, the favourite wife of Haroun el Raschid, built of brick, of a high octagonal shape, and surmounted by a lofty superstructure in the form of a cone. The two towns of Old and New Baghdad are connected by a bridge of thirty pontoons. The form of the new city is that of an irregular oblong, about 1500 paces in length by 800 in breadth; and a brick wall, 1500 paces in length and about five miles in circuit, incloses the town on both sides of the river. This wall, which is built of brick, has been constructed and repaired at different periods; and, as in most other works of the same nature in Mahometan countries, the oldest portion is the best, and the more modern the worst part of the fabric. At the principal angles are large round towers, with smaller towers intervening at short distances; and on these large towers batteries are planted, with about fifty brass cannon of different calibre, badly mounted. In two of these angular towers, Mr Buckingham remarked that the workmanship is equal to any ancient masonry that he had ever seen. The wall has three gates, one on the S.E., one on the N.E., and a third on the N.W. of the city; and it is surrounded by a dry ditch of considerable depth. The town has been built without the slightest regard to regularity. The streets are even more intricate and winding than those in most other Eastern towns; and, with the exception of the bazaars and some open squares, the interior is little else than a labyrinth of alleys and passages. The streets are unpaved, and in many places so narrow that two horsemen can scarcely pass each other; and as it is seldom that the houses have windows facing the great public thoroughfares, and the doors are small and mean, they present on both sides the gloomy appearance of dead walls. All the buildings, both public and private, are constructed of furnace-burnt bricks, of a yellowish-red colour, taken chiefly from the ruins of other edifices, as their rounded angles evidently show. A house is generally laid out in ranges of apartments opening into a square interior court, and furnished with subterranean rooms called *serdaubs*, into which the inhabitants retreat during the day for shelter from the intense heats of summer; and with terraced roofs, on which they take their evening meal, and sleep in the open air. In the months of June, July, and August, the thermometer at break of day generally stands at 112° of Fahrenheit; at noon it rises to 119°, and a little before two o'clock to 122°; at sunset it is about 117°; and at midnight 114°. In some seasons it rises even higher; and at these times the inhabitants during the day take refuge in the subterranean apartments, where they endeavour, by every possible device, to mitigate the intolerable heat. The interiors of the houses of the rich are splendidly furnished, and ornamented in the ceilings with a sort of chequered work, which has a handsome appearance. A great portion of the ground within the walls of the town is unoccupied by buildings, especially in the north-eastern quarter; and even in the more populous parts of the city, near the river, a considerable space between the houses is occupied by gardens, which produce pomegranates, grapes, figs, olives, and dates, in great abundance; so that the city when seen from a distance, has the appearance of rising out of the midst of trees.

Baghdad.

The public buildings in Baghdad are chiefly the mosques, the khans or caravanserais, and the serai or palace of the pasha. This latter building, which is situated in the north-western quarter of the town, not far from the Tigris, is distinguished rather for extent than grandeur. It is a comparatively modern structure, built at different periods, and forming a large and confused pile, without proportion, beauty, or strength. There are no remains of the ancient palace of the khalifs.

In all Mahometan cities the mosques are conspicuous objects. The number in Baghdad is above 100; but of these not more than thirty are distinguished by their particular minarets or steeples, the rest being merely chapels and venerated places of prayer. The most ancient of these mosques was erected in the year of the Hegira 633, or 1235 of the Christian era, by the Khalif Mostanser. All that remains of the original building is the minaret, and a small portion of the outer walls; the former a short, heavy erection, of the most ungraceful proportions, built of bricks of various colours, diagonally crossed. The jamah or mosque of Merjameeah, not far distant from the former, though the body of it is modern, has some remains of old and very rich arabesque work on its surface. The door is formed by a lofty arch of the pointed form, bordered on both sides by rich bands exquisitely sculptured, and having numerous inscriptions. The mosque of Khassakey is chiefly distinguished by the niche for prayer, which, instead of a simple and unadorned recess, is crowned by a Roman arch, with square pedestals, spirally fluted shafts, a rich capital of flowers, and a fine fan or shell-top in the Roman style. Around the arch is a sculptured frieze; and down the centre, at the back of the niche, is a broad band, richly sculptured with

Baghdad. vases, flowers, &c., in the very best style of workmanship; the whole executed on a white marble ground. The mosque of the vizier, near the Tigris, has a fine dome and lofty minaret; and the great mosque in the square of El Maidan is also a noble building. The others do not merit any particular notice. The domes of Baghdad are mostly high, and disproportionately narrow. They are richly ornamented with glazed tiles and painting, the colours chiefly green and white, which, being reflected from a polished surface, impart more of liveliness than magnificence to the aspect of these buildings. But, in the opinion of Mr Buckingham, they are not to be compared to the rich and stately domes of Egypt, as the minarets, although they have the same bright assemblage of colours, are far from being equal "to the plain and grave dignity of some of the Turkish towers at Diarbekir, Aleppo, and Damascus, or to the lighter elegance of many of those in the larger towns on the banks of the Nile."[1]

There are about thirty khans or caravanserais in Baghdad, all of inferior construction to those in the other large towns of Turkey. The bazaars, which are numerous, are mostly formed of long, straight, and tolerably wide avenues. The one most recently built is the largest and the best; still it has an air of meanness about it that is not common in the bazaars of large Turkish cities. It is long, wide, and lofty, and well filled with dealers and wares of all sorts. Several of these bazaars are vaulted over with brick-work; but the greater number are merely covered with flat beams which support a roof of straw, dried leaves, or branches of trees and grass. There are about fifty baths in Baghdad, which are also very inferior in their accommodations to those in the other large towns of Mesopotamia.

Baghdad is about 500 miles from the mouth of the Tigris, following its course, and about 400 from Bassora; and with this latter place it carries on a constant communication by means of boats, of from twenty to fifty tons burden, though the river is navigable for larger vessels. With a northerly wind these boats will make the passage to Bassora in seven or eight days; in calms, when they have merely the aid of the current, the passage occupies from ten to fifteen days. Sir R. K. Porter mentions that the stream of the Tigris runs at the rate of seven knots an hour. This, however, is probably during floods, since, with such a powerful current, a boat could not occupy ten or fifteen days on its passage from Baghdad to Bassora. In coming up the stream, thirty or forty days are consumed before reaching Baghdad. The smaller craft, used for bringing supplies of provisions and fruit to the city, are circular boats of basket-work, covered with skins, the same that have been employed from the remotest antiquity. The communication with Bassora used formerly to be carried on by the way of Hillah on the Euphrates; but the banks of this river are now in possession of a tribe of Arabs, who detain and plunder all vessels sailing down the river, and frequently murder the crews. The Euphrates and the Tigris are liable to spring floods; and the streams of both rivers being joined, inundate the desert plain on which Baghdad stands, when the city appears like an island in the midst of the sea. The inhabitants are supplied with water from the Tigris, which is brought to their houses in goats' skins; the convenience of water-works, cisterns, and pipes, being entirely unknown.

Baghdad has declined from its ancient importance. It was formerly a great emporium of Eastern commerce; and it still receives, by way of Bassora, from Bengal, the manufactures and produce of India, which are distributed over Arabia, Syria, Kurdistan, Armenia, and Asia Minor. At the same time the inland trade from Persia and the East has declined. The productions and manufactures of Persia which were intended for the Syrian, Armenian, and Turkish markets, and were sent to Baghdad as a central depôt, now reach Constantinople by the more direct route of Erzerum and Tocat. Wealth appears to be deficient among all classes, and Baghdad has many symptoms of a decayed city. Baghdad.

The population is a mixture of nations from various quarters of the East. The chief officers of government, whether civil or military, are of the families of Constantinopolitan Turks, though they are mostly natives of the city; the merchants and traders are almost all of Arabian descent; while the lower classes consist of Turks, Arabs, Persians, and Indians. There are some Jews and Christians, who still remain distinct from the other classes; while the strangers in the town are Kurds, Persians, and Desert Arabs in considerable numbers. The dress of the Baghdad Turks is not nearly so gay or splendid as that of their northern countrymen; and the costume of the Baghdad residents is, upon the whole, unusually plain in comparison with that of other Asiatics. As every nation retains its own peculiar dress, it may be easily conceived what an amusing variety of costume must be seen in the streets of Baghdad. The dress of the females is as mean as that used in the poorest villages of Mesopotamia; women of all classes being enveloped in a blue checked cloth, such as is worn by the lowest orders in Egypt, and having their faces covered by hideous veils of black horse-hair.

Baghdad is governed by a pasha, assisted by a council. The pasha receives his appointment from the sultan of Constantinople; which, however, has to be ratified by the public voice, not ascertained by votes, but expressed in the tumultuous acclamations of the populace. The pasha is chosen from a body of Georgian Mamelukes, maintained by importations from Georgia, which are said to increase every year. Among this body are distributed all the lucrative offices, as well as all the military commands. The pasha has a force of 2000 horsemen, 10 pieces of artillery, and a body-guard consisting of 1000 men. On particular emergencies he can call for the service of some Arab tribes of the Desert, who are bound to this duty in return for provisions supplied by the pasha. The pashas of Kurdistan also aid him with 5000 or 6000 horse in case of need; so that on a short notice he can collect a force of 20,000 or 30,000 undisciplined troops for the defence of the city. He is generally considered as quite independent of the sultan of Constantinople. His revenue arises from a custom-duty on all merchandise entering Baghdad; and he seldom resorts to forced exactions for the supply of his treasury. The moderation and justice pursued by the government has the effect of giving great activity to commerce, and general satisfaction to all engaged in it. The police, however, is extremely defective, and murders frequently take place at the gates of the palace and of the great mosque, without any attempt being made to bring the criminals to justice. Mr Buckingham mentions that one murder was committed in open day, in the street, before a hundred witnesses, not one of whom thought of interfering; it being, according to the maxims of the Arabs, an affair of blood, which it belonged to the relatives of the slain to revenge, or the pasha to investigate, and which they had no business to meddle with. Robberies are also frequently committed with impunity. The English and French maintain each a consul at Baghdad. The late Mr Rich, whose amiable qualities furnished a theme of praise to every traveller, was appointed to that situation by the East India Company, with a large establishment, and was considered the most powerful man in Baghdad next to the pasha.

Baghdad was founded by Al Mansour, second khalif of the race of Abbas, in the 145th year of the Hegira (A.D. 767). It was adorned with many noble and stately edifices by the magnificence of the renowned Haroun el Raschid, who also built on the eastern side of the river, connecting

[1] Buckingham's *Travels in Mesopotamia*, vol. ii. chap. vii.

Baghdad.

the two quarters of the town by a bridge of boats. Under the auspices of Zobeida, the wife of that prince, and Jaffer Barmecide, his favourite, the city may be said to have attained its greatest splendour. It continued to flourish and increase, and to be the seat of elegance and learning, until the 656th year of the Hegira (A.D. 1277), when Hulakoo the Tartar, the grandson of Genghis Khan, took it by storm, and extinguished the dynasty of the Abbassides. The Tartars retained possession of Baghdad till about the year 1400 of our era, when it was taken by Tamerlane, from whom the sultan Ahmed Ben Avis fled, and finding refuge with the Greek emperor, contrived afterwards to repossess himself of the city, whence he was finally expelled by Kara Yusef in 1417. In 1477 his descendants were driven out by Usum Cassim, who reigned 39 years in Baghdad, when Shah Ismael the First, the founder of the royal house of Sefé, made himself master of it. From that time it continued for a long period an object of contention between the Turks and Persians. It was taken by Soliman the Magnificent, and retaken by Shah Abbas the Great; and it was afterwards besieged by Amurath the Fourth, with an army of 300,000 men. After an obstinate resistance, it was forced to surrender, A.D. 1638; when, in defiance of the terms of capitulation, most of the inhabitants were massacred by torch-light. Since that period it has remained under a nominal subjection to the Turks. Achmet, the greatest of the pashas of Baghdad, and the first who rendered the pashalic independent of the porte, defended the town with such courage against Nadir Shah, that the invader was compelled to raise the siege, after suffering great loss. Baghdad, according to Colonel Chesney, had 110,000 inhabitants previously to the great plague of 1830; but now, in 1853, Mr Layard estimates its population under 50,000. Long. 44. 24. E. Lat. 33. 21. N. (Buckingham's *Travels in Mesopotamia;* Sir R. K. Porter's *Travels in Georgia, Persia, Armenia, and Ancient Babylonia;* Kinneir's *Geographical Memoir of the Persian Empire;* Chesney's *Expedition.*) (D. B—N.)

BAGHDAD is also a Turkish pashalic or government of Asia, and is computed to have an area of above 100,000 square miles. It stretches in a N.W. direction, from the mouth of the Shat-el-Arab at Bassora, to Merdin, situated near the source of the Tigris; and from the confines of Persia, W. to the banks of the Khabour, which separates it from the pashalic of Diarbekir. Its general boundaries are the Euphrates and the Arabian desert of Nedjed to the W. and S., Kusistan and Mount Zagros to the E., the pashalic of Diarbekir to the N.W., and Armenia with the territories of the Kurdish chief of Julamerick to the N. This great tract comprehends ancient Babylonia, and the greatest part of Assyria Proper. The first includes the space inclosed by the Tigris and the Euphrates, which is also known under the general appellation of Mesopotamia; and the second, that which is beyond the Tigris, commonly called Lower Kurdistan. This tract of country is an extensive and very fertile plain, and is watered by the Tigris and the Euphrates, which at Baghdad approach within 25 miles of each other, and afford an inexhaustible supply of the finest water. Only some parts of these fertile districts, however, are cultivated, as the population consists in many places of wandering Arabs, who are adverse to agriculture, and who, in their vagrant life of idleness and rapine, neglect all the natural advantages of a fertile country. The most productive portion of the pashalic is on the banks of the Shat-el-Arab, in the neighbourhood of Bassora. This tract, for upwards of 30 miles below that city, is well cultivated, and yields vast quantities of dates, wheat, barley, and various kinds of fruits. The banks of the Euphrates produce abundant crops of dry grain. Higher up the Euphrates, the country which is possessed by the Arabs is a low marshy tract, formed by the expansion of the Euphrates, and is famed for plentiful crops of rice. Among the mountainous districts of the Upper Euphrates the country is highly picturesque and beautiful; it is watered by the river Mygdonius, and is in a tolerable state of cultivation. It produces in abundance the finest fruits, such as grapes, olives, figs, pomegranates, which are esteemed the most delicious in the East; apples, pears, apricots of an inferior quality; and the finest dates, on which the inhabitants, as in other parts of Asia, depend in many cases for subsistence. The domestic animals are, the horse, for which the country has long been famed, the ass, camel, dromedary, buffalo, and mule. Of the wild animals, the lion, the hyena, the jackal, the wolf, and the wild boar, are also common; and antelopes are seen in great numbers. Hares are plentiful, but foxes are seldom seen. All sorts of poultry are bred excepting the turkey. On the cultivated lands, and on the borders of the rivers, the black partridge is met with in great numbers. Snipes and almost every species of wild fowl may be found in the marshes, and pelicans on the banks of the Euphrates and Tigris. In addition to these two rivers, the country is watered by the Khabour or Chaboras, formed by the junction of several small streams about ten miles to the S.W. of Merdin; by the Mygdonius, which joins the Khabour; and by the Hermes, a tributary of the Mygdonius.

Baghermi ‖ Bagneres-de-Bigorre.

In ancient times the plain of Mesopotamia was occupied by the great and wealthy cities of Nineveh, Babylon, Seleucia, Ctesiphon, &c., and was in a high state of cultivation. It was intersected by many well-constructed canals and other works, which, in dispersing over the country the superfluous waters of the Tigris and Euphrates, proved extremely useful to agriculture. These works are now all ruined, and not a vestige remains of many of the canals; while the course of others can only be faintly traced in their imperfect remains. One canal, however, still exists: it connects the Euphrates and the Tigris exactly half-way between Bassora and Baghdad, and is navigable in spring for large boats.

BAGHERMI. See AFRICA.

BAGLIVI, GIORGIO, an illustrious Italian physician, descended of a poor persecuted Armenian family, was born at Ragusa in 1669, and assumed the name of his adoptive father, Pietro Angelo Baglivi, a wealthy physician of Lecce. He studied successively at the universities of Salerno, Padua, and Bologna; and after travelling over Italy, he went in 1692 to Rome, where, through the influence of the celebrated Malpighi, he was elected professor of anatomy in the college of Sapienza. He died at Rome in 1707, at the early age of thirty-eight. A collection of his pieces, which are all in the Latin language, was published in 4to in 1704, and has been several times reprinted in the same form. An edition in 2 vols. 8vo was published in 1788. Baglivi's work, *De Fibra Motrice*, is the foundation of that theory of medicine which by Hoffmann and Cullen was substituted for the Humoral Pathology.

BAGMUTTY, a river of Hindustan, which has its source in the hills to the N. of Catmandoo, the capital of Nepaul, whence it flows in a southerly direction, and joins the Ganges, after a course of 285 miles, in Lat. 25. 23. Long. 86. 34.; about eight miles below the town of Monghyr, but on the opposite side of the river.

BAGNARA, a city of the province of Calabria Ulteriore II., in the kingdom of Naples, on the Gulf of Gioja. It suffered by the earthquake in 1783, when, out of 4938 persons, 3324 perished. It now contains 3000 inhabitants, who carry on a considerable trade in silk, oil, wine, and fish.

BAGNERES-DE-BIGORRE, the capital of the arrondissement of Bagneres, department of Hautes-Pyrenees, is situated on the left bank of the Adour, 13 miles S.E. of Tarbes. This is the principal watering-place in France, and is much admired for its picturesque situation and the beauty of its environs, particularly the valley of Campan,

Bagneres-de-Luchon || Bagpipe.

which abounds with beautiful gardens and handsome villas. The town is remarkably neat and clean, and many of the houses are built or ornamented with marble. Its thermal springs and baths are numerous and varied, and are very efficacious in debility of the digestive organs and other maladies. Their temperature is from 90° to 135° Fahr. The season commences in May, and terminates about the end of October, during which time the population is nearly doubled. Permanent pop. (1852) 8335. The arrondissement of Bagneres contains 10 cantons and 194 communes; pop. 95,413.

BAGNERES-DE-LUCHON, a small well-built town of France, department of Haute-Garonne, pleasantly situated in the valley of the Luchon, at the foot of the Pyrenees. It is celebrated for its sulphurous thermal springs, which vary in temperature from 88° to 152° Fahr. The principal edifice is a handsome bath establishment, erected in 1807. The waters are employed with success in a variety of chronic and cutaneous affections. Pop. about 2500.

BAGNOLES, a village of France, department of Orne, in a valley 13 miles S.E. of Domfront. It is much frequented for its mineral springs and baths, and has been much improved and embellished by handsome buildings and fine promenades. Military baths were erected here in 1822, capable of accommodating 200 invalids.

BAGNOLS, a town of Lower Languedoc, now the department of Gard, in France. It has a handsome square, adorned with a fountain, the waters of which are conveyed by a canal to the lands in the vicinity. Pop. in 1846, 3803.

BAGPIPE, a musical instrument of unknown antiquity. It was used among the ancient Mysians and Pannonians, the latter a Celtic people; and is still employed by the modern Sclavonians. The ancient Scandinavians also used it. An antique gem, of which Dr Burney procured a drawing, represents Apollo as walking with a lyre in his hands, and a bagpipe slung at his back. The bagpipe was well known to the ancient Romans, and we learn from Suetonius that Nero, among his various musical accomplishments, was a bagpipe-player. To this day the bagpipe is a common instrument in the southern parts of Italy, especially Calabria; and its modern use in Spain appears from the Spanish proverb regarding the bagpiper of Bujalance, in Andalucia, and from the allusion to the bagpipes of Zamora in chap. 62, part 2, of *Don Quixote*. Some of the mountain tribes of Hindustan are said to have a large and powerful bagpipe. Curious representations of ancient bagpipers are given in plates 33 and 34 of Gerbert's work, *De Cantu et Musica Sacra*. Court bagpipers in England are mentioned as early as the fourth year of Edward II., *i.e.* 1310. Dr Petrie, the eminent Irish antiquary, says that the bagpipe is often mentioned in Irish poems varying in date between the tenth and sixth centuries. Some Irish writers assert that the great bagpipe—the same as that of the Scottish Highlands—was used very early as a war instrument in Ireland; but the oldest representation of it which they have been able to point out is that given in *The Image of Irelande, by John Derricke. Imprinted at London by Jhon Daie*, 1581. 4*to*. The woodcut there shows a bearded and half-naked Irish piper playing upon an enormous bagpipe, with two drones and chanter. He holds the bag—as big as his own body—pressed against his stomach. Sixty years ago, several kinds of bagpipe were used in Scotland and the north of England; but we now seldom hear any others than the small Irish bagpipe, blown with bellows, and the great Highland bagpipe, or its smaller congener, which is used at dances, chiefly in the Highlands. The great Highland bagpipe is a very loud instrument, famous for its martial influence upon Highland soldiers in battle.[1] It consists of a large wind-bag made of greased leather covered with woollen cloth; a mouth-tube, valved, by which the bag is inflated with the player's breath; three reed drones, and a reed chanter with finger-holes, on which the tunes are played. Of the three drones, one is long and two are short. The longest is tuned to A, an octave below the lowest A of the chanter, and the two shorter drones are tuned each an octave above the A of the longest drone; or, in other words, in unison with the lowest A of the chanter. The scale of the chanter has a compass of nine notes, all natural, extending from G on the second line of the treble stave, up to A in alt. In the music performed upon this instrument, the players introduce among the simple notes of the tune a great number of rapid notes of peculiar embellishment, which they term *warblers*. No exact idea of these *warblers* can be formed except by hearing a first-rate player upon the Highland bagpipe. We may remark that the profusion of ornament in the music of the Highlanders reminds us of the observations made by several musical travellers upon the airs performed by various Oriental players and singers—Greek, Arab, Egyptian, Hindu, &c.—all of whom employed so many peculiar ornaments as to disguise entirely the real theme or melody, whatsoever that might be, and to produce an effect more resembling the warbling of birds than anything else generally known to Europeans.

Bahamas.

The ancient Egyptians, Greeks, and Romans, used single, double, and triple tubes, the sound of which was produced by a double reed, like that of an oboe, or of the chanter or the drone of a bagpipe, &c. The reed (γλωττὶς) was moveable, and was carried about by the the player in a box called by the Greeks γλωττοκομεῖον, *i.e.* a *tongue-case*. Demades, the Athenian orator, compared his countrymen to these reed-pipes, "good for nothing without their tongues." These tubes, called ἀυλοὶ, were blown by the mouth of the player, as seen in ancient sculptures and paintings; and required so strong a breath to sound them, that the performer bandaged up his lips and cheeks with a φορβεία, or περιστόμιον, the Roman *capistrum*, a leathern muzzle or headstall. It seems very probable that the bagpipe derives its origin from these double and triple reed-pipes, by the after addition to them of a wind-bag made of the skin of a goat or kid, together with a valved *porte-vent*, in order to relieve the strain on the lungs and cheeks of the player. In some parts of Russia, double flutes (or reed-pipes) are used among the peasantry. A paper published by George Burdett, Esq., in 1845, gives an account of a very ancient and curious instrument now peculiar to the northern parts of the island of Sardinia, and called the *lannedda*. It consisted of three reed-pipes of unequal length and thickness, and pierced with several holes, and was played upon by a vigorous Sardinian peasant eighty years of age, in a hut among the mountains about ten miles from the town of Terranova. The pipes were tuned by shifting small pieces of wax up and down outside of the holes The longest and thickest pipe was a drone, and had only one hole. The player placed the reed-ends of all these three pipes in his mouth, and sounded them all at the same time. The sound reminded Mr Burdett of that of a bagpipe. It is, he says, a very exhausting instrument, and often kills the performers at an early age. This old peasant was the last of the race of *lannedda* players. The exertion required to play upon it has caused a modification of the *lannedda* in the southern parts of the island, by adding to the pipes a common mouth-piece, like that of the double-flageolet, which greatly lessens the fatigue of the performer. (G. F. G.)

BAHAMAS, or LUCAYAS, a chain of islands stretching in a north-westerly direction from the N. coast of St Domingo to that of East Florida, and lying between Lat. 21. and 27. 30. N. and Long. 70. 30. and 79. 5. W. The group is composed of about twenty inhabited islands, and an immense number of islets and rocks. The principal islands or this group are New Providence, containing the capital, Nassau; Harbour Island; Abaco; Eleuthera; Heneagua, or

[1] See *Wood's Songs of Scotland*, vol. i. pp. 97–137, and vol. iii. p. 51.

Bahamas. Inagua; Mayaguana; St Salvador; Andros Island; Great Bahama; Ragged Island; Rum Cay; Exuma; Long Island; Crooked Island; Long Cay; Watling's Island; the Caicos, the Turks, and the Berry Islands.

Most of these islands are situated on those remarkable flats called the Great and Little Bahama Banks, and some out of soundings in the ocean. The Great Bahama Bank is about 300 miles in length from N.W. to S.E., and 100 in breadth; and the Little Bahama is about 130 miles long. The islands have, in general, a very flat appearance, and many of them consist of mere bleak and barren rocks. The soil in those that are under cultivation is thin, and generally light and sandy, but interspersed with occasional patches of rich mould. The substratum, so far as has been ascertained, consists of calcareous rocks, composed of coral, shells, madrepores, and marine deposits hardened into solid masses. The surface stratum is a combination of debris of the rock, exuviæ, and decayed vegetable matter. Though destitute of running streams, they possess numerous springs; and by digging wells down to the level of the sea, fresh water is obtained. The productions of the soil comprehend all the varieties of a tropical climate. Provisions—such as maize, yams, sweet potatoes, &c.; and fruits, as oranges, lemons, pine-apples, cocoa nuts, &c.—are produced in abundance. There are also several species of valuable trees, as mahogany, fustic, lignum vitæ, cedars, pines, &c. Oxen, sheep, horses, poultry, and a great variety of live stock are reared; and wild hogs and agoutis are found in the woods. There are many varieties of birds, and the shores and creeks abound in turtle and excellent fish of various kinds. In the most southerly islands are salt ponds of great value.

St Salvador, one of the islands composing this chain, was the first land discovered by Columbus on his memorable voyage in 1492. At that period the Bahamas were inhabited by a mild and peaceable race of Indians, who, seduced by the arts of the Spaniards, were afterwards consigned to perpetual bondage in the mines of St Domingo, or sent to labour as divers in the pearl fisheries of Cumana. From this period the islands continued devoid of inhabitants until 1629, when New Providence was settled by the English, and held till 1641, at which time the Spaniards expelled them, but made no attempts to settle there themselves. It was again colonized by England in 1666, and again ravaged by the French and Spaniards in 1703; after which it became a rendezvous for pirates till 1718, when these were extirpated, a regular colonial administration established, and the seat of government fixed in this island. In 1781 the Bahamas were surrendered to the Spaniards; but at the conclusion of the war they were once more annexed to the British empire, to which they have ever since belonged. At the close of the American war many of the British royalists sought refuge in these islands, and colonized the principal of them, from which period we may date their gradual though slow cultivation and improvement.

In 1848 the Turks, Caicos, and Mayaguana Islands were separated from the other Bahamas, and formed into a distinct government.

This colony has lately begun to assume a state of greater prosperity than previously. According to the governor's report for the year 1851, the amount of the revenue was L.26,105, and of the expenditure L.25,068; the revenue of the preceding year being L.25,591, and the expenditure L.29,451. The unfavourable financial state of the colony in 1850 was occasioned by the repeal of the export duty on fruit, the exemption of ships engaged in the salt trade from tonnage-duty, and the diminished productiveness of a new tariff. The separation of the Turks Islands—the most productive of the salt islands, and which brought a comparatively large revenue to the Bahama government—considerably affected the finances. For some years previous to that time, the income had considerably exceeded the expenditure. The governor, in his closing speech to the Bahama legislature in March 1852, said that he did not despair of seeing the day, before finally quitting the government, when the revenue will be found nearly if not quite as large as it was before the separation of the Turks from the Bahama Islands. The value of sponge exported in 1850 was, in round numbers, L.5700; and in 1851, L.14,000; that of fruit, which in 1849 was L.8000, had increased in 1851 to L.12,600; and that of salt in 1851 was L.16,500. The salt-producing islands are rapidly increasing in importance. There are at present six of these islands, viz., Inagua, Exuma, Long Cay (Crooked Island), Rum Cay, Long Island, and Ragged Island. The number of vessels that cleared out from the several ports of the colony in 1851 was 373, registering 36,914 tons; and 363 entered inwards, of 36,038 tons. There are four lighthouses, viz., a fixed light on Hog Island, at the entrance of the harbour of Nassau; a revolving light, 160 feet above the level of the sea, on the S.E. point of the Island of Abaco; a revolving light, 80 feet high, at Gun Cay; and a fixed light at Cay Sal, 100 feet above the level of the sea. There are nine colonial custom-houses and ports of entry in the government, viz., Nassau, Abaco, Eleuthera, Harbour Island, Little Exuma, Rum Cay, Long Island, Long Cay (Crooked Island), and Ragged Island, principally for the exportation of salt, the chief staple of these islands, except the first three, from which a considerable quantity of fruit (pine-apples, oranges, &c.) is exported to England and the United States.

Bahamas.

The colony is divided into 13 parishes; and the religious bodies are Episcopalian, Presbyterian, Baptist, Anabaptist, and Methodist. There are 9 Episcopal churches, besides 11 chapels; a Presbyterian church, endowed by the legislature; 4 Methodist chapels and several preaching stations; and a capacious Baptist chapel at Nassau. In 1851 L.300 was voted by the legislature to assist in the erection of three Methodist chapels.

The educational system is under a board of management, composed of the governor and four members of the executive council. Besides a number of private schools, there are 21 schools supported by the legislature, with 37 teachers, besides assistant-teachers, pupil-teachers, and monitors. In 1851 the number of scholars was 1857, and the sum expended for educational purposes L.1650. A museum, library, and reading-room, have been established at Nassau, and are partly supported by the legislature. At Nassau there is a public dispensary for supplying medicine and medical advice gratis; and there is also in New Providence an extensive building for the reception of poor and infirm persons, lunatics, and lepers. The number of inmates in 1851 was 62.

The climate is agreeable and salubrious, being tempered by northern breezes from the continent of America. It is well adapted for those suffering from pulmonary and bronchial affections; and Nassau is resorted to by many of the wealthy inhabitants of North America to avoid the severity of the winter there. The salubrity of Nassau in particular has recently been much improved by the draining of the neighbouring swamps. The average temperature from 1st November to 1st May is 76°, and from 1st May to 1st November 84°.

By the census taken in March 1851 the population of the Bahamas was 27,519; of whom 13,747 were males, and 13,772 females. The following are the inhabited islands, with their populations according to that census:—

New Providence	8159	Ragged Island	347
Harbour Island	1840	Andros Island	1030
Eleuthera (including Spanish Wells and Cays)	4610	Great Bahama	922
Rum Cay	858	Berry Islands	236
Crooked Island	1092	Bimini and Gun Cay	150
St Salvador	1828	Watling's Island	384
Exuma	2027	Inagua	530
Long Island	1477	Green Cay	7
Abaco	2011	Cay Sal	11

Bahar.

The number of births during the year 1851 was 1206; of deaths, 576. What is termed the "wrecking system" is a source of considerable profit to a large number of the inhabitants. These "wreckers" are licensed by the government, for the purpose of affording succour to vessels in distress, and rescuing lives and property from stranded ships. They are allowed a salvage on the property they recover; and, according to a recent enactment of the Bahama government, it is declared "that the wrecking vessel engaged in saving lives shall be awarded salvage on the wrecked property in equal proportion with vessels of the same size engaged in saving such property." (*Parliamentary Papers.*)

BAHAR, one of the territorial divisions of Hindustan included with the provinces of Bengal and Orissa in the dewanny or grant conferred upon the East India Company by Shah Alum, emperor of Delhi, in 1765. The province comprises the British districts of Patna, Bahar, and Shahabad, on the right bank of the Ganges, and an equal extent of territory on the left bank, now distributed between the two districts of Sarun and Tirhoot. The area is computed at 22,005 square miles, and its population amounts to 9,672,000. The tract is well watered and highly cultivated. Its principal river is the Ganges, joined on the right side by the Kurumnassa, Sone, Phalgu, and Poompun; and on the left by the Gogra, Gunduck, and Bagmutty. According to Hindu legend, Bahar comprised the dominions of the kings of Magadha, who are stated to have been lords paramount of India, and whose court is represented as one of the most brilliant that ever existed. Their highest point of grandeur is supposed to have been attained about the time of Seleucus Nicator, one of the immediate successors of Alexander the Great. In the sixteenth century, during the reign of the Emperor Akbar, Bahar constituted one of the fifteen grand divisions or viceroyalties into which India was then distributed.

The present British district of the same name is situate in the southern quarter of the province, of which it comprises about one fourth part, both in its extent and the amount of its population; its area being 5694 square miles, and its population being computed at 2,500,000. Though in general level and marshy, the district is in some parts intersected or bounded by ranges of mountains. One of these ridges extending along its southern frontier, has an elevation of 1000 or 1200 feet above the level of the sea. Another range, called by Major Rennell the Caramshaw Hills, rises on the west side of the river Phalgu; and a more considerable series termed the Rajahgriha Hills, having an elevation of 800 or 900 feet, intersects a portion of the district from N.E. to S.W. Rice, wheat, sugar, indigo, cotton, the ordinary grains of the country, and opium, constitute the staple produce. The cultivation of opium is controlled and regulated by the government, no one being allowed to grow the poppy, except on account of the state; and annual engagements are entered into by the cultivators to sow a specified breadth of land with that plant, and to deliver the whole produce, in the form of opium, to the government agents at a fixed price. Europeans have introduced the potato, which is now extensively grown. The manufacturing industry is of importance, and extends to the production of fabrics of cotton, silk, and muslin, blankets, carpets, coarse cutlery, and hardware, leather, ornaments in gold, silver, and glass, saltpetre, soap, and a variety of other articles. Coal has been discovered at the south-western angle of the district at Deori, on the right bank of the River Sone. Hindee, one of the languages derived from the Sanscrit, is the vernacular; but Hindustanee or Oordoo, a language formed from the fusion of Persian and Arabic with Hindee, is commonly spoken by the Mahometan population. Behar, the chief town, is distant from Patna 37 miles, and from Calcutta 255. Lat. 25. 10. Long. 85. 35. (E. T.)

Bahawulpoor || Bahrein.

BAHAWULPOOR, a town in Northern India, the principal place of a native state of the same name, is situate on a branch of the Ghara, forty-five miles above the confluence of that river with the Chenaub. The territory of which this town is the capital, originally formed part of the province of Moultan, and was held in feudal tenure from the Duranee monarch of Kabul. But when Runjeet Singh, the ruler of the Punjaub, brought Moultan under his authority, the Nawaub of Bahawulpoor, alarmed for his own safety, tendered his allegiance to the British. No encouragement was given to the proposal; but under the treaty of 1809 the Sutlej became the boundary of Runjeet's dominions, and Bahawulpoor was thus protected from invasion. Thirty years later, the British government undertook to restore Shah Shujah to the throne of Kabul; and as it then became desirable to fix positively the future relations of Bahawulpoor, it was stipulated that the Nawaub should be released from his allegiance to Kabul, and placed among the allies of the British. Good-will and cordiality towards the British invariably characterized the conduct of the Nawaub, and during the military operations beyond the Indus in 1839, the friendly feeling of the prince was strongly marked in facilitating the passage of the British troops, and in procuring the necessary supplies within his own territories. Upon the conquest of Sinde, the British government marked its sense of the Nawaub's fidelity by gratuitously restoring to him the districts of Subzulcote and Bhoong Bara, which had been wrested from him by the Ameers. On the death of the Nawaub in 1852, a contest for the succession arose between two sons of the deceased ruler. The elder, Hajee Khan, having been disinherited and subjected to imprisonment, his brother, Sadik Khan, consequently obtained the sovereign power in the first instance; but Hajee having made his escape, appeared in arms to assert his claim. Obtaining the support of many of the chiefs and people, and ultimately that of the troops, he succeeded in attaining his object and securing the person of his brother. The British government took no part in the contest, but at its close acquiesced in the recognition of Hajee Khan, interfering only to obtain a competent provision for the unsuccessful competitor, with permission for him to reside within the British territories.

The area of Bahawulpoor has been computed at 20,000 square miles, but a small proportion only of this extent of surface has been hitherto reclaimed from the desert. The fertile tract extends principally along the river line for a distance of about ten miles in breadth from the left or eastern bank, the transition from cultivation to desert being abrupt and striking. Wheat, rice, and various other grains, cotton, sugar, and indigo, form the staple crops. The population is estimated at 600,000. The Nawaub has an annual revenue of L.140,000, and maintains a military force of 13,000 men. The town is in Lat. 29. 24. Long. 71. 47. (E. T.)

BAHIA. See SALVADOR, ST.

BAHIR, a Hebrew term signifying "famous" or "illustrious," but particularly applied to a book of the Jews, treating of the profound mysteries of the Cabala, the most ancient of the rabbinical writings.

BAHREIN, the principal of a cluster of islands on the south-west side of the Persian Gulf, near the Arabian shore. This island, which is about twelve miles from the coast, is one of the finest in the gulf, and is covered with villages and date gardens. The town and fort of Manama, which contains about 800 or 900 houses, carries on a considerable trade with Bassora and other ports in the gulf. Here is a harbour admitting vessels of 200 tons, which trade to Bushire, and with a fair wind make the voyage in fourteen hours. This island has always been famous for its pearl fishery. Its banks produce the finest pearls in the world. They are found in a small mussel which is attached to the bottom by a thin fibre of great length. This is cut by the diver from a depth of three fathoms. These pearls are of two

sorts, white and yellow; and are sent to India, and through Bassora and Baghdad into Asia. The fishery is farmed out by the different chiefs on the coast, who draw a large revenue from this source. It employs annually about 2500 boats, each with from eight to fifteen men. The gains of the divers do not average more than from 40 to 50 Spanish dollars in a season. These islands once belonged to the Portuguese, and afterwards fell under the dominion of an Arabian chief, from whom they were seized by the Persians. They were afterwards taken possession of by the Wahabees. Bahrein is also the name of a province in Arabia. See ARABIA.

BAIÆ, an ancient town of Campania, in Italy, situated between the promontory of Misenum and Puteoli, on the Sinus Baianus, and famous for its warm springs and baths, which served the wealthier Romans for the purposes both of health and pleasure. The variety of these baths, the softness of the climate, and the beauty of the landscape, captivated the minds of the opulent nobles, whose passion for bathing knew no bounds. Hither retired for temporary relaxation the mighty rulers of the world, to recruit their strength and revive their spirits, fatigued with bloody campaigns and civil contests. Their habitations at first were small and modest; but increasing luxury soon added palace to palace with such expedition, that ground could no longer be found for new erections; while enterprising architects, supported by boundless wealth, carried their foundations into the sea, and drove that element back from its ancient limits. From being a place of occasional resort for a season, Baiæ grew up into a regular city, and the confluence of wealthy inhabitants rendered it as much a miracle of art as it had before been of nature. Its great splendour is still attested by innumerable ruins, heaps of marbles, mosaics, stucco, and other precious relics of the past. It flourished in undiminished magnificence till the days of Theodoric the Goth; but the destruction of these enchanted palaces followed quickly upon the irruption of the northern conquerors, who overturned the Roman power, sacked and burned all before them, and destroyed or dispersed the whole race of nobility. When the guardian hand of man was withdrawn, the sea rushed back upon its old domain; moles and buttresses were torn asunder and washed away; and promontories, with the proud towers that once crowned their brows, were undermined and tumbled into the deep. Yet, in its ruined state, and stripped of all its ornaments, Baiæ still presents many striking objects for the admiration of the traveller and the pencil of the artist. Long. 14. 3. E. Lat. 40. 50. N.

BAIBOUT, a town of Asiatic Turkey, in the pashalic of, and 65 miles W.N.W. from Erzroum. This was one of the strongholds of the Genoese, when prosecuting their trade with India. Remains of their fortifications still exist. Pop. about 3000.

BAIER, or BAYER, *Gottlieb Siegfred*, an eminent German philologist and antiquarian, born at Königsberg in 1694. Of his various writings, the principal is that entitled *Musæum Sinicum*, a very curious and able work. He died at St Petersburg in 1738.

BAIKAL, a great lake of Siberia, in the government of Irkutsk, 366 miles in length from S.W. to N.E., and from 20 to 53 miles in breadth. This vast reservoir is 1200 feet above the level of the sea. It is fed by several large rivers, namely, the Upper Angara, Selenga, Barguzin, and others; while the only visible outlet is by the Lower Angara, which is incapable of carrying off anything like the quantity of water which is received. The water is excellent, and extremely clear, so that the bottom can be seen at the depth of 8 fathoms. The depth of the lake varies from 22 to upwards of 300 fathoms. It yields abundance of fish, and there is a profitable fishery of seals on its shores during the whole summer; but the species is not ascertained. The climate is extremely severe: the waters of this great inland sea are frozen over from November, and the ice does not break up till May. This lake facilitates the Russian trade with China, and that between Irkutsk and Dauria. It is navigated by the Russians in summer, and in winter they travel across it on the ice. Steam-vessels were introduced here in 1844. Several hot springs and mineral waters are seen on the margin, and naphtha is sometimes found floating on the surface. It is between 51. 20. and 55. 30. N. Lat. and 103. and 110. E. Long. The island of Olkhon, near its north shore, is 32 miles long, and nearly 10 broad.

BAIL, BALLIUM (from the French *bailler*, which is derived from the Greek *βαλλεῖν*, and signifies to deliver into hands), is used in our common law for the freeing or setting at liberty of one arrested or imprisoned upon any action, either civil or criminal, on surety taken for his appearance at a certain day and place.

BAILEN, a town of Spain, in the province of Jaen, and *partido* of Carolina, six leagues N.N.W. of Jaen. Pop. 4976. This is the ancient Bæcula, where Scipio gained a signal victory over Hasdrubal, B.C. 209, and over Mago and Masinissa, B.C. 206 (Polyb. x. 38, xi. 20; Liv. xxvii. 18–20, xxviii. 13.) In the Epitome of Livy, however, the place is called *Bætula*. Near this also, in 1212, was fought the great battle of Navas de Tolosa, where Alonso VIII. is said to have left 200,000 Moors dead on the field, with the loss of only 25 Christians! Here again, on the 23d of July 1808, the French general Dupont, after a bloody contest of several days, signed the *Capitulation of Bailen*, by which 17,000 men were delivered up to the Spaniards as prisoners of war. This disaster was the first great blow to the French arms in the Peninsula. (Madoz, *Diccionario;* Ukert, vol. x. p. 379.)

BAILEY, or BAILY, *Nathan*, an eminent English philologist and lexicographer, whose *Etymological English Dictionary* may be regarded as the basis of Johnson's unrivalled work. He had a school at Stepney, near London; and was the author of *Dictionarium Domesticum*, and several other works. He died in 1742.

BAILIE, the title of a class of magistrates of the second rank in the burghs of Scotland, corresponding generally, though not in all respects, with the aldermen of England. In the royal burghs they seem to have been originally the stewards or executive officers of the crown; in the inferior burghs, of the barons or feudal superiors. At common law the magistrates of royal and parliamentary burghs are held to possess the same powers within their territory as the sheriff in his county; but the powers of bailies of baronies are now so limited as to be scarcely worth exercising, and have fallen generally into disuse.

BAILIFF, or BAILIE, in a general sense, denotes an officer appointed for the administration of justice in a certain district or bailiwick. The term is formed from the French word *bailif*, that is, *præfectus provinciæ*. The chief magistrates in some towns are called bailiffs or bailies; and sometimes the persons to whom the king's castles are committed are termed bailiffs, as the *bailiff of Dover Castle*.

Of ordinary bailiffs there are several sorts, viz., sheriffs' bailiffs, bailiffs of liberties, &c. Sheriffs' bailiffs, or sheriffs' officers, are either bailiffs of hundreds or special bailiffs. Bailiffs of hundreds are officers appointed over those districts by the sheriffs, to collect fines, to summon juries, to attend the judges and justices at the assizes and quarter-sessions, and also to execute writs and process in the several hundreds. Bailiffs of liberties were those bailiffs appointed by every lord within his liberty, to execute process, and do such offices as the bailiffs-errant were wont to do at large in the county.

BAILII, or BAILLY, *David*, a painter of perspective views and portraits, was the son of Peter Bailii, an artist of some note, and was born at Leyden in 1588. From his father

Bailiwick ‖ Baillie.

ne learned to draw and design. He afterwards studied under Adrian Verburg, and then under Cornelius Vandervoort, with whom he spent about six years. Vandervoort possessed many capital paintings of some great masters, which Bailii, for his own improvement, copied with great care. One perspective view of the interior of a church, by Stenwyck, he finished with such accuracy, that Stenwyck himself could scarcely determine which of the two was the original. After this he travelled in Italy, and spent some years at Rome. In the latter part of his life, he devoted himself to portraits drawn with the pen, which are characterized by great force and roundness. He died in 1638.

BAILIWICK (*bailli*, and the Saxon *wic*, a *village*), that liberty which is exempted from the jurisdiction of the sheriff of the county, and over which liberty the lord thereof appoints his own bailiff, with the like power within his precincts as an under-sheriff exercises under the sheriff of the county. Or it signifies the precinct of a bailiff, or the place within his jurisdiction.

BAILLET, ADRIEN, a very learned French writer and critic, born in June 1649, at the village of Neuville, near Beauvais, in Picardy. His parents were too poor to give him a proper education, which, however, he obtained by the favour of the bishop of Beauvais, who afterwards presented him with a small vicarage. In 1680 he was appointed librarian to M. de Lamoignon, advocate-general to the parliament of Paris, of whose library he made a *Catalogue Raisonné* in thirty-five volumes folio, all written with his own hand. He died in January 1706. In the list of his numerous works, the following are among the most conspicuous :—1. *Histoire de Hollande depuis* 1609 *jusqu' à* 1690, 4 tom. 12mo, a continuation of *Grotius*, and published under the name of Neuville. 2. *Les Vies des Saints*, 3 tom. fol. 3. *Des Enfants devenus célèbres par leurs Etudes et par leurs Ecrits*, 2 tom. 12mo. 4. *Vie de Descartes*, 2 tom. 4to. 5. *Jugemens des Savants sur les principaux Ouvrages des Auteurs*, 9 tom. 12mo. The last is the most celebrated and the most useful of all the works of this learned and indefatigable writer. The edition of it published in 1722 by M. de la Monnoye, in seven volumes quarto, contains the *Anti-Baillet* of M. Menage, besides notes ; but the edition published at Amsterdam in 1725 is more esteemed.

BAILLEUL, an ancient town of France, department Du Nord, near the Belgian frontier. It was formerly a place of great strength. Pop. 5988. Lat. 50. 45. N. Long. 2. 44. E.

BAILLIE, JOANNA. This very amiable and accomplished lady was born at Bothwell, on the banks of the Clyde, in 1762. A niece of William and John Hunter, and a sister of Dr Matthew Baillie, she shared the talents of this distinguished family, and increased its honours by a pure and elevated poetry, which has added another wreath to the laurels of her country. She appears early to have cultivated her poetic taste, but did not come before the public as a poet until 1798, when she produced a volume of *Plays on the Passions*, which at once established her powers in delineating character, and exhibited originality of invention. The public was not slow in acknowledging her genius, and hailed with satisfaction the appearance of a second volume, on the same plan, in 1802.

Though the design of each play was chiefly to illustrate a single motive of action, Miss Baillie showed tact in giving variety to her compositions, and especially excelled in the delicate discrimination of the peculiarities of female characters. Although her plays were intended rather for the closet than the stage, the enthusiastic admiration of the two greatest tragedians of our age, Mrs Siddons and John Kemble, introduced *De Montfort* successfully on the English stage ; and another of her plays, *The Family Legend*, was a favourite piece in the theatre of Edinburgh, where it was introduced by a prologue by Walter Scott, and followed by an epilogue by Mackenzie, the author of *The Man of Feeling*. The subjects of her plays are not historical, but are ideal combinations of character, given with a dignity and force that stamp them as the conceptions of a pure and vigorous mind. Though of unostentatious and retiring habits, her friendship was eagerly sought and cultivated by some of the most distinguished literary characters of the age ; and Scott has thus happily expressed his admiration of Joanna Baillie :— Baillie.

> " When she the bold enchantress came
> With fearless hand and heart on flame,
> From the pale willow snatch'd the treasure,
> And swept it with a kindred measure ;
> Till Avon's swans, while rung the grove
> With Montfort's hate, and Basil's love,
> Awakening at the inspired strain,
> Deem'd their own Shakspeare liv'd again."

Her principal productions are *De Montfort*, *The Family Legend*, *Count Basil*, *Henriquez*, and *Separation*. We have already stated the favourable circumstances that introduced the first two on the stage ; the last two have also since been acted. Another volume containing her minor poems, in which are some good specimens of humorous song, showing her talent for lighter compositions, has more lately been given to the public. A collective edition of her works, in one volume, was published at London in 1851.

Miss Baillie's modest retreat at Hampstead was long a favourite resort of those individuals whom she honoured with her friendship ; and till within a short period of her death, she was able to receive her friends, and even to correspond with a select few. There this accomplished and estimable woman closed her long career, on the 23d of February 1851. (T. S. T.)

BAILLIE, *Dr Matthew*, was the son of the Rev. James Baillie, who was successively the clergyman of the parishes of Shotts, Bothwell, and Hamilton, in Lanarkshire, and afterwards professor of divinity in the University of Glasgow. The acknowledged influence of the female parent in forming the character of her offspring may be here admitted. His wife was Dorothea, the intellectual sister of the celebrated William and John Hunter ; their son, Matthew, became one of the most distinguished anatomists and physicians of the age ; and their daughter, Joanna Baillie, added fresh lustre to the poetic genius of Scotland.

The subject of this notice was born in the manse of Shotts in 1761, and was for several years a student in the University of Glasgow, where he became a pupil of Dr Reid in moral philosophy. His professional career was determined by the advice of his maternal uncle, Dr William Hunter, who undertook to superintend his education. On his father's death, a Glasgow exhibition to Balliol College, Oxford, was obtained for him, and he remained a year in that celebrated seat of learning before he removed to London, where he enjoyed the advantages of his uncle's personal direction of his studies. In two years more he assisted Dr Hunter in his anatomical lectures as his assistant and demonstrator, visiting Oxford occasionally, so as to keep his terms to qualify for the degree of bachelor of medicine. Dr Hunter, at his death, bequeathed the use of his magnificent collections to his nephew, together with the lecture-rooms in Windmill Street, an annuity of L.100 a-year, and a small family estate in Scotland ; which last was resigned by Baillie to his other uncle, John Hunter, whom he considered as the natural heir.

Within two years after Dr Hunter's death, his nephew became the principal teacher in that celebrated school of anatomy ; and in 1787, although only a bachelor of medicine, he was appointed physician to St George's Hospital, where he soon distinguished himself by the precision and accuracy of his diagnosis, and the sagacity of his treatment of dis-

Baillie. ease, which speedily introduced him to respectable private practice.

In 1789 he married Sophia, daughter of the eminent accoucheur Dr Denman; a connection which favoured his introduction to practice among the first circles in London, for which, however, he was still more indebted to his talents, his high character, and his unassuming manners. The fine collections of his two uncles became his careful study; and to render them more useful to the public, he gave to the world, in 1795, the result of his examination of them, and of his own experience, in his *Morbid Anatomy*, a most valuable work, which was speedily translated into French, Italian, and German, the latter by no less distinguished an anatomist than Soemmering. After this, Oxford did itself honour by enrolling Matthew Baillie among its doctors of medicine; and he became a Fellow of the Royal College of Physicians.

Dr Baillie was eminently distinguished by his profound knowledge of his profession, his sagacity, his very perspicuous and decided mode of explaining his views of the nature of a disease, his uniform courtesy to his professional brethren, his kindness of manner to his numerous patients, and his delicate attention to the feelings and cases of the poor who applied to him for advice, at a time when the rich and the noble, and even royalty itself, made large demands on his time and medical services. In person Dr Baillie was slender, and rather diminutive; but his mind was expanded, his intellect of the first order; his manners were kind and courteous, and perfectly unassuming; his benevolence extensive and unostentatious; and probably no physician who ever practised in London was more universally respected, or more sincerely regretted, than Dr Matthew Baillie at the period of his decease, which took place on the 23d of September 1823, in the 63d year of his age. The second edition of the *Morbid Anatomy* appeared in 1797; and two years afterwards it was illustrated by a 4to volume of engravings, with excellent descriptions of the plates. Two years after his death, appeared his *Anatomical Lectures and Medical Observations*. The *Works*, 2 vols. 8vo, edited, with a biographical sketch, by Mr Wardrop, contain only the *Morbid Anatomy* and miscellaneous medical papers. (T. S. T.)

BAILLIE, Robert, one of the most learned men among the Scottish presbyterians of the seventeenth century, was born at Glasgow in the year 1599. His father, who is described as a citizen, was a son of Baillie of Jerviston, who belonged to the family of Carphin, a branch of the ancient family of Lamington, in the county of Lanark; his mother was Helen Gibson, connected with the Gibsons of Durie, one of whom was an eminent judge in the supreme court. In the year 1617 he was matriculated in the university of Glasgow, under the name of *Robertus Baillize;* and here it may be remarked that, according to the careless practice of the age, he afterwards exhibited no small variety in the orthography of his surname, writing it Baylie, Baily, Bailie, and Baillie. His studies were partly conducted under the superintendence of John Cameron, a man of great learning and reputation, who had been a professor in the protestant university of Saumur, and who in 1622 was appointed principal of the university of Glasgow. From him Baillie imbibed the doctrine of passive obedience; and, in consequence of this prejudice of education, he only gave a tardy assent to the strenuous measures which were afterwards adopted against Charles the First. Having taken the degree of A. M. he applied himself to the study of divinity, and in due time received ordination from Archbishop Law.

On the 16th of August 1626 he was admitted one of the regents of the university; and, on taking his chair, he delivered an inaugural oration *De Mente agente*. Dr Strang, a man of talents and learning, had been appointed principal a few months before. About the same period, Baillie appears to have prosecuted the study of the oriental languages, in which he is allowed to have attained to no mean proficiency. He was anxious to promote similar studies in the university; and in the year 1629 he delivered an oration *In Laudem Linguæ Hebrææ*. Baillie.

One of the pupils intrusted to his charge was Lord Montgomery, eldest son to the earl of Eglintoun, by whom he was presented to the living of Kilwinning in Ayrshire. His induction must have taken place between 1630 and 1632. With this noble family he continued to live on terms of intimacy; and as he was a person of excellent character, he equally enjoyed the approbation of his own parishioners, and the confidence of his ordinary the archbishop of Glasgow. In 1633 he declined the offer of a living in Edinburgh. Between 1634 and 1636 he was much employed in discussing, by means of private correspondence with his brethren, certain questions respecting Arminianism, and the ceremonies obtruded on the church by the partisans of Laud. In 1638 the presbytery of Irvine elected him a member of the assembly which was held at Glasgow, and which laid the foundation of material changes in church and state. During the ensuing year his countrymen raised a considerable army, which was placed under the command of Alexander Leslie, an old and experienced officer; and Baillie appears to have caught some portion of the military ardour which now prevailed in this cause of religion and liberty. "It would have done you good," he remarks in one of his letters, "to have cast your eyes athort our brave and rich hills as oft as I did, with greater contentment and joy; for I was there among the rest, being chosen preacher by the gentlemen of our shire, who came late with Lord Eglinton. I furnished to half a dozen of good fellows, muskets and pikes, and to my boy a broad sword. I carried myself, as the fashion was, a sword, and a couple of Dutch pistols at my saddle; but, I promise, for the offence of no man, except a robber in the way; for it was our part alone to pray and preach for the encouragement of our countrymen, which I did to my power most chearfully." (*Letters*, vol. i. p. 174.) He afterwards states, "Our soldiers grew in experience of arms, in courage, in favour, daily. Every one encouraged another. The sight of the nobles, and their beloved pastors, daily raised their hearts. The good sermons and prayers, morning and evening, under the roof of heaven, to which their drums did call them for bells; the remonstrances very frequent of the goodness of their cause; of their conduct hitherto, by a hand clearly divine; also Lesly's skill, and prudence, and fortune, made them as resolute for battle as could be wished. We were feared that emulation among our nobles might have done harm, when they should be met in the field; but such was the wisdom and authority of that old, little, crooked soldier, that all, with an incredible submission, from the beginning to the end, gave over themselves to be guided by him, as if he had been great Solyman....Had you lent your ear in the morning, or especially at even, and heard in the tents the sound of some singing psalms, some praying, and some reading Scripture, ye would have been refreshed. True, there was swearing, and cursing, and brawling, in some quarters, whereat we were grieved; but we hoped, if our camp had been a little settled, to have gotten some way for these misorders; for all of any fashion did regret, and all promised to do their best endeavours for helping all abuses. For myself, I never found my mind in better temper than it was all that time since I came from home, till my head was again homeward; for I was as a man who had taken my leave from the world, and was resolved to die in that service without return." This enthusiastic army had advanced to the borders of the kingdom, and had pitched its camp on Dunse Law; the royal forces were

Baillie. within a very short distance; and the adverse parties were on the eve of a general engagement, when the treaty of Berwick, negociated with Charles in person, produced a temporary cessation of open hostilities. But the seeds of dissension were too widely scattered, and had taken too deep root, to be so speedily checked in their growth: the notions of the king, sufficiently arbitrary in themselves, were at variance with the elastic spirit of the age; and his subjects, in both divisions of the island, were gradually impressed with a deep conviction of his insincerity. In the year 1640 the Covenanters again had recourse to arms; and having invaded England, they took the town of Newcastle. Baillie now resumed his attendance in the camp; and before the close of the year he was employed in London, along with other commissioners, in preparing charges against Archbishop Laud, for the innovations which he had obtruded on the church of Scotland. He had very recently published *The Canterburian's Self-Conviction*, which seems to have been industriously circulated, and which arrived at a fourth edition. About this period of his life he composed various other works of a controversial nature, and was regarded as one of the most strenuous defenders of the presbyterian cause.

His merit was now so conspicuous that he was offered a professorship in each of the four universities. Having been appointed one of the professors of divinity at Glasgow, he delivered, on the 6th of July 1642, an inaugural oration *De Hæreticorum Autocatacrisi*. About this period he must have taken the degree of D. D.; for the records of the university describe him as "Doctor et Professor SS. Theologiæ." His colleague David Dickson, who had been appointed in 1640, is described in the same manner; but neither of them assumed the title of doctor in his printed works. Both professors discharged the functions of clergymen in the city; and in such of his publications as bear the author's name, Baillie styles himself minister at Glasgow, or minister of the gospel at Glasgow, without any addition. While he filled this chair, it is to be inferred that his chief employment consisted in teaching the oriental languages. Dr Dickson having been removed to the university of Edinburgh, he was admitted to the higher professorship of divinity on the 17th of January 1651. His labours were various and extensive. He was much engaged in the public affairs of the church, and was a member of all the general assemblies from 1638 to 1653, with the exception of those which were held during his attendance at Westminster. In 1642 the assembly appointed him to visit and preach in the north of Ireland during four months. To the assembly of Westminster, which commenced its sittings in the year 1643, the church of Scotland sent Alexander Henderson, Robert Douglas, Samuel Rutherford, Robert Baillie, and George Gillespie, together with three ruling elders, the Earl of Cassilis, Lord Maitland, and Sir Archibald Johnston of Warriston. Of the proceedings of this ecclesiastical council, Baillie has given an interesting account in his correspondence. His modest opinion of himself, and his high estimate of his colleagues, are equally conspicuous. "These things are so high, and of so great concernment," he remarks in a letter to Robert Blair, "that no living Baillie. man can think Mr Henderson may be away; and to put him to go and return, it were very hard to venture such a jewel, that is so necessary to the well-being both of church and state of all these dominions. Mr Samuel, for the great parts God has given him, and special acquaintance with the question in hand, is very necessary to be here. ...Mr G. Gillespie, however I had a good opinion of his gifts, yet I profess he has much deceived me. Of a truth there is no man whose parts in a publick dispute I do so admire. He has studied so accurately all the points ever yet came to our assembly, he has gotten so ready, so assured, so solid a way of publick debating, that however there be in the assembly divers very excellent men, yet, in my poor judgement, there is not one who speaks more rationally, and to the point, than that brave youth has done ever; so that his absence would be prejudicial to our whole cause, and unpleasant to all here that wishes it well." (*Letters*, vol. i. p. 451.) In 1645 he returned from England, in order to give to the general assembly an account of the proceedings at Westminster; and having resumed his station among the assembled divines, he continued to reside for some time longer in the English metropolis.[1] He now stood very high in the esteem and confidence of his countrymen; and in 1649 he was one of the commissioners sent to Holland for the purpose of inviting Charles II., and of settling the terms of his admission to the government. In the controversy which prevailed among the presbyterians between 1650 and 1660, he adhered to the party of the Resolutioners against that of the Protesters. The commission of the general assembly had adopted two *resolutions*, by which they consented to the repeal of the act for reforming the army, and the act by which certain classes of persons were excluded from places of power and trust, on account of their immoral conduct, or of the opposition which they had evinced towards the cause of civil and religious reform; and the resolutions having been approved by two subsequent assemblies, a formal *protest* against the constitution and proceedings of those assemblies was entered by various ministers and elders.

After the restoration, Patrick Gillespie, who had enjoyed the special favour of Cromwell, was ejected from his office; and on the 23d of January 1661 Baillie was admitted as principal of the university of Glasgow. For this promotion he was indebted to Lauderdale, who had not yet appeared in his true and hideous colours. According to some writers, he might have exchanged his academical office for a bishopric; but he was deeply grieved at the establishment of episcopacy, and would not accept of preferment in the church. When the new archbishop of Glasgow, Andrew Fairfoul, arrived at his metropolitan seat, he did not fail to pay his respects to the learned principal. Baillie admits that "he preached on the Sunday, soberly and well." "The chancellor, my noble kind scholar," he afterwards states, "brought all in to see me in my chamber, where I gave them sack and ale the best of the town. The bishop was very courteous to me. I excused my not using of his styles, and professed my

[1] The following passage occurs in a letter, dated at Glasgow on the 22d of August 1654, and addressed to the famous Dr Fuller: "Haveing lately, and but lately, gone through your Holy Warr and Description of Palestine, I am fallen so in love with your pen, that I am sorie I wes not before acquaint with it, and with your self, when from the 1643 to 1647 I lived at Worcester house, and preached in the Savoy, that then, when I had some credite there, I might have used my best endeavours to have done yow pleasure." (Baillie's *MS. Letters*, vol. iv. p. 423.) Of the pulpit-oratory, and of the general talents of the Scotish divines who visited London, the Earl of Clarendon and Mr Hume have given the same unfavourable account; but on this subject, as well as on many others, their opinion is strongly contested by Mr Brodie. "These famous divines preached as chaplains, by turns, in one of the lecture-rooms; and, as was to have been expected at such a juncture from men of their reputation, capacity, and profound as well as varied erudition, they drew immense crowds. If we may form an estimate of their pulpit-oratory from their works, we may safely pronounce that the English did not discredit themselves by flocking to hear such preachers." (*History of the British Empire*, vol. iii. p. 41.)

Baillie. utter difference from his way, yet behoved to intreat his favour for our affairs of the college; wherein he promised liberally. What he will perform, time will try." (*Letters*, vol. ii. p. 461.) According to another account, the archbishop visited him during his illness, and was accosted in the following terms:—"Mr Andrew, I will not call you my Lord. King Charles would have made me one of these lords; but I do not find in the New Testament that Christ has any lords in his house." In other respects he is said to have treated the prelate very courteously; and it may not be superfluous to remark, that this mode of using the Christian name instead of the surname was not unusual at that period. Baillie died in the month of July 1662, at the age of sixty-three.

His first wife was Lilias Fleming, of the family of Cardarroch, in the parish of Cadder, near Glasgow. Of this marriage there were many children, but only five survived him. 1. Henry, a clergyman, who was never beneficed. His posterity inherited the estate of Carnbroe, which was recently sold by General Baillie. 2. Lilias, married to Eccles of Kildonan in Ayrshire. 3. Helen, married to a bailie of Glasgow, named Colquhoun. 4. Elizabeth, married to Mr Hamilton, a gentleman of Strathbane in the kingdom of Ireland. 5. Mary, married to Walter Buchanan of Orchard. The mother of these children died on the 7th of June 1653, after a lingering illness. She is mentioned by her husband in terms of much respect and affection. On the 1st of October 1656 he married Mrs Wilkie, who was a widow, and the daughter of Dr Strang. The issue of this marriage was Margaret, who became the wife of Walkingshaw of Borrowfield.

Wodrow, the zealous and faithful historian of the persecuted church of Scotland, has formed a very high estimate of Baillie's literary character. "Mr Robert Baillie may most justly be reckoned among the great men of this time, and was an honour to his country, for his profound and universal learning, his exact and solid judgement, that vast variety of languages he understood, to the number of twelve or thirteen, and his writing a Latin style which might have become the Augustan age."[1] This commendation of his Latinity may admit of some abatement; for although he evidently possessed a very familiar knowledge of the language, his Latin style cannot safely be said to reach the standard of ancient purity and elegance. An episcopalian writer, the author of the Appendix to Spotswood, has commemorated Baillie as "a learned and modest man: though he published some very violent writings, yet those flowed rather from the instigation of other persons, than his own inclinations."[2] Mr Brodie, a recent historian of much ability and research, bestows the following commendation on Baillie and his associates. "The clergy, on whom they greatly depended, were profound scholars, and no despicable politicians. Nothing can be more misplaced than the ridicule which has been so profusely levelled at that body. They proved themselves ambitious; but, to be satisfied of their talents, and to admire their knowledge, it is only necessary to peruse their works. The writings of Baillie, even his familiar letters, breathe a manliness of spirit, and evince intelligence and erudition, that must for ever rescue from contempt a class of which he did not conceive himself entitled to rank at the head."[3] Baillie. Baillie had devoted much attention to the study of the oriental languages, and was skilled in Hebrew, Chaldee, Syriac, Samaritan, Arabic, and Ethiopic. In his correspondence with the scholars of the continent, he urged Golius, Buxtorf, and other learned men, to compose elementary works on such of these languages as were not already provided with them. In an unpublished letter, dated at Glasgow on the 27th of August 1656, and addressed to Mr Crawford, a minister of London, he remarks, "The reason of my calling to you at this tyme is my desyre to know the condition of that excellent book, the best to me that ever was printed, Dr Walton's Polyglott Bible." He was solicitous that the learned protestants should undertake an Encyclopædia of arts and sciences; and urged his correspondents not to permit the education of youth, and the composition of books for elementary instruction, to be so generally engrossed by the Jesuits.

Of Baillie's publications, the following is as complete a list as we have been able to furnish.

1. Ladensium Αυτοκαταχρισις, the Canterbvrians Self-Conviction; or, an evident Demonstration of the avowed Arminianisme, Poperie, and Tyrannie of that Faction, by their owne confessions: with a postscript to the personat Jesuite Lysimachus Nicanor,[4] a prime Canterburian. *Written in March, and printed in Aprile*, 1640, 4to.—This book was speedily reprinted at Amsterdam; and a "third edition, augmented by the author, with a large Supplement," was *printed for Nathaniel Bvtter*, 1641, 4to. The additional part was likewise published in a separate form, under the title of "A large Supplement of the Canterbvrian Self-Conviction." *Imprinted* 1641, 4to. A fourth edition of the work bears the title of "The Life of William now Lord Arch-bishop of Canterbvry, examined." Lond. 1643, 4to.

2. A Parallel or briefe Comparison of the Liturgie with the Masse-Book, the Breviarie, the Ceremoniall, and other Romish Ritualls.[5] Lond. 1641, 4to. Reprinted in 1661.

3. Queries anent the Service-Book.

4. An Antidote against Arminianism.

5. The Unlawfulnesse and Danger of limited Episcopacie; whereunto is subjoined a short Reply to the modest Advertiser and calm Examinator of that Treatise: as also the Question of Episcopacie discussed from Scripture and the Fathers. Lond. 1641, 4to.

6. Satan the Leader in chief to all who resist the Reparation of Sion; as it was cleared in a Sermon to the Honourable House of Commons at their late solemn Fast, Febr. 28, 1643. Lond. 1643, 4to.

7. Errours and Induration are the great Sins and the great Judgements of the Time: preached in a Sermon before the Right Honourable House of Peers, in the Abbey-Church at Westminster, July 30, 1645, the day of the monethly Fast. Lond. 1645, 4to.

8. A Dissvasive from the Errours of the Time: wherein the Tenets of the principall Sects, especially of the Independents, are drawn together in one Map, &c. Lond. 1645, 4to. Lond. 1646, 4to.

---

[1] *Wodrow's History of the Sufferings of the Church of Scotland*, vol. i. p. 128. Edinb. 1721–2, 2 vols. fol.—See the same author's *Life of James Wodrow, A. M. Professor of Divinity in the University of Glasgow*, p. 30. Edinb. 1828, 12mo.

[2] T. Middleton's *Appendix to the History of the Church of Scotland*, p. 23. Lond. 1677, fol.

[3] Brodie's *Hist. of the British Empire*, vol. ii. p. 506.

[4] The Epistle congratvlatorie of Lysimachus Nicanor, of the Societie of Jesu, to the Covenanters in Scotland; wherein is parallelled our sweet harmony and correspondency in divers materiall points of Doctrine and Practice. *Anno Domini* 1640, 4to.—The author of this Epistle was John Corbet, a Scotish clergyman, who having taken refuge in Ireland, was "hewed in pieces in the very armes of his poore wife." (Baillie's *Historical Vindication*, p. 2.) Some notices of him may be found in Burnet's *Life of Bishop Bedell*, p. 140. Lond. 1685, 8vo.

[5] Some animadversions on this work are subjoined to L. Womock's *Beaten Oyle for the Lamps of the Sanctvarie*. Lond. 1641, 4to.

Baillie.

9. An Historical Vindication of the Government of the Church of Scotland, from the manifold base Calumnies which the most malignant of the Prelats did invent of old, and now lately have been published with great industry in two pamphlets at London; the one intituled *Issachars Burden*, &c., written and published at Oxford by John Maxwell,[1] a Scottish Prelate, &c. Lond. 1646, 4to.

10. Anabaptism, the trve Fovntaine of Independency, Brownisme, Antinomy, Familisme, &c. in a Second Part of the Disswasive from the Errors of the Time. Lond. 1647, 4to.

11. A Review of Doctor Bramble, late Bishop of Londenderry, his Faire Warning against the Scotes Disciplin. Delf, 1649, 4to.—This tract was afterwards incorporated, without being reprinted, in a collection entitled *Three Treatises concerning the Scotish Discipline.* Hagh, 1661, 4to. The other two treatises are Bramhall's Fair Warning and Watson's Second Fair Warning, in answer to Baillie; and the volume likewise includes a virulent epistle by another Scottish writer, Dr Creyghton, afterwards bishop of Bath and Wells. Baillie's Review was reprinted at Edinburgh; and having been translated into Dutch, it was published at Utrecht under the inspection of Gisbert Voet.

12. A Scotch Antidote against the English Infection of Arminianism. Lond. 1652, 12mo.

13. Appendix practica ad Joannis Buxtorfii Epitomen Grammaticæ Hebrææ. Edinb. 1653, 8vo.

14. Catechesis elenctica Errorum qui hodie vexant Ecclesiam; ex nudis sacræ Scripturæ Testimoniis, in brevibus et claris Quæstionibus ac Responsionibus proposita, in gratiam studiosæ Juventutis Academiæ Glasguensis. Lond. 1654, 12mo.

15. A Reply to the Modest Inquirer.—Perhaps relating to the dispute between the Resolutioners and Protesters. This tract, together with numbers 3 and 4, we have not seen. They are all mentioned in Baillie's papers, in the possession of Dr M'Crie.

16. The Disswasive from the Errors of the Time, vindicated from the Exceptions of Mr Cotton and Mr Tombes. Lond. 1655, 4to.

17. Operis Historici et Chronologici libri duo; in quibus Historia sacra et profana compendiose deducitur ex ipsis Fontibus, a Creatione Mundi ad Constantinum Magnum. Amstelodami, 1663, fol.—Some copies have the addition of an index, with a new title bearing the date of 1668.

18. Letters and Journals; containing an impartial Account of public Transactions, civil, ecclesiastical, and military, in England and Scotland, from the beginning of the Civil Wars in 1637, to the year 1662; a period, perhaps, the most remarkable and interesting in the British History: now first published from the manuscripts of Robert Baillie, D. D. Principal of the University of Glasgow. Edinb. 1775, 2 vols. 8vo.—Some copies, bearing the same date, have a different title, which states that the Letters were "carefully transcribed by Robert Aiken." Many of them are addressed to the author's cousin-german William Spang, minister of the Scottish staple at Campvere, and afterwards of the English congregation at Middelburg in Zeeland. It was chiefly from the materials thus communicated that Spang prepared two different publications. The first is entitled "Brevis et fidelis Narratio Motuum in Regno et Ecclesia Scoticana, excerpta ex scriptis utriusque partis scitu dignissimis, per Irenæum Philalethen." Dantisci, 1640, 4to. This work only prosecutes the narrative till the first of October 1638; but he speedily reprinted it, and added a continuation to the year 1640. "Rerum nuper in Regno Scotiæ gestarum Historia." Dantisci, 1641, 8vo.—These letters were published from a copy belonging to Matthew Baillie of Carnbroe, Esq.; and the editor likewise consulted the copy preserved among the archives of the church of Scotland. The copy which belonged to the author's family is now in the possession of Dr M'Crie, to whose kindness we are indebted for the use of it, as well as for several biographical notices. This manuscript consists of four volumes in folio, and is in a tolerably good state of preservation. Baillie's Letters and Journals are of great historical value; and as the editor, besides omitting many detached passages, has suppressed a considerable number of entire letters, we beg leave to suggest, and even to urge, the expediency of a new and complete edition.

Baillie had apparently some concern in the publication of a posthumous work of his learned predecessor Robert Boyd, principal of the university of Glasgow: *In Epistolam Pauli Apostoli ad Ephesios Prælectiones supra cc.* Lond. 1652, fol. Prefixed is a life of the author by Rivet, with whom Boyd had been intimately acquainted; but the preface is subscribed with the initials R. B. A biographical notice, bearing the same signature, is prefixed to the work of his father-in-law Dr Strang, *De Interpretatione et Perfectione Scripturæ.* Roter. 1663, 4to. (D. L.)

BAILLY, JEAN SYLVAIN, a celebrated philosopher and astronomer, was born at Paris on the 15th of September 1736. He was originally intended for the profession of painting, which his family had pursued for several generations, and he even had made some progress in the art. But the bias of his mind leaned too much to literary pursuits, especially to poetry and works of imagination, to permit him to give that application which is necessary to secure success and eminence in any profession.

The friends of Bailly, who had witnessed the early dawn of his genius, saw that it was alike fitted to appear with advantage in the study of polite literature, or to shine in the walks of science; and they recommended the latter chiefly to his attention. His acquaintance with Lacaille, the celebrated geometer, commenced; and this at once decided the object of his studies, which were now almost entirely devoted to scientific investigations. The first of his labours was a calculation of the comet which appeared in the year 1759. In January 1763 he was admitted a member of the Academy of Sciences; and in the same year he published a reduction of the observations made by Lacaille in 1760 and 1761 on the zodiacal stars: an elaborate compilation, and of very extensive utility. His attention was afterwards directed to the consideration of the theory of Jupiter's satellites. Lagrange, who now pro-

[1] John Maxwell, D. D., was the son of Maxwell of Cavons in Nithsdale; and after having been beneficed at Murthlack and in Edinburgh, he became bishop of Ross in the year 1633. He was deposed and excommunicated by the assembly of 1638, and took refuge in England. In 1640 he was appointed bishop of Killala in Ireland; but the rebellion speedily ensued, and after being stript naked and severely wounded, he was again compelled to seek a place of refuge in England, and for some time he attended the king at Oxford. In 1645 he was appointed archbishop of Tuam, and died on the 14th of February 1646. The work which Baillie answered is entitled "The Burthen of Issachar: or, the Tyranical Power and Practises of the Presbyteriall Government in Scotland." *Printed in the yeare* 1646, 4to. Dr Maxwell is the author of another work, which was answered by Rutherford: "*Sacro-sancta Regum Majestas*; or, the sacred and royall Prerogative of Christian Kings." Oxford, 1644, 4to. According to Bishop Burnet, he was "a man of eminent parts, and an excellent preacher; but by his forwardness and aspiring he was the unhappy instrument of that which brought on all the disorders in Scotland." (*Life of Bishop Bedell*, p. 141.) He is mentioned and described in the Life, Diary, and Correspondence of Sir William Dugdale, p. 437. Lond. 1827, 4to.

Bailly. mised to become the first mathematician in Europe, was the formidable rival of Bailly in the competition for this prize question in 1764. The results of his investigations were collected into a treatise, which also contained the history of that part of astronomy, and were published in 1766. In 1771 appeared his interesting and important memoir on the Light of the Satellites, which was marked with a degree of precision and accuracy till that time unknown in the observations of their eclipses.

The studies of Bailly were not entirely limited to the cultivation of abstract science, nor to profound physical speculations; his genius shone with equal lustre in those departments of literature which require a discrimination of character, and no common powers of eloquence, in order to attain excellence. His *Eloges* on Charles V., Corneille, Leibnitz, Molière, Cook, Lacaille, and Gresset, were universally admired as valuable specimens of fine writing, and they added much to his reputation. The distinguished place of secretary of the Academy of Sciences became vacant in 1771; and, supported by the patronage and influence of Buffon, he offered himself a candidate. But, in this instance, he was unsuccessful. Condorcet, then rising into reputation, and supported by the active influence of D'Alembert, was preferred to the office.

In the year 1775 he published at Paris the first volume of his great work, the *History of Astronomy*, containing the history of astronomy from its origin to the foundation of the Alexandrian School; and this was followed by three volumes on the history of modern astronomy, published between 1776 and 1783. This work, which is of inestimable value, is distinguished alike for animated description, luminous narration, and interesting detail. Besides, he published, in 1777, a work entitled *Letters on the Origin of the Sciences, and of the People of Asia;* and this was followed by another series of *Letters on the Atlantis of Plato, and the Ancient History of Asia*, as a continuation of the same work. These volumes were addressed to Voltaire, with whom he had commenced an ingenious correspondence and discussion on this curious subject. The coincidence of his opinions with those of Buffon in points respecting some of the favourite theories of the latter, brought on an intimate acquaintance and close friendship with that celebrated naturalist; which, however, declined and was entirely dissolved, in consequence of the opposition which Bailly made to the election of the Abbé Maury into the French Academy. Bailly had been chosen secretary of the academy in 1784; and in the following year he was admitted into the Academy of Inscriptions and Belles Lettres. This was the only instance, since the time of Fontenelle, of the same person being at once a member of all the three academies.

In the year 1784 he was nominated one of the commission to investigate the nature of the animal magnetism of Mesmer; and he drew up a very elegant report, which was presented to the academy of Sciences. This report, which was soon afterwards translated into English, not only marked the acuteness and discernment of the author, and contained the most satisfactory and decisive evidence with regard to its object, but it may be held up as an excellent model of imitation for those who are engaged in similar investigations. In developing the physical effects produced by moral causes, it is of the greatest value; and it is particularly interesting when we consider the political influence which causes of this nature have exerted on the general opinions of society, and even on the destiny of nations.

In 1787 he published, in one volume 4to, the *History of Indian and Oriental Astronomy;* a work of great erudition and ability, but in which he is thought to have made some erroneous calculations, and to have overrated the antiquity of the Indian observations.

Hitherto we have contemplated Bailly in the shades of retirement, and in the calm undisturbed retreats of philosophy, employing the energy of a vigorous and comprehensive mind in the profound researches of physical truth. We are now to follow him in his political career, and to behold him struggling with the adverse interests of factions, and contending with the unbridled fury of a lawless mob, in defence of the rights of a people whose minds were not prepared to understand, and whose habits were not yet formed to enjoy, the blessings of rational liberty. He was one of the first and most zealous promoters of the revolution in France; and in the part which he acted in this bloody struggle, he has had the good fortune to be well spoken of by opposite factions. He has never been charged with want of integrity or with selfish designs; but apparently actuated by a misguided zeal, and dazzled with the prospect of freedom which the warmth of his imagination held out, he rashly committed himself in a cause which, as he had espoused it with enthusiasm, so he supported it with his utmost exertions. But in that cause he fell a sacrifice to the unrelenting spirit of violence and faction which had been easily roused, but which it was found impossible either to subdue or to regulate. When the states-general of France were assembled in 1789, he was elected a deputy to the *tiers-état*, of which he was afterwards chosen president; and when the national assembly had been constituted, he continued in the chair, and officiated as president at the time the king's proclamation was issued ordering that body to disperse. During the struggle which took place between the national assembly and the court, Bailly was amongst the most forward in asserting those popular rights which were then new in France; and it was he who dictated the famous oath to the members of the *tiers-état*, by which they pledged themselves "to resist tyrants and tyranny, and never to separate till they had obtained a free constitution." On the 14th of July following, the day on which the Bastille was stormed and taken by the people, he was appointed mayor of Paris with universal consent. In this high office he is allowed to have acted with great integrity, courage, and moderation, and to have discharged its arduous and sometimes perilous duties in a manner highly honourable to his character. While he held this conspicuous situation, he was instrumental in promoting the various measures by which the popular party at length prevailed over that of the court; for which, as well as for his conduct in other respects, he obtained a high degree of favour among the people. But the tide of public opinion now swelled beyond all bounds; and no restraint could oppose its violent course. The multitude, newly unshackled from the fetters of despotism, greedy of novelty, fired with enthusiastic and unsettled notions of freedom, and daily panting for change, would brook no opposition. Bailly, who now perhaps saw when it was too late the general disposition of the people to anarchy, still wished the laws to be respected, and hoped by their vigorous execution to restore and maintain tranquillity. He ordered some deputies from the military insurgents of Nancy to be arrested, and firmly opposed the rash proceedings of Marat and Hebert; he became a member of a less promiscuous club than that of the Jacobins; and he exerted himself strongly to persuade the populace to permit the king and royal family to depart to St Cloud. By these measures, which were little relished by a fickle and infuriated people, he lost their confidence and favour But what finally destroyed his popularity, was his conduct on the occasion of the tumultuous meeting of the populace on the 17th of July 1791, to demand the abolition of monarchy; for being called by the national assembly to disperse the mob, who had assaulted the soldiery, he ordered

Bailly.

Bailment ‖ Bailly.

the latter to fire, by which means forty persons were killed and above a hundred wounded. Having thus become obnoxious to the people, whom he had faithfully served, he resigned his office at the dissolution of the constituent assembly in the end of the year 1791; and having resumed his philosophical researches, lived for some time in retirement. But the times of bloody proscription approached; and he was doomed to fall a sacrifice to the ferocious vengeance of the plebeian tyrant who now bore unlimited sway. He was accordingly denounced as an enemy to the republic, arrested, and thrown into prison. Arraigned before a sanguinary tribunal, he was summarily condemned to death as a conspirator, and executed the day following, near the spot where he had given the order for the military to fire on the people. On the day of execution, his sufferings, which he bore with the utmost calmness and magnanimity, were studiously protracted. He wore the red shirt, or badge of conspiracy, and was placed in a cart with his hands tied behind his back. During the whole time of his progress to the place of execution, the rain poured incessantly on his head. The populace, as he passed, threw mud at him, and cruelly insulted him with every kind of opprobrious language. Arrived at the place of execution, it was found necessary to remove the guillotine from the spot where it had first been erected, to firmer ground. During this time he was forced to get out of the cart, and walk round the field, in order to gratify more fully the implacable and unrelenting malice of the populace. While he was ascending the platform, a spectator who happened to be near him exclaimed, in a tone of insult, "Bailly, you tremble:" "Yes," he instantly replied, "but it is from cold."

Several works written by Bailly, and found in manuscript, have been published since his death; particularly an *Essay on Fables and their History*, and *Memoirs of a Witness of the Revolution*, which come down to October 1789.

In his person Bailly was tall, and of a sedate but striking countenance. He possessed great firmness and integrity of character, combined with many amiable qualities. In the time of his magistracy he spent part of his fortune in relieving the wants of the poor. His wife, whom he married in 1787, survived him. She was the widow of Raymond Gaye, who had been his intimate friend for twenty-five years.

BAILMENT, from the French *bailler*, to deliver, means, in law, a delivery of goods in trust upon a contract, expressed or implied, that the trust shall be faithfully executed on the part of the bailee or person to whom they are delivered, and the goods re-delivered as soon as the time or use for which they were bailed shall have elapsed or been performed. There is a valuable *Essay on the Law of Bailment* by Sir William Jones.

BAILY, Francis. The history of this gentleman affords a remarkable instance of that energy with which a man successfully engaged in a laborious mercantile occupation, can devote his leisure to abstruse mathematical investigations. Mr Baily was born in Berkshire in 1774, and for many years was a stockbroker in London. While amassing a large fortune by his business, he had applied his profound mathematical knowledge to the doctrine of probabilities, and published several interesting works on that subject; as, *Tables for the Purchasing and Renewing of Leases; The Doctrine of Interest and Annuities; The Doctrine of Annuities and Assurances*, &c. In 1820 he was one of the original and most active promoters of the Astronomical Society; and on his retirement from business in 1825, he entered with all the energy of youth, rather than that of a man between fifty and sixty, into the cultivation of astronomy and its kindred sciences. To Mr Baily we owe the present form and improvement of the *Nautical Almanac*; he took an active part in the investigation of the effects of the atmosphere on the nice experiments with the pendulum; he aided in the repetition of the famous experiments of Cavendish on the specific gravity of the earth; he superintended the publication of the Astronomical Society's catalogue of the fixed stars; and the revision of the annual catalogues in the 13th volume of the Society's *Memoirs* was entirely his work. Besides these labours, he took an active share in the physical labours of the British Association. It was on his recommendation that it undertook the republication of the *Histoire Céleste* of Lalande, combined with Lacaille's catalogue, which together contain no less than 57,000 stars; and there is reason to believe that the investigations concerning the course of the tidal wave in the Atlantic owe much of their value to this able philosopher. He also superintended the construction and printing of the tables of coefficients of reduction for the 10,000 stars in the Astronomical Society's catalogue; and he had undertaken to superintend the construction of the new metrical scale for government, on the destruction of the original by fire.

Bainbridge ‖ Baird.

In fact, Mr Baily effected, in the last twenty years of his very active and useful career, a greater number of complete and refined researches than most other philosophers have accomplished during a whole lifetime. He died Aug. 30, 1844. See Sixth Preliminary Dissertation, Art. 242.

BAINBRIDGE, Dr John, an eminent physician and astronomer, born at Ashby de la Zouche, in Leicestershire, in 1582. He taught a grammar school for some years, and practised physic, employing his leisure hours in astronomy, which was his favourite study; but at length, removing to London, he was admitted a fellow of the College of Physicians, and raised his character by his description of the comet in 1618. The next year Sir Henry Savile appointed Bainbridge his first professor of astronomy at Oxford; and the masters and fellows of Merton College made him first junior, and then superior, reader of Linacre's lecture. He died in 1643. His published works are, 1. *An Astronomical Description of the late Comet*, Lond. 1619. 2. *Procli Sphæra*, 1620. 3. *Canicularia; a Treatise concerning the Canicular Days*, Oxford 1648. Several of his unpublished writings exist in manuscript in the library of Trinity College, Dublin.

BAIOLENSIANS, or Bagnolensians, a sect of heretics in the twelfth century, who in reality were Manicheans, though they somewhat disguised their errors. They rejected the Old Testament and part of the New. They were a branch of the *Cathari*, and derived their appellation from Bagnolo in Provence.

BAIRAM, a Mahometan feast, instituted in imitation of the Easter of the Christian Church. It follows the Rhamadan, or month of fasting. The lesser Bairam follows sixty days after the first.

BAIRD, General Sir David, Bart., was born at Newbyth in Aberdeenshire, in December 1757. He entered the British army in 1773, and was sent to India with the 73d Highlanders in 1779. In the following year he had the misfortune to fall into the hands of Hyder Ali, in the Mysore chief's perfidious attack on a handful of British troops at Perambucum. The prisoners, it is well known, were most barbarously treated. Baird survived his captivity; and on his release, visited his native country, but returned to India in 1791, as a lieutenant-colonel.

When Harris marched against Tippoo Saib, Baird, now a major-general, served under him in that campaign; and when it was resolved to storm Seringapatam, he solicited and obtained the honour of leading the storming party to the breach. He made a daring assault, and was soon a victor in that stronghold in which he had long been a prisoner. He seems, however, not to have been in favour with the superior powers; for he was rather unceremoniously required to resign the place his valour had contributed to gain, to a junior officer, who had not been engaged in the assault; but he received the thanks of the British parliament and of the East India Company for his gallant bearing on that im-

portant day, and being more athirst for fame than emolument, he declined the pension offered to him on that occasion by the company.

General Baird commanded the Indian army that in 1801 was sent to co-operate with Hutchinson, in the expulsion of the French from Egypt. He landed at Kosseir, conducted his army to Kenéh on the Nile, and thence to Rosetta, where he arrived just as the French were treating for the evacuation of Alexandria. Baird returned to India in 1802, where he was employed against Scindia; but, irritated at some neglect he had experienced, he relinquished his command and returned to Europe.

In 1805 he commanded the expedition against the Cape of Good Hope, and captured Cape Town; but here again, his usual ill-luck attended him, for he was recalled before he had organized his conquest, for having sanctioned the expedition of Sir Home Popham against Buenos Ayres. He served again in 1807 in the expedition against Copenhagen, and in the following year commanded the considerable force which was sent to Spain to co-operate with Sir John Moore. In the battle of Coruña, a grape-shot shattered his left arm, so as to require amputation at the shoulder-joint; and he was again thanked by the parliament of his country for his gallant services, and at last obtained the decoration of the order of the Bath, and the rank of a baronet.

Sir David married Miss Campbell Preston, a Perthshire heiress, in 1810. In 1820 he was appointed commander-in-chief in Ireland; but the same influence which had thwarted him in India, again was exerted against him, and he was removed in 1821. From that period he no more appeared in public life; and he died on the 18th August 1829. (T. S. T.)

BAIREUTH, or BAYREUTH, capital of the circle of Upper Franconia, in Bavaria, is pleasantly situated in a valley on the left bank of the Red Maine, 40 miles N.N.E. of Nuremberg. It is well built, with broad, regular, and well-paved streets; and is partially surrounded by old walls. The river is here crossed by two bridges. Among its public buildings are the modern castle, the opera-house, one of the finest in Germany, gymnasium founded in 1664, bank, riding school, and barracks. It has also five churches, a handsome synagogue, public library, theatre, hospital, an orphan and a lunatic asylum. In 1841, a monument was erected here to the poet Jean Paul Richter, who died here in 1825. Baireuth has an active trade, chiefly in grain; and manufactories of woollen and cotton goods, leather, delft, and other earthenware, and tobacco. It has also several breweries and distilleries. About half a league distant is the suburb of St George, noted for its marble works; and about two miles to the E. is the Hermitage, a fanciful building, erected in the early part of the last century, with gardens containing terraces, statues, and fountains. Pop. in 1849, 14,145.

Baireuth was formerly the capital of a principality of the same name, which, on the death of the last margrave without issue in 1791, was annexed to the kingdom of Prussia. In 1807, it was ceded by Prussia to France, which kept possession of it till 1810, when it was transferred to Bavaria.

BAIROUT. See BEYROUT.

BAITING (Saxon, *bate, contention*), the act of attacking and harassing greater and stronger animals by smaller or weaker ones, as bulls or bears by mastiffs or bull-dogs.

BAIZE, a coarse woollen stuff, in texture resembling flannel.

BAJAZET I., sultan of the Turks, commenced to reign in 1389, and died in 1403. See TURKEY, and CONSTANTINOPOLITAN HISTORY. The authority of the celebrated story of the iron cage, in which this monarch was said to have been carried about by his conqueror Timour, is considerably weakened by the silence of the Persian historian Shereffedin Ali. On the evidence on both sides of the question, see Gibbon.

BAJAZET II., son of Mahomet II., succeeded his father in 1481, and died in 1512. See TURKEY.

BAJULUS, an ancient officer in the court of the Greek emperors. There were several degrees of bajuli; as, the grand bajulus, who was preceptor to the emperor; and the simple bajuli, who were sub-preceptors. The word is derived from the Latin verb *bajulare*, to carry or bear a thing in the arms or on the shoulders; *bajulus* and *gerulus* being the names applied to those who performed this office for the children of the great; whence the subsequent figurative use of the term. The word passed in the same sense into Greece.

BAKER, a person whose occupation or business it is to bake bread. There is considerable doubt as to the time when baking first became a particular profession, and bakers were introduced. It is, however, generally agreed that they had their rise in the East, and passed from Greece to Italy about the year B.C. 173. Till that time every housewife was her own baker; for the word *pistor*, which we find in Roman authors before this period, signified, as Varro justly observes, a person who ground or pounded the grain in a mill or mortar to prepare it for baking. According to Athenæus, the Cappadocians were the most approved bakers; after them the Lydians; and then the Phœnicians. To the foreign bakers brought into Rome were added a number of freedmen, who were incorporated into a body, or, as they termed it, a college; from which neither they nor their children were ever allowed to withdraw. They held their effects in common, and could not dispose of any part of them. Every bakehouse had a *patronus* intrusted with the superintendence of it; and these patroni again elected one of their number every year, who had superintendence over all the rest, and the care of the college. Out of the body of the bakers one was every now and then admitted among the senators; and, to preserve honour and honesty in the college, they were expressly prohibited all alliance with comedians and gladiators. Every one had his own shop or bakehouse, and they were distributed into fourteen regions or wards of the city. They were excused from guardianships and other offices which might divert them from their employment. By British statutes bakers are declared not to be handicraftsmen. No man for using the mysteries or sciences of baking, brewing, surgery, or writing, shall be interpreted a handicraftsman. The bakers were a brotherhood in England before the year 1155, in the reign of King Henry II., although the white bakers were not incorporated till 1407, and the brown bakers not till 1621. The French had anciently a great baker, *grand panetier de France*, who had the superintendence of all the bakers of Paris.

BAKER, *Henry*, an ingenious and diligent naturalist, was born in Fleet Street, London, either near the end of the seventeenth, or very early in the beginning of the eighteenth century. His father's profession is not known, but his mother was in her time a midwife of great practice. He was brought up under an eminent bookseller, who preceded the elder Dodsley, to the business of a bookseller; in which, however, he appears not to have engaged at all after his apprenticeship, or if he did, it was soon relinquished by him; for although it was in his power to have drawn away many of his master's customers, he would not set up against him. Mr Baker being of a philosophical turn of mind, and having diligently attended to the methods which might be practicable and useful in the cure of stammering, especially in teaching deaf and dumb persons to speak, made this the employment of his life. In the prosecution of so valuable and difficult an undertaking he was very successful, and several of his pupils have borne testimony to the ability and good effect of his instructions. He married Sophia, youngest daughter of the famous Daniel Defoe, who brought him two sons, both of whom he survived. On the 29th of January 1740 Mr Baker was elected a fellow of the Society of Antiquaries, and on the 12th of March following the same honour was conferred upon him by the Royal Society. In 1744 Sir Godfrey Copley's gold medal was bestowed upon

Baker. him, for having, by his microscopical experiments on the crystallizations and configuration of saline particles, produced the most extraordinary discovery during that year. Having led a very useful and honourable life, he died at his apartments in the Strand on the 25th of November 1774, being then above seventy years of age. Several of Mr Baker's communications are printed in the *Philosophical Transactions;* and he was the means, by his extensive correspondence, of conveying to the society much useful intelligence. He was one of the earliest members of the Society for the Encouragement of Arts, Manufactures, and Commerce, and contributed in no small degree to its rise and establishment. His principal publications are, *The Microscope made Easy*, and *Employment for the Microscope*. The first of these was published in 1742 or 1743. The second edition of the other appeared in 1764. These treatises, especially the latter, contain the most curious and important of the observations and experiments which Mr Baker either laid before the Royal Society or published separately. His memory is perpetuated by the Bakerian Lecture of the Royal Society, for the foundation of which he left by will the sum of L.100.

BAKER, *Sir Richard*, author of the *Chronicle of the Kings of England*, was born at Sissingherst, in Kent, about the year 1568. After going through the usual course at Hart Hall, Oxford, he travelled abroad. Upon his return he took his degree as master of arts, and in 1603 received the honour of knighthood. In 1620 he was made high sheriff of Oxfordshire: but having engaged to pay some debts of his wife's family, he was reduced to poverty, and obliged to betake himself for shelter to the Fleet prison, where he died, February 18. 1645. During his confinement, he composed numerous works, historical, poetical, and miscellaneous. Amongst these are Meditations and Disquisitions on the Lord's Prayer; Meditations, &c., on several of the Psalms of David; Meditations and Prayers upon the Seven Days of the Week; *Cato Variegatus*, or Cato's Moral Distichs; *Theatrus Triumphans*, or *Theatrus Redivivus*, being a reply to Prynne's *Histriomastix*, &c. His principal work, the *Chronicle of the Kings of England*, long maintained its reputation among the less critical class of readers, but is now in little esteem. The author seems to have been sometimes more studious to please than to inform, and with that view to have sacrificed even chronology itself to method. In 1658, Edward Philips, nephew to Milton, published a third edition of this work, with the addition of the reign of Charles I. Sir Richard also translated several works from the French and Italian.

BAKER, *Thomas*, an eminent mathematician, was born at Ilton in Somersetshire about the year 1625, and entered at Magdalen Hall, Oxford, in 1640. He became vicar of Bishop's-Nymmet, in Devonshire, where he wrote *The Geometrical Key, or the Gate of Equations unlocked*, London, 1684. He died at Bishop's-Nymmet on the 5th of June 1690.

BAKER, *Thomas*, a very ingenious and learned antiquary, descended from an ancient family distinguished by its loyalty, was born at Crook in 1656. He was educated at the free school at Durham, and thence removed, in 1674, to St John's College, Cambridge, where he took his degree of A.M. in 1681, and afterwards was elected fellow. Lord Crew, bishop of Durham, collated him to the rectory of Long-Newton in his diocese, in 1687; and further intended to give him that of Sedgefield, with a golden prebend, had he not incurred his lordship's displeasure for refusing to read King James II.'s declaration for liberty of conscience. The bishop, who disgraced him for this refusal, and was excepted out of King William's pardon, took the oaths to that king, and kept his bishopric till his death. Baker resigned Long-Newton on the 1st of August 1690, refusing to take the oaths; and retired to St John's, in which he was protected till the 20th of January 1716–17, when he, with one-and-twenty others, was deprived of his fellowship. After the passing of the Registering Act in 1723, he was desired to register his annuity of L.40, which the last act required before it was amended and explained. Though this annuity, left him by his father for his fortune, with L.20 per annum out of his collieries by his elder brother, was now his whole subsistence, he could not be prevailed on to secure himself against the act. He retained a lively resentment of his deprivations; and wrote himself in all his books, as well as in those which he gave to the college library, *socius ejectus*, and in some *rector ejectus*. He continued to reside in the college as commoner-master till his death, which happened on the 2d of July 1740, in consequence of a paralytic stroke.

Baker || Bakewell.

Having been appointed one of the executors of his elder brother's will, by which a large sum was bequeathed to pious uses, he prevailed on the other two executors, who were his younger brother Francis and the Hon. Charles Montagu, to lay out L.1310 of the money upon an estate to be settled upon St John's College for six exhibitioners. He likewise gave to the college L.100 for the consideration of L.6 a-year, then only legal interest, during his life; and to the library several choice books, both printed and in manuscript, with medals and coins; besides what he left to it by his will viz. "all such books, printed and manuscript, as he had, and were wanting there." All that he ever published were, *Reflections on Learning, showing the Insufficiency thereof in its several particulars, in order to evince the usefulness and necessity of Revelation*, Lond. 1709–10; and the preface to Bishop Fisher's *Funeral Sermon for Margaret Countess of Richmond and Derby*, 1708; both without his name. His manuscript collections relative to the history and antiquities of the university of Cambridge, amounting to forty-nine volumes in folio and three in quarto, are divided between the British Museum and the public library at Cambridge: the former possesses twenty-three volumes, the latter sixteen in folio and three in quarto. Dr Knight styles him "the greatest master of the antiquities of this our university;" and Hearne says, "Optandum est ut sua quoque collectanea de antiquitatibus Cantabrigiensibus juris faciat publici Cl. Bakerus, quippe qui eruditione summa judicioque acri et subacto polleat." He had intended something like an *Athenæ Cantabrigienses*, on the plan of the *Athenæ Oxonienses*. The life of Baker has been written by Robert Martin, 8vo, 1784; and by Horace Walpole, in the quarto edition of his works.

BAKEWELL, ROBERT, a distinguished agriculturist and improver of live stock, was born at Dishley, in Leicestershire, in 1725 or 1726, and died there in October 1795. His attention was more particularly devoted to the improvement of the race of sheep known as the Dishley or New Leicestershire breed; in which he was so successful that some of his rams were let for the season at the extraordinary sum of four hundred guineas. The improvements he introduced in the breeding of live stock generally were such as to secure him a high rank among the benefactors of British husbandry.

BAKEWELL, a market-town in Derbyshire, on the River Wye, 152 miles from London. The church is a fine old structure, in the form of a cross. The inhabitants are supported by the working of the coal, lead, and zinc mines, and the stone and marble quarries in the neighbourhood. There is also a large cotton manufactory in the town. Bakewell is remarkable for its excellent trout-fishing, and for a chalybeate spring, frequented by invalids. It has a free school of very ancient date, a dispensary, and a literary and scientific institution, &c. Pop. in 1851, 2217.

BAKING.

Baking. BAKING properly means to heat anything in an oven or fire so as to harden it; and in this sense it is used when applied to the manufacture of bread, porcelain, pottery, bricks, &c. It is also used as synonymous with the words *cook* and *dress*, as when applied to baked meats, pies, &c. In the present article the baking of flour into bread will alone be treated of.

History of the art. Like most of the arts of primary importance, its origin precedes the period of history, and is involved in the obscurity of the early ages of the world. There is no evidence from Scripture that Abraham was acquainted with the method of making loaf-bread. Cakes and unleavened bread are repeatedly mentioned as made by him, but no notice is taken of loaf-bread. We are certain that it was known in the time of Moses, as in the Jewish law there is a prohibition against making use of it during the celebration of the passover. (Exodus, chap. xii. verse 15.) Egypt, both from the nature of the country and the early period of its civilization, seems very probably to have been the place where this art was first practised. The Chaldeans, however, put in a claim. They were civilized nearly as early as the Egyptians, and they were celebrated among the ancients for the excellence of their bread. The Greeks assure us that they were taught the art of making bread by the god Pan. This lively and superstitious people ascribed almost all the important arts of common life to their gods; or rather, perhaps, their gratitude induced them to deify the authors of these most useful inventions. Bakers first settled in Rome during the war with Perseus, king of Macedon. (Plinii *Hist. Nat.* xviii. 11.) It was then that the Romans became acquainted with the refinements of the Greeks, and that their capital became crowded with adventurers of all kinds, with artists and philosophers, from the prolific soil of Achaia. Before this period the Romans were often distinguished or reproached by the appellation of the *pulse-eating nation.*

Since the introduction of bakers into Rome. the art of making bread has always been practised in the south of Europe. But it made its way into the north very slowly; and even at present, in the northern countries of Europe and Asia, loaf-bread is seldom used except by the higher classes of inhabitants. In Sweden, for example, you see rolls frequently in the towns, but never loaves. Göttenburg is a town containing about 23,000 inhabitants. In the year 1812 it was crowded with merchants from all parts of Europe, being the great connecting link between Britain and the Continent. Towards the end of that year the captain of an English packet ordered a Göttenburg baker to bake for him a quantity of bread, amounting to L.1 sterling in value. The baker was confounded at so great an order, and refused to comply till the captain gave him security that he would carry off and pay for the loaves, declaring that he could never dispose of so great a quantity of bread in Göttenburg if it were left upon his hands. In the country part of Sweden no bread is made but rye-cakes, as hard nearly as flint, and which are only baked twice a year. About eighty years ago loaf-bread was almost as rare in the country places and villages of Scotland, *barley bannocks* and *oaten cakes* constituting the universal substitutes among almost all ranks. But the case is much otherwise now.

In many parts of England it is the custom for private families to bake their own bread. This is particularly the case in Kent, and in some parts of Lancashire. In the year 1804 the town of Manchester, with a population of 90,000 persons, did not contain a single public baker.

Unfermented Bread. Bread consists of two kinds, fermented and unfermented. Unfermented bread consists of the flour of various kinds of grains or pulse, formed by means of water into a thick paste or doughy mass, and then fired either in a regular oven, or a hot iron plate, or by being put into a hole heated by fuel of some kind, where it is covered over with the ashes till thoroughly cooked. When the firing is carried so far as to dry and harden this kind of unfermented bread, it receives the name of biscuit (from the French words meaning *twice fired*): when less thoroughly baked the bread forms a heavy rather solid loaf or cake, which receives the various names of cake, bannock, scone, damper, &c., and is the form of bread used most generally over the world. Baking.

Almost every kind of edible grain is used in baking unfermented bread. In the warmer regions of the globe, and in the torrid zone, maize and rice take the place of most other grains, and perhaps a larger portion of the human race feed on these two grains than on all the rest put together. In northern latitudes again, rye, barley, and oats are the chief grains used as human food. But in all the temperate zones wheat is the chief and most valuable of the grains. In various countries, but to a comparatively small extent, flour of pease, beans, lentils, millet, guinea corn or dhurra, &c., are used to form their unfermented bread.

Unfermented bread possesses this great advantage over fermented bread, that when well fired, and so dried as to have assumed the form of biscuit, it will keep unchanged for a very long period of time. Hence its value as ship stores, seeing that on board ship there is not the convenience for baking loaf-bread daily for such a large number of men.

Manufacture of Navy Biscuits. At the victualling departments of our navy yards, almost all the biscuits for ship stores are now manufactured with the aid of machinery. The application of machinery to this department gives immense advantages over the old system of baking biscuits by hand labour, in addition to doing the whole work much better, making superior biscuits, and saving fully two-thirds on wages alone. Thus it is calculated that at the baking establishments at Deptford, Gosport, and Plymouth. from seven to eight thousand tons of biscuits could be annually produced, at a saving of L.12,000 from the cost under the system of hand manufacture. Biscuits for the navy are manufactured only of the best wheaten flour, but experience has fully demonstrated that the health of the seamen is much better preserved by the flour having a certain admixture of bran in it, than when the whole bran is thoroughly removed. The following account of the manufacture of biscuits for the navy at the Royal Clarence Victualling Establishment at Weevil, near Portsmouth, from the *United Service Journal*, will be read with interest.

"It having been discovered that the flour supplied to government by contract, had in some instances been most shamefully adulterated, the corn is ground at mills comprised within the establishment, by which means the introduction of improper ingredients is prevented, and precisely the proportion of bran which is requisite in the composition of good sea biscuit is retained, and no more. The flour mill is furnished with ten pairs of stones, by which forty bushels of flour may be ground and dressed ready for baking in an hour. The baking establishment consists of 9 ovens, each 13 feet long by 11 feet wide, and 17½ inches in height. These are each heated by separate furnaces, so constructed that a blast of hot air and fire sweeps through them, and gives to the interior the requisite dose of heat in an incredible short space of time. The first operation in making the biscuits consists in mixing the flour, or rather meal and water; 13 gallons of water are first introduced into a trough, and then a sack of meal weighing 280 lb. When the whole has been poured in by a channel communicating with an upper room, a bell rings, and the trough is closed. An apparatus, consisting of two sets of what are called knives, each set ten in number, are then made to revolve

Baking. among the flour and water by means of machinery. This mixing operation lasts one minute and a half, during which time the double set of knives or stirrers makes twenty-six revolutions. The next process is to cast the lumps of dough under what are called the breaking rollers,—huge cylinders of iron, weighing 14 cwt. each, and moved horizontally by the machinery along stout tables. The dough is thus formed into large rude masses 6 feet long by 3 feet broad, and several inches thick. At this stage of the business the kneading is still very imperfect, and traces of dry flour may still be detected. These great masses of dough are now drawn out, and cut into a number of smaller masses about a foot and a half long by a foot wide, and again thrust under the rollers, which is repeated until the mixture is so complete that not the slightest trace of any inequality is discoverable in any part of the mass. It should have been stated that two workmen stand one at each side of the rollers, and as the dough is flattened out they fold it up, or double up one part upon another, so that the roller at its next passage squeezes these parts together, and forces them to mix. The dough is next cut into small portions, and being placed upon large flat boards, is, by the agency of machinery, conveyed from the centre to the extremity of the baking room. Here it is received by a workman who places it under what is called the sheet roller, but which for size, colour, and thickness, more nearly resembles a blanket. The kneading is thus complete, and the dough only requires to be cut into biscuits before it is committed to the oven. The cutting is effected by what is called the cutting-plate, consisting of a net-work of fifty-two sharp-edged hexagonal frames, each as large as a biscuit. This frame is moved slowly up and down by machinery, and the workman, watching his opportunity, slides under it the above described blanket of dough, which is about the size of a leaf of a dining-table; and the cutting frame, in its descent, indents the sheet, but does not actually cut it through, but leaves sufficient substance to enable the workman at the mouth of the oven to jerk the whole mass of biscuits unbroken into it. The dough is prevented sticking to the cutting-frame by the following ingenious device: between each of the cutter-frames is a small flat open frame, moveable up and down, and loaded with an iron ball weighing several ounces. When the great frame comes down upon the dough, and cuts out fifty-two biscuits, each of these minor frames yields to the pressure and is raised up; but as soon as the great frame rises, the weight of the balls, acting on the little frames, thrusts the whole blanket off and allows the workmen to pull it out." Each biscuit is stamped with the government mark, and the number of the oven, as well as punctured with holes, by the same movement which cuts out the piece of dough. One quarter of an hour is sufficient to bake the biscuit; they are then withdrawn from the oven, broken asunder by the hand, and placed for three days in a drying-room heated to 85° or 90°. Dr Ure mentions that it was found, on experiment at the above-mentioned baking establishment, that in 116 days, during 68 of which the work was continued for only 7½ hours; and during 48 days for only 5¾ hours each day, in all 769 working hours, 12,307 cwt., or 1,378,400 lb. of biscuits were produced from the nine ovens. The wages of the men employed amounted to L.273, 10s. 9½d.; whereas, if the same quantity had been made by hand labour, the wages alone would have amounted to L.933, 9s. 10d.; showing a saving during that time, in the matter of wages alone, to the extent of L.659, 7s. 0½d.

Fermented Bread. Fermented or loaf bread differs from unfermented bread in being light and spongy, in being full of small cavities, in having a more agreeable taste, and in being more easily chewed and digested. Fermented bread can only be made from flour which contains the substance called gluten as one of its ingredients, and wheat is the only grain which contains it in sufficient abundance to form a light and spongy bread. Rye, which next to wheat contains the greatest quantity of gluten, is also capable of being formed into a fermented bread, but very inferior in lightness and sponginess to that made from wheat flour. Gluten is the viscid substance which is left in the mouth when wheat is long chewed, and may more easily be procured by forming flour into dough with water, putting this into a muslin bag, and washing and kneading it till all the starch is washed out: the glutinous matter left in the bag is the impure gluten. The finer the wheat the larger is the proportion of this matter, and consequently the better fitted for making loaf-bread. It is this viscid substance which gives wheaten flour, when made into dough, that superior tenacity which enables it to be raised by fermentation. Wheat, besides gluten, contains starch, sugar, gum, also small quantities of albumen, caseine, and fatty matter or oil. The following table shows the relative quantities of the constituent parts of wheat flours, as ascertained by Vauquelin in 100 parts of flour. Baking.

Species of Wheat Flour.	Water.	Gluten.	Starch.	Sugar.	Gum.	Bran.
Raw wheat of Odessa flour, *Vauquelin*.....	12·0	14·55	56·50	8·48	4·00	2·3
Soft wheat of Odessa flour, *V*.....	10·0	12·00	62·00	7·56	5·80	1·2
French wheat flour, *V*....	10·0	10·96	71·49	4·72	3·32	...
Wheat of Paris hospitals (second quality..	8·0	10·30	71·20	4·80	3·60	...

Sir Humphry Davy and others have estimated the quantity of gluten in wheat flour so high as from 19 to 24 per cent. But this probably resulted from their not drying the gluten thoroughly, or freeing it sufficiently from foreign ingredients. Professor Johnston, from numerous experiments carefully conducted in his laboratory, states, "we may safely, I think, conclude from these, that English flour seldom contains more than 10 per cent. of dry gluten;" and he gives a long table of the results actually obtained in proof of his statement. (*Agric. Chemistry*, p. 871.)

When wheat is ground it is sifted so as to separate the bran, which consists of the coarse outer skin of the grain, and the parts of the grain which are more or less imperfectly or coarsely ground. Professor Johnston states, that taking as an example three lots of good wheat ground at Mr Robson's mills, Durham, the yield of the different products was respectively, per 100 parts of the wheat:—

	1st Lot.	2d Lot.	3d Lot.
Fine flour	74·2	75·1	77·9
Boxings, or coarser flour.....	9·0	8·3	6·1
Sharps or pollard.....	5·8	6·6	5·6
Bran	7·8	7·0	6·9
Waste	3·2	3·0	3·5
	100·0	100·0	100·0

From Mr John R. Tait, mill-owner and baker in Edinburgh, we have received the following as the average yield of good wheat flour, the whole being copied from one of his actual mill receipts for May 1853. Thirty-two Scotch bolls, or 16 quarters of wheat, at the average weight of 63¾ lb. per bushel—weighing in all 578 st. 11 lb.—yielded of

	St.	Lb.
Fine flour	414	0
Odd and second flour	23	13
Parings (sharps and pollard)	36	12
Bran and shellings	92	0
Waste	11	0
Total,	578	11

According to the purpose for which the flour is required, the second flour is sometimes not separated; in which case the 578 st. 11 lb. of wheat would yield 437 st. 13 lb. of flour, the other ingredients remaining the same; and Mr Tait's mill receipts are so uniform for a series of years, that the above may be taken as the average production of

Baking.

flour from the best wheat sold in the Edinburgh and Lithgow markets.

Use of Leaven.

When wheat flour is made into a dough by means of water, and is kept in a warm place, a spontaneous fermentation occurs among its particles, causing it to swell up. This, for distinction's sake, has been called the *panary* fermentation. This fermentation goes on at the expense of the sugar and starch in the flour, a portion of the carbon and oxygen of these principles combining in the proportions to form carbonic acid gas. As the escape of this gas is prevented by the tough or viscid gluten in the dough, the whole mass is swelled by the formation of numerous vesicular cavities, which are filled with this gas, and which are very apparent in the bread when baked. Dough, when thus naturally fermented, requires not only much time, but possesses the additional disadvantage of having contracted an acidity and a putrescent flavour, both of which seriously injure the quality of the bread. This used to be got the better of by using this self-fermented mass as leaven only, adding a comparatively small piece of it to a large mass of fresh-made dough. This leaven rapidly excited the fermentive process in the whole of the new mass, and the whole mass was then said to be leavened.

Yeast.

This was, however, a clumsy way of exciting the panary fermentation in large masses of dough; and it was soon discovered that the addition of yeast or barm, *i. e.* the frothy scum which rises to the surface of beer when it is undergoing fermentation, was a much more speedy mode of accomplishing the same end. At first all the yeast used was obtained from the brewers; but now, in almost every large town, yeast or barm breweries exist, where a wort from pure malt is fermented alone, for the sole purpose of supplying the bakers with yeast for baking.

Pliny informs us that yeast in his time was employed in Spain and Gaul as a *ferment* of bread. *Galliæ et Hispaniæ frumento in potum resoluto, quibus diximus generibus, spuma ita concreta pro fermento utuntur. Qua de causa levior illis quam cæteris panis est.* (*Hist. Nat.* lib. xviii. c. 7.) From this passage we see that the Romans employed leaven to raise their bread, but that they were sensible of the superiority of yeast. Leaven, however, made its way both into France and Spain, and was universally employed in the manufacture of bread till towards the end of the seventeenth century, when the bakers of Paris began to import yeast from Flanders, and to employ it pretty generally as a substitute for leaven. We have here a striking instance of the blindness and obstinacy of the learned and the powerful, and the readiness with which they are disposed to arm themselves against all alterations and improvements. The bread by this substitution was manifestly improved, both in appearance and in flavour. This variation excited attention; the cause was discovered; the faculty of medicine in Paris declared it prejudicial to the health; the French government interfered; and the bakers were prohibited, under a severe penalty, from employing yeast in the manufacture of bread.

But it is in vain for governments, colleges, and universities, to oppose themselves to those improvements which take place in the arts and manufactures essential to civilized society. The ingenuity and perseverance of self-interest is proof against prohibitions, and contrives to elude the vigilance of the most active government. The laws of Queen Elizabeth, however tyrannical and absurd, did not prevent the introduction of indigo as a dye-stuff into England. Neither did the authority of Louis the Fourteenth, nor the decision of the physicians, deter the Parisian bakers from persisting in their improved mode of making bread. The yeast in Flanders was put into sacks; the moisture was allowed to drop out; and in this comparatively dry state it was carried to the capital of France.

Baking.

The superiority of yeast bread became gradually visible to all; the decisions of the medical faculty were forgotten; and the prohibition laws were allowed tacitly to sink into oblivion. The new mode of baking by degrees extended itself to other countries, and is now, we believe, practised everywhere. In warm climates, where the yeast of beer cannot be had, other substitutes are employed, which answer the same purpose.

Nature of panary fermentation.

It was formerly much disputed whether the panary fermentation was the same as, or different from, the vinous. But the researches of Dr Colquhoun, Mr Graham, and others, have settled the question by showing that it is neither more nor less than true vinous fermentation; and the fact may be easily shown by inclosing the loaf when baking in a close oven, and condensing the vapour which escapes from it, when alcohol is obtained. If, however, the dough be allowed to sour before being subjected to the heat, no alcohol is obtained, because the next stage of the vinous fermentation has been gone through, namely, the acetous, when all the alcohol assumes the form of the acetic or lactic acids. Following out these researches, it was found that the fermentation was mainly dependent on the saccharine matter in the wheat, aided by the conversion of a portion of the starch into sugar, as happens in the well-known process of malting.

Mixing of ingredients

When the baker prepares his dough for a batch, according to circumstances he either mixes the whole ingredients together at once—called setting the whole sponge,—or else he only mixes a quarter of the ingredients at one time,—called setting quarter-sponge. The quantity of ingredients used in setting a sponge varies according to the sale of the bread; but for a bag of good wheat, weighing 280 lb., about 15 gallons of water, of about the temperature of 90°, 5 lb. of salt, and 1½ pint of yeast are employed. In Edinburgh it has been found, by numerous experiments conducted on the large scale by the best bakers, whose bread is unequalled for quality, that the best bread is produced by setting the whole sponge at once. In London, and most towns where much of the bread sold is very inferior, the custom is to mix at first only a fourth of the flour which is intended to be employed, adding only half a pint of yeast and the requisite proportion of salt. This is called setting quarter-sponge. In this case some dry flour is thrown over the top of the mass, and cloths are thrown over the barrel in which the mixture is made. It is then left for three hours. By this time active fermentation has been excited in the whole mass, which has swollen up, burst, and collapsed two or three times. An additional quarter of flour, and its proportion of salt and water, are then added to the mass, the whole intimately mixed and left for about five hours. This is termed setting half-sponge. After this period the other half of the flour, with its relative proportions of salt and water, are added, the whole mixed intimately for about an hour; and this is termed setting whole sponge; after which the dough is laid in the baking-trough and covered up for about four hours.

Setting the whole sponge the best method.

As above mentioned, the best Edinburgh bakers greatly prefer setting the whole sponge at once; and the knowledge of the chemical nature of the changes which the flour undergoes during the fermentation, quite bears out the practical conclusion that such should not only produce better bread than by setting quarter-sponge, but also that the produce of loaves from the bag of flour should be greater. By the plan of setting quarter-sponge, a portion of the flour is kept in a state of fermentation for a much longer period than by the whole-sponge process; the natural consequence of which is, that a much larger quantity of the sugar and starch in the flour is decomposed, and the whole mass has a greater tendency to pass into the next stage of fermentation—the acetous fermentation. The bread prepared by the quarter-sponge

process is therefore not only diminished in quantity, but also sooner gets sour than when the whole sponge is set at once; and instead of a bag of flour yielding from 96 to 100 loaves, each 4 lb. in weight, which it does by the whole-sponge process, the number of loaves rarely if ever exceeds 94. As a general rule it takes 3 lb. of good flour to make a well-fired loaf weighing 4 lb.

When the dough is sufficiently fermented it is well kneaded, and is then weighed out into masses weighing 4½ lb. each. During the firing this half-pound is nearly dissipated, so that when the loaf comes from the oven it weighs somewhat more than 4 lb., and when well and properly fired will not fall below that weight for 24 or 36 hours. Many London and second-rate bakers, in order to make more loaves out of a bag of flour, and yet keep up the weight of the loaf, under-fire their bread, and when it is removed from the oven, place it in a close place, and cover it over with thick cloths till it cools. This greatly deteriorates the bread, rendering it heavy, more indigestible, and prone to turn acid and mouldy. The first-rate Edinburgh bakers, who fire their bread so much more thoroughly, expose the loaves freely to the air when removed from the oven, by placing them in open shelves, and do all in their power to prevent the vapour rising from the warm bread condensing on the loaves themselves. It seems to be mainly attention to these points, viz. setting at once the whole sponge, thorough firing, and free exposure of the bread to the air during its cooling, that the great superiority of the Edinburgh bread is to be attributed. But it may be remarked that no subsequent attention will make up for the want of good flour.

Importance of thorough firing and exposure to air.

In London, where so much bad bread is made, and inferior flour is used, it is not unusual to add alum, in proportions varying from one ounce to six or eight ounces to the bag of flour: the more inferior the flour, the larger is the quantity of alum used. This addition is supposed to render the bread firmer and whiter, and it certainly appears to have such an effect on the inferior flours; and, as in London bread is valued according to its whiteness, the Londoners are content to eat an inferior and not so wholesome bread in order to please the eye. Potatoes and several other articles are used to adulterate the flour from which bread is prepared, but it is unnecessary to particularize these, as every addition to wheaten flour only deteriorates the bread baked from it. See ADULTERATION, and FOOD.

Use of alum.

An important desideratum has long been felt, viz. an easy mode of ascertaining the relative goodness of bread. The comfort and health of so many are dependent on the purity and goodness of the bread they use, that it is astonishing so few attempts have been made to find a test easy of application for this purpose. One of the most intelligent of the bakers in Edinburgh mentioned to us one test he has been in the habit of using for twenty years past with uniform success. Well-fired bread, made of good and pure wheat flour, is dry, light, and spongy. Bread made of inferior flour, or to which has been added rye, barley, potatoes, potato starch, alum, &c., or bread under-fired, or sweated, or acid, is heavier, damper, and less spongy. The test is: cut from the two loaves pieces of equal size, and put them in saucers having each the same quantity of water, the best bread will invariably absorb the most water. The same may be more accurately done by cutting the pieces of bread of equal weight, placing each in water till thoroughly saturated, and weighing each piece again. Invariably the best bread will be found to have absorbed the largest quantity of water and to weigh the heaviest.

Testing of bread.

Baking || Baku.

The varieties of bread baked in this country are endless, and it would only be waste of space to mention them here. It may merely be mentioned, that when the bread is desired to be especially light and porous the dough is fired in deep iron pans, which, by preventing the escape of carbonic acid gas from the sides of the loaf, causes the whole loaf to swell up more, and produces a greater amount of sponginess. Bread thus baked is termed *pan* or *pan-soled* bread.

With many invalids even the best fermented or leavened bread disagrees, and it has been the aim of many bakers to produce a light and spongy bread by the disengagement of carbonic acid gas or other vapour in the mass of dough, during the firing, without the use of yeast or leaven. For this purpose carbonate of ammonia has been and is extensively used; and, as this substance is totally volatilized by the heat of the oven, it imparts neither smell nor taste to the bread, yet, by assuming the gaseous form in the dough, causes it to swell out, thus rendering it light and spongy, and consequently easily digestible. With the same end in view muriatic acid (spirit of salt) and carbonate of soda, in the proper proportions for forming table salt, have been used with perfect success. Others again have used with the same view carbonate of soda and tartaric acid, in the proper proportions to neutralize each other; and it is by one of these three processes that most of the light spongy unfermented bread now sold is prepared. Whenever acid of any kind is used for this end, it ought always to be used in the exact proportion to neutralize the soda used; if the soda be in excess, the bread assumes a yellowish discoloured hue; if the acid be in excess, the bread is unpleasant to eat. We have often baked very pleasant bread by using 600 grains carbonate of soda and six drachms muriatic acid to 8 lb. of flour. Some however use a half more of the soda and acid to the same quantity of flour. When from oversight, or from the panary fermentation having gone on too rapidly, the dough has become sour, the acidity may be checked, and the bread rendered wholesome, by the addition of a small quantity of carbonate of soda or of magnesia. (J. S—K.)

Varieties of unleavened bread.

BAKU, or BADKU, a town, with an adjoining district of the same name, in the Russian province of Daghestan. Badku is the most spacious and convenient port in the Caspian. It stands in the peninsula of Apsheron, in Long. 49. 40. E. Lat. 40. 22. N. It is a place of considerable trade, and is defended by a double wall and ditch, constructed during the reign of Peter the Great. The town, which is situated on a declivity, is of an obtuse-triangular form, and was a celebrated resort of the ancient worshippers of fire. Before the conquest of the Saracens it was annually visited by thousands of pilgrims, and is still visited by a few Persian fire-worshippers. In the adjacent district a great quantity of excellent cotton is produced, which is exported from Badku; together with fruit, opium, rice, silk, wine, rock-salt, and naphtha. Cloths, dye-stuffs, iron, linen, and silk stuffs, are imported from Astracan, with which place its principal trade is carried on. In the plain nine miles north of the city, enormous quantities of naphtha are produced. It is drawn from wells, some of which yield from 1000 to 1500 lb. in a day; and the district, in dry weather, has often afforded as much as 5600 lb. in one day. The naphtha consists of two kinds, the impure or black, containing petroleum, and the pale yellow or white, which is pure naphtha. The quantity annually obtained in the district amounts to 240,000 Russian poods, or 9,600,000 lb. of the first sort, and 900 poods, or 36,000 lb. of the latter. The fundamental rock of this district appears to be a secondary limestone, on which is imposed a bed of white clay; then two strata of bituminous shale separated by a bed of sand; next a stratum of fossiliferous sandstone, covered by a bed of clay. The naphtha oozes through the fissures of the white clay, and probably is thus distilled by subterranean heat. These wells contain inexhaustible springs of oil; and they are no sooner emptied than the oil begins to flow, and continues until it has attained its former level. It is used by the natives for lamp-oil, and emits a clear light, with much smoke and a disagreeable odour. All around the town the

Bala ‖ Balaam.

country is deeply impregnated with inflammable matter, both above and below the surface. About 15 miles to the N.E. is a fire temple of the Guebres; a remarkable spot, something less than a mile in circumference, from the centre of which a bluish flame is seen to arise. Here are some small houses; and the inhabitants, when they wish to smother the flame, cover the space inclosed with walls by a thick loam of earth. When an incision is made in the floor, the flame arises; and when it is no longer wanted for culinary or other purposes, it is again suppressed by closing the aperture. The whole country around Badku has at times the appearance of being enveloped in flames. It often appears as if fire rolled down the mountains in large masses with great velocity; and at night a bright blue light is observed to cover the whole western range of hills. This fire does not consume, or emit any sensible warmth.

The jurisdiction of Baku extends over thirty-two villages. It was ceded to Russia in 1723, and restored to Persia in 1735. After remaining for some years under the dominion of Persia, in 1801 it was taken possession of by the Russians, by whom it is still retained. The district, including the town, contains, according to Klaproth, 19,000 inhabitants.

BALA, a market-town of Wales, county of Merioneth, and hundred of Penllyn, at the northern extremity of a small lake, 17 miles N.E. of Dolgelly. It consists principally of one wide street. Its manufactures are flannels, stockings, and gloves. The lake of Bala is four miles long and about half a mile broad. It is very deep and clear, and abounds with pike, perch, trout, eels, and the *gwyniad*, or *coregonus lavaretus*. The beds of limestone in the slate of this district, from their fossil contents, belong to the upper and lower series of silurian rocks.

BALAAM, a prophet and diviner of the city of Pethor on the Euphrates, whose practices with Balak, king of the Moabites, are recorded in the Book of Numbers, chap. xxii. In 2 Peter ii. 15, Balaam is called the son of Bosor, which Gesenius attributes to an early corruption of the text, but Dr Lightfoot considers it to be a Chaldaism, and infers from the apostle's use of it, that he was then resident at Babylon.

Of the numerous paradoxes which we find in this remarkable person, not the least striking is, that with the practice of an art expressly forbidden to the Israelites, he united the knowledge and worship of Jehovah, and was in the habit of receiving intimations of his will. The sacred narrative gives us no reason to suppose that he had any previous knowledge of the Israelites. In the absence of more copious and precise information, we may reasonably conjecture that Jacob's residence for twenty years in Mesopotamia contributed to maintain some just ideas of religion, though mingled with much superstition. To this source, and the existing remains of patriarchal religion, Balaam was probably indebted for that truth which he unhappily "held in unrighteousness."

On the narrative contained in Numb. xxii. 22–35 a difference of opinion has long existed, even among those who fully admit its authenticity. The advocates for a literal interpretation urge, that in a historical narrative it would be unnatural to regard any of the occurrences as taking place in vision, unless expressly so stated; that it would be difficult to determine where the vision begins, and where it ends; that Jehovah's "opening the mouth of the ass" must have been an external act; and, finally, that Peter's language is decidedly in favour of the literal sense. "The dumb ass, speaking with a man's voice, reproved the madness of the prophet" (2 Peter ii. 16). Those who conceive that the whole scene occurred in vision to Balaam (among whom are Maimonides, Leibnitz, and Hengstenberg), insist upon the fact that dreams and visions were the ordinary methods by which God made himself known to the prophets (Numb. xii. 6); they remark that Balaam speaks of himself as the man who had his eyes shut, and who, on falling down in prophetic ecstasy, had his "eyes opened;" that he expressed no surprise on hearing the ass speak; and that neither his servants nor the Moabitish princes who accompanied him appear to have been cognizant of any supernatural appearance. Gregory of Nyssa supposes that the ass did not utter any word articulately; but that having brayed as usual, the diviner, whose practice it had been to draw presages from the cries of beasts and singing of birds, comprehended easily the ass's meaning by its noise; and that Moses designed to ridicule the superstitious art of augurs and soothsayers, as if the ass had really spoken in words articulate.

Baladan ‖ Balance.

BALADAN, the Scripture name for a king of Babylon, called by profane authors *Belesus* or *Belesis*, *Nabonassar* or *Nanybrus*. See BELESIS.

BALÆNA, the common Greenland whale. See MAMMALIA.

BALAGHAUT DISTRICTS. This country, which is in the south of India, comprehends a large proportion of the tableland supported like a terrace by the stupendous mountain ranges of the Eastern and Western Ghauts. It extends from the Toombuddra and Krishna rivers on the north, to the southern extremity of Mysore, and is named Balaghaut or "above the Ghauts," in contradistinction to Payenghaut or "below the Ghauts." This tract of country comprehends, in addition to the native state of Mysore, the three British districts of Ballary, Cuddapah, and Kurnoul, the first two having been ceded by the Nizam in 1800, in commutation of subsidy, and the last taken from the nawaub of that district in 1841, in consequence of a breach of allegiance to the paramount power. The area of the Balaghaut, excluding the Mysore, is 28,669 square miles, and its population 2,954,710. Sugar, grain, and cotton, form the staple produce

In ancient times these provinces formed part of the Hindu kingdom of Bijyanagur; and many of the modern Polygars claim their descent from the officers, and some from the royal family of that kingdom. On the fall of the Mogul government, the Balaghaut was broken into several independent states. It was conquered by Hyder Ali between the years 1766 and 1780. Upon the dismemberment of Tippoo's dominions in 1800, the dependency of Kurnoul continued in the possession of its nawaub. Of the residue of the Balaghaut, a portion was assigned to the rajah of Mysore, the representative of a family dispossessed by Hyder Ali, but rescued by the British to participate in the results of their success over that usurper's son. That which remained was divided between the British and the Nizam. The dependency of Kurnoul and the portion of territory allotted to the Nizam, are now, as above stated, annexed to the British empire; the territory of Mysore, though still nominally constituting a native state, was some time since, in consequence of the misconduct of its affairs, transferred to the direct management and control of the British government. (E. T.)

BALAGUER (*Bargusia* of the Romans), a *partido* and city of the province of Lerida, in Spain. The city is situated on the right bank of the River Segra, in a fruitful district, and is defended by a citadel. Pop. 4642, chiefly occupied in the pursuits of agriculture. Long. 1. 24. E. Lat. 41. 43. N.

BALAMBANGAN, an island in the Eastern Seas, between Magindanao and Borneo. The East India Company formerly had a settlement here, but it is now abandoned. Long. 117. 5. E. Lat. 7. 15. N.

BALANCE, a machine for ascertaining the weight of substances. There are several kinds of balances, as the common balance or scales, the steelyard, the Danish or Swedish balance, the Chinese balance, the hydrostatic balance, &c. The same name is also given to certain kinds of apparatus for measuring or comparing the intensities of very small forces, as the balance of torsion, the electric balance, &c.

The common balance, which is of the most extensive use in the affairs of life, as well as in the arts and experi-

Balance. mental physics, consists of a beam, AB (fig. 1, Plate CIII.), supported in the middle by a fulcrum or prop C, round which it turns freely, and having a scale or dish attached to each of its extremities A, B, one of which holds the weight, and the other the substance to be weighed. The balance, therefore, in reference to the mechanical powers, is a lever of the first kind; that is to say, having the fulcrum placed between the power and the weight to be raised; hence its theory is easily deduced from the statical properties of the lever. Let P represent the weight in the scale D, and Q that in E; then (supposing AB an inflexible straight line without weight), when AB becomes stable in the horizontal position, or when P *balances* Q, the condition of equilibrium is expressed by the equation

$$P \times AC = Q \times BC.$$

In order, therefore, that the two bodies P and Q may have precisely the same weight, or both exert the same force in turning the beam about its axis of motion, it is indispensable that the two points of suspension A and B be exactly equidistant from the fulcrum C.

When the two arms of the balance are not exactly of the same length, it is obvious that the two weights P and Q, which, in the case of equilibrium, are reciprocally as CA and CB, must also be unequal, in order that the foregoing equation may still be true. If, for example, AC is longer than CB, then a less weight in D will balance a greater in E; and it is on this principle that false balances are constructed. The fraud, however, may be easily detected by transferring the weights P and Q to the opposite scales; for then the less weight P being attached to the shorter arm CB, the product P × CB will be smaller than Q × CA, and the equilibrium consequently destroyed.

It may be remarked, that the true weight of a body may easily be found by means of a false balance of this kind. It is only necessary to weigh the body first in the one scale and then in the other, and the true weight will be a mean proportional between the two weights thus indicated. To demonstrate this property, let w be the true weight of the body in grains, and suppose that when placed in the scale E it balances p grains in D, and that when transferred to D it balances q grains in E, and makes $m = AC$, $n = BC$; by the statical property of the lever we have the two equations,

$$mp = nw,\ nq = mw;$$

$$\text{whence } \frac{m}{n} = \frac{w}{p},\ \frac{m}{n} = \frac{q}{w};$$

$$\text{therefore } \frac{w}{p} = \frac{q}{w} \text{ and } w = \sqrt{pq};$$

so that w is a mean proportional between p and q, and is consequently found by multiplying those numbers together, and extracting the square root of their product.

In what precedes, the beam has been regarded as an inflexible rod devoid of weight; but in order to investigate fully the properties of the instrument, and the conditions that must be fulfilled in order to render it practically useful, it is necessary to have regard to the weight of the beam, and the position of its centre of gravity in respect of the axis of motion. The great requisites of a good balance are sensibility and stability; that is to say, it ought to be such that a very small weight added to either scale disturbs the equilibrium, and causes the beam to deviate sensibly from the horizontal position; and also such, that when the equilibrium has been disturbed, it may return quickly to a state of rest. In order to discover the construction best adapted to confer these two properties, it is convenient to regard the beam as a bent lever. Let G (fig. 2) be the centre of gravity of the beam, O the middle point of the straight line joining the points of suspension A and B, H′H a horizontal straight line drawn through C, and GD, OE, BH, AH′, perpendiculars to H′H. Balance. Make

W = weight of beam,
L = weight of scales with their load,
P = the preponderating weight,
φ = COE = BOK = angle of inclination.

The condition of equilibrium is now

$$L.CE + W.CD = P.CH;$$

whence, since CH = EH − EC = OK − EC,

$$L.OC \sin.\varphi + W.GC \sin.\varphi = P.OB \cos.\varphi - P.OC \sin.\varphi;$$

$$\text{therefore, } \sin.\varphi\,[(L+P).OC + W.GC] = P.OB \cos.\varphi;$$

$$\text{and } \tan.\varphi = \frac{\sin.\varphi}{\cos.\varphi} = \frac{P.OB}{(L+P).OC + W.GC}.$$

From this equation it appears that, for any given value of P, the tangent of the angle of inclination, which measures the sensibility of the balance, is directly as the length of the beam, inversely as the weights of the beam and load, and also inversely as the distances of G and O from the axis. The sensibility is therefore greatest when the quantity (L + P) . OC + W . CG is the least possible. On the other hand, when P = 0, the stability, or the force acting to restore the beam to the horizontal position, is sin. φ [L . OC + W . CG], which will be diminished by diminishing the value of L . OC + W . CG.

In what precedes we have supposed the points G and O both to fall below the centre of the motion C; but the balance may be constructed so that one or both of these points shall coincide with C, or fall above it. Suppose, in the first place, the arms to be bent upwards, so that O falls above the fulcrum, while G remains below it. In this case the measure of stability is sin. φ (W.CG − L.OC), whence it appears that a balance of this sort can only be used for small weights; for if the load is increased till L.OC becomes equal to W.CG, the balance has no restoring power, and is indifferent to any position. If L.OC exceeds W.CG, it would entirely upset by the slightest deviation from the horizontal position.

Suppose next that the centre of gravity G falls above the fulcrum, O remaining below it. The measure of stability now becomes sin. φ (L.OC − W.CG), and consequently the balance is only useful for heavy weights; for as L.OC is diminished, the stability is lessened, and when L.OC is equal to or less than W.CG, the balance is useless. Hence it appears that when either of the points G, O, falls above C, the balance can only be employed in particular cases.

Let the point G coincide with C, and O fall below it. In this case CG vanishes, and the measure of stability becomes sin. φ L.OC, which, for any given value of φ, increases with the load, or the weight of the substance to be weighed. A balance of this sort would be unfit for weighing small bodies on account of its want of stability, though it might be used in the estimation of great weights.

Lastly, let O coincide with C, while G falls below the axis. The three points of action A, C, B, are now arranged in a straight line, and the measure of stability is sin. φ W . CG, which is constant for a given value of φ. The restoring force is therefore independent of the load in the scales, so that a balance of this sort can be employed in all cases, whether the weights are great or small; and as it is easy, diminishing W and CG, to give it any required degree of sensibility, it is this form that ought to be adopted in every case where great precision and accuracy are necessary.

Another reason for this disposition of the three points of action in a straight line is, that unless C is in the same straight line with A and B, an equilibrium will subsist between two unequal weights when AB is not exactly horizontal. In fact, since the weights P, Q, suspended from A and B, act in the direction perpendicular to H′H, the mo-

Balance. ments of these weights, or their energies in turning the beam round its axis, are respectively P × CH′, and Q × CH; therefore, when BCH is a greater angle than ACH′, and the line CH consequently less than CH′, a smaller weight at A will balance a greater at B, and the beam remain at rest though loaded with unequal weights. It is hence important, in all accurate weighing, to make certain that when the equilibrium takes place, the line AB is exactly horizontal.

Having determined from theory the conditions that ought to be observed in the construction of the balance, we shall now proceed to give a brief description of the instrument as it is constructed for assaying or other delicate purposes. In the first place, the beam ought to be as light as possible, consistently with its perfect inflexibility; for it is evident that the friction of the axis will be increased with its weight, and the sensibility proportionally diminished. To combine the qualities of lightness and inflexibility, it is found most advantageous to form the arms of the balance of two hollow cones of brass, very thin, but strengthened and inflexible by means of circular rings driven into them at proper intervals. In order to diminish as much as possible the extent of the surfaces in contact, the axis is formed of two sharp edges of tempered steel, lying in the same straight line, and supported on two planes of steel, agate, or crystal, finely polished, and placed with the greatest precision, in the same horizontal plane. In a balance made by the celebrated Troughton, the sharp edges are ground on the lower side of a cylinder of steel, which crosses the beam in the middle, and they extend over the agate planes about $\frac{1}{20}$th of an inch. The angle of the edges is about 30°. The suspension at the extremities of the beam ought also to be made by sharp edges, crossing each other at right angles; and in order to obviate any risk of displacement, the edges may be concave, those formed in the beam being sharp upwards, and the others, to which the scales are attached, being sharp downwards. The horizontality of the beam is usually indicated by a slender pointed rod called the *tongue* of the balance, rising perpendicularly above the beam, and passing through the centres of gravity and motion. A divided ivory scale, placed contiguous to it, shows deviations of the tongue from the perpendicular, and renders sensible the slightest motion of the beam. In some balances the tongue is placed below the beam, pointing downwards, in order to diminish the volume of instrument. But the preferable method is to bring the arms themselves to terminate in sharp points, and place a divided scale behind each. By this means the tongue is rendered unnecessary, and any flexure of the beam immediately becomes evident. Care must be taken that the zeros of the two scales be placed exactly in the same level. The points of suspension at the extremities of the arms ought to be adjustable both horizontally and vertically; horizontally, for the purpose of giving the two arms exactly the same length; and vertically, in order to bring the three points of action into a straight line. A nut or bob, formed of some heavy substance, placed near the middle of the beam (in the interior of the cylinder if it be hollow), and capable of being raised or lowered by a screw, serves to increase or diminish the distance of the centre of gravity of the beam from the axis of motion, and consequently to accelerate or retard the oscillations at pleasure. Two supporters, the upper ends of which are formed into angles, are placed under the beam. These, being raised by means of a screw, lift the beam from the supporting planes, and relieve the sharp edges when the balance is not in use. If the arms of the balance are hollow, this object may be accomplished with less risk by placing the supporters under the extremities of the cross steel bar on which the sharp edges are formed. Props should also be placed under the scales while Balance. loading or unloading them; and care taken to confine the oscillations within narrow limits, or prevent the beam from deviating much from the horizontal position, by which the points of action might be endangered. The sensibility, as we have seen, increases with the length of the beam; but the liability to flexure also increases in the same proportion: and the arms of a balance, such as has been described, cannot, perhaps, safely exceed nine or ten inches. When great delicacy is required, the apparatus must be protected from the disturbing influences of currents of air, by being inclosed within a glass case, having doors at the ends for the convenience of loading and unloading the scales.

Fig. 3, Plate CIII. represents a balance by Fortin, a celebrated mechanician of Paris. The beam is made of tempered steel, and the arms slightly bent, so that all the parts of action may be situated in the same plane, and the centre of gravity fall a little below the axis of motion, which is here under the beam. The planes of support are of steel, and highly polished. The suspension at the extremities of the arms is represented by fig. 4.

With a balance of great sensibility, weighing is not only a delicate, but also tedious operation. When the adjustments are all perfect, and the beam nearly poised, the oscillations should be extremely slow and regular, and extend to equal distances on each side of the zero of the scale. In fact, it is by the equality of the excursions of the index from zero that the horizontality of the beam must be inferred; for a very long time would elapse before the oscillations entirely cease. The sensibility of a balance constructed with the requisite care, according to the principles above explained, is very great. Those of Fortin of Paris have been found to oscillate by the addition of a single milligramme, when loaded with a weight of 1000 grammes in each scale; so that the weight is indicated to the millionth part. A balance constructed by the late Mr Ramsden, for the Royal Society of London, is said to vibrate with the seven-millionth part of its load. In general, however, no such exactness can be hoped for; and even when the greatest precautions are taken, and the most delicate instruments employed, it would seldom be safe to vouch for the truth of any figure carried beyond the fourth decimal.

But notwithstanding the high state of perfection to which the mechanical arts have arrived, the mathematical equality of the length of the arms, and their symmetry in respect of the axis of motion, can never be practically attained; it is therefore desirable to have the means of obtaining results in as great a degree as possible independent of such extreme precision. The following method of weighing, ascribed by the French writers to Borda, gives results not affected by the inequality of the arms, or other imperfections to which the balance is principally subject, and ought to be practised whenever very great accuracy is necessary. Let the body to be weighed, which we shall call P, be placed in the scale A, and for a counterpoise put into the scale B, substances of any sort, for instance bits of copper, lead, wire, or even chips of paper, added in small quantities till the beam becomes perfectly horizontal, which is known by the index pointing to zero. This being done, remove gently the body P from A, and substitute for it known weights, as grains and fractions of a grain, till the equilibrium is restored, and the index again settles at zero. Now it is evident that the weights in A, having been placed exactly in the same circumstances with the body P, and producing equally with it an equilibrium with the loaded scale B, must be the exact equivalent or weight of P. In fact, the accuracy of this process can only be affected by two circumstances; the

Balance. first is, the friction of the axis, or the want of sensibility in the balance; and the second is, a change of position in the point of suspension. Unless the points of suspension are identical in both operations, the weights which successively produce equilibrium with B will not be exactly equal; for even if no change takes place in the length of the arm, the friction developed at the new points of contact will have a different value, and consequently require a different force to overcome it. The chief objects to be attended to, therefore, in practising the method of double weighing, are, that the mode of contact may receive no change during the loading and unloading of the scales; and that the friction may be reduced to its least possible value by giving the finest polish to the edges, as well as the plane of support.

With regard to the weights that ought to be employed, it may be sufficient to state, that, in delicate weighing, and for philosophical purposes, they are usually reckoned by Troy grains. The geometrical series 1, 2, 4, 8, 16, &c. offers one considerable advantage, namely, that a smaller number of weights is required than when any other system is adopted; but it would, perhaps, be more convenient in practice to follow the decimal division, and use weights of the following values: 1, 2, 3, 4, &c.; 10, 20, 30, 40, &c.; 100, 200, 300, 400, &c.; 1000, 2000, 3000, 4000, &c., up to 9000; and ·1, ·2, ·3, ·4, &c.; ·01, ·02, ·03, 0·4, &c.; ·001, ·002, ·003, ·004, &c. By this means the trouble of adding would be entirely avoided, and the number of weights in the scale would equal the digits in the number by which the grains are expressed. Thus a load of 735·4 grains would be counterpoised by weights of 700 grains, 30 grains, 5 grains, and 4-10ths of a grain.

See Euler, *Comment. Petrop.* tom. x. p. 3. *Phil. Trans.* for 1766; Shuckburgh in ditto for 1798, part 2d; Prony, *Annales de Chimie*, tom. xxxvi. p. 3; Biot, *Traité de Physique*, tom. i. p. 9; Ure's *Dictionary of Chemistry*; Leslie's *Elements of Natural Philosophy*, vol. i. p. 185.

The *Steelyard* is a balance by which the weights of bodies are estimated by means of a single weight. This machine, which is represented by fig. 5, is likewise a lever of the first kind, having two unequal arms. The load L to be weighed is suspended from the extremity of the short arm CA, and the counterpoise or constant weight P is movable along CB. Divisions traced on CB indicate the weight of L corresponding to each of the positions of P. In the East, where the steelyard is much in use, the standard weight P is generally made to resemble a pomegranate in shape; whence the instrument acquired the name of *Romman*, and from this circumstance it has frequently but erroneously been denominated the *Roman* balance or *Statera*.

To find the points of division of the arm CB, let W be the weight of the bar AB, exclusive of L and P; and let p be the weight in pounds of the body L. Let $CA = l$, and x be the unknown distance of the centre of gravity of the beam from the fulcrum C. Then, carrying P along the arm CB till the beam is horizontal, let A_1 be the point at which P rests, and put $CA_1 = X_1$. Now, the beam is kept in equilibrium by its own weight acting at the centre of gravity x, and by the weights p and P acting respectively at A and A_1; therefore the condition of equilibrium is expressed by the equation

$$W x + pl + PX_1 = 0.$$

Let another weight p, equal to the former, be suspended from A, and let A_2 be the position of P when the equilibrium is restored. Make $CA_2 = X_2$, and the above equation now becomes

$$W x + 2pl + PX_2 = 0.$$

In this manner, by the successive addition of equal weights p to A, the following system of equations is formed:

$$\begin{aligned} W x + \ \ pl + PX_1 &= 0 \\ W x + 2pl + PX_2 &= 0 \\ W x + 3pl + PX_3 &= 0 \\ \cdots\cdots\cdots & \\ W x + npl + PX_n &= 0. \end{aligned}$$

Balance.

By subtracting the first of these equations from the second, the second from the third, and so on, we have

$$\begin{aligned} pl + P(X_2 - X_1) &= 0 \\ pl + P(X_3 - X_2) &= 0 \\ pl + P(X_4 - X_3) &= 0 \\ \cdots\cdots\cdots & \\ pl + P(X_n - X_{n-1}) &= 0. \end{aligned}$$

The successive differences $X_2 - X_1$, $X_3 - X_2$, &c. are therefore constant, each being equal to the constant quantity $\frac{pl}{P}$. The divisions of the arm CB may therefore be found as follows:

Having suspended the given weight p from the extremity of the shorter arm CA, find the point A_1 at which it is necessary to place P in order that the beam may be horizontal. Then, having removed p, substitute for it another weight, which is an exact multiple of p, as np, and let P be moved toward C till the equilibrium is restored, A_n being the point where P is now placed. Divide the distance $A_1 A_n$ into $n - 1$ equal parts, and the points of division will be respectively those at which P will balance the intermediate weights between p and np. If, therefore, each of those points is marked with the corresponding value of p, the weight of any body whatever suspended from A will be indicated by the number of the division at which P rests when the beam is horizontal. The distances $A_1 A_2$, $A_2 A_3$, &c. may be divided into tenths, or other fractional parts.

For weighing heavy loads the steelyard is a convenient instrument; but for small weights it is not susceptible of so much accuracy as the common balance. The pressure on the fulcrum, and consequently the friction, is greater, when the commodities to be weighed are less than the constant weight P, and the subdivision of the arm cannot be effected with the same precision as that of weights for the balance. It may be proper, however, to remark, that the instrument ought to be constructed so that the constant centres C and A may be in the same straight line with the divisions of the beam, and that the centre of gravity of the unloaded beam, when placed horizontally, shall be in the vertical passing through C, and a little below that point, as in the common balance. An index or tongue shows when the beam takes the horizontal situation.

The *Chinese Balance* is a sort of steelyard for weighing small commodities, formed of a slender tapering rod of wood or ivory, about a foot in length, perforated generally with four holes through which silk threads are passed, to serve as so many points of support. Four different sets of divisions are marked on the corresponding sides of the rod; and when any thing is to be weighed, the rod is held up by one of the strings, and a sliding weight of about 1½ ounce Troy employed as a counterpoise to the substance, which is placed in a small scale suspended from the extremity of the shorter arm. The position of the standard weight indicates the weight of the substance, as in the ordinary steelyard.

The *Danish* or *Swedish Balance*, which is commonly employed in many parts of the north of Europe for weighing coarse commodities, is of a very simple construction. It consists usually of a batten of hard wood, having a heavy lump A (fig. 6) fixed at one end, and a swivel hook at the other. The goods to be weighed are fixed to the hook, and the whole is suspended in a loop of whipcord C, in which the rod is slid backward and forward

Balance. till the equilibrium is established. The weight of the load L is determined by the position of the loop on a scale of divisions, which may be formed in the following manner.

Let O be the centre of gravity of the beam and the attached weight at A, W their weight, L the load to be weighed, and make BO = a, BC = x. The equation of equilibrium is $Lx = W(a - x)$, whence $x = \frac{Wa}{L + W}$. Now, if we suppose a to be 30 inches, W = 2 lbs., and substitute for L the numbers 1, 2, 3, &c. successively, we shall have the following values of x:

When L = 1, x = 20 inches
L = 2, x = 15
L = 3, x = 12
L = 4, x = 10
&c.

A balance constructed in this manner is obviously susceptible of very little accuracy.

The *Bent Lever Balance*, which is represented by fig. 7, is sometimes employed for expedition in the coarser processes of weighing. To one extremity of a bent lever ACB, is attached a constant weight B, which acts as a counterpoise to the load placed in the scale suspended from A. Through C, the point of support, draw the horizontal line DE, and through A and B the perpendiculars AD, BE, meeting DE in D and E. Now the equilibrium will take place when CE is to CD as the load at A to the constant weight B; and if the arms are bent so that the lines joining CA and CB are at right angles, then as B moves upward, its momentum increases in proportion to the sine of the arc it describes, while the momentum at B decreases in proportion to the cosine of a similar arc. The weight on A corresponding to any position of B, may therefore be expressed on a graduated circular scale placed behind the index at B. Theoretically considered, the range of this balance is very considerable; but the indications are little to be depended on when B approaches either the perpendicular or the horizontal line passing through C.

The *Hydrostatic Balance* is an instrument contrived for weighing bodies in water, and thereby determining their specific gravities.

It is constructed in various forms; but we shall content ourselves here with describing that which appears of all others the most accurate. VCG (fig. 8) is the stand or pillar of this hydrostatic balance, which is to be fixed in a table. From the top A hangs, by two silk strings, the horizontal bar BB, from which is suspended, by a ring *i*, the fine beam of a balance *b*, which is prevented from descending too low on either side by the gently springing piece *txyz*, fixed on the support M. The harness is annulated at *o*, to show distinctly the perpendicular position of the examen, by the small pointed index fixed above it.

The strings by which the balance is suspended, passing over two pulleys, one on each side of the piece at A, go down to the bottom on the other side, and are hung over the hook at *v*; which hook, by means of a screw P, is movable about one inch and a quarter backward and forward, and therefore the balance may be raised or depressed so much. But if a greater elevation or depression be required, the sliding piece S, which carries the screw P, is readily moved to any part of the square brass rod VK, and fixed by means of a screw.

The motion of the balance being thus adjusted, the rest of the apparatus is as follows. HH is a small board, fixed upon the piece D, under the scales *d* and *e*, and is movable up and down in a low slit in the pillar above C, and fastened at any part by a screw behind. From the point in the middle of the bottom of each scale hangs, by a fine hook, a brass wire *ad* and *ac*. These pass through two holes *m*, *m*, in the table. To the wire *ad* is suspended a cylindric wire *rs*, perforated at each end for that purpose. This wire *rs* is covered with paper, graduated by equal divisions, and is about five inches long. Balance.

In the corner of the board at E is fixed a brass tube, on which a round wire *hl* is so adapted as to move neither too tight nor too free, by its flat head I. Upon the lower part of this moves another tube Q, which has sufficient friction to make it remain in any position required. To this is fixed an index T, moving horizontally when the wire *hl* is turned about, and therefore may be easily set to the graduated wire *rs*. To the lower end of the wire *rs* hangs a weight L; and to that a wire *pn*, with a small brass ball *g* about one fourth of an inch diameter. On the other side, to the wire *ac*, hangs a large glass bubble R, by a horse hair.

Let us first suppose the weight L taken away, and the wire *pn* suspended from S; and, on the other side, let the bubble R be taken away, and the weight F suspended at *c* in its room. This weight F we suppose to be sufficient to keep the several parts hanging to the other scale in equilibrium; at the same time that the middle point of the wire *pn* is at the surface of the water in the vessel O. The wire *pn* is to be of such a size that the length of one inch shall weigh four grains.

Now, it is evident, since brass is eight times heavier than water, that for every inch the wire sinks in the water it will become half a grain lighter, and half a grain heavier for every inch it rises out of the water: consequently, by sinking two inches below the middle point, or rising two inches above it, the wire will become one grain lighter or heavier. Therefore if, when the middle point is at the surface of the water in equilibrium, the index T be set to the middle point *a* of the graduated wire *rs*, and the distance on each side *ar* and *as* contains 100 equal parts; then, if in weighing bodies the weight is required to the hundredth part of a grain, it may be easily had by proceeding in the following manner.

Let the body to be weighed be placed in the scale *d*. Put the weight X in the scale *e*; and let this be so determined, that one grain more shall be too much, and one grain less too little. Then, the balance being moved gently up or down by the screw P, till the equilibrium be nicely shown at *o*, if the index T be at the middle point *a* of the wire *rs*, it shows that the weights put into the scale *e* are just equal to the weight of the body. By this method we find the absolute weight of the body; the relative weight is found by weighing it hydrostatically in water, as follows.

Instead of putting the body into the scale *e*, as before, let it hang with the weight F at the hook *c* by a horse hair, as at R, supposing the vessel O of water were away. The equilibrium being then made, the index T standing between *a* and *r* at the 36 division, shows the weight of the body put in to be 1095·36 grains. As it thus hangs, let it be immersed in the water of the vessel N, and it will become much lighter; the scale *e* will descend till the beam of the balance rest on the support *z*. Then, suppose 100 grains put into the scale *d* restore the equilibrium precisely, so that the index T stand at the 36 division above *a*, it is evident that the weight of an equal bulk of water would in this case be exactly 100 grains.

The *Balance of Torsion* is an instrument invented by Coulomb, for comparing the intensities of very small forces. It consists essentially of a metallic wire, suspended vertically from a fixed point, to the lower end of which a horizontal needle is attached, with a small weight for the purpose of keeping the wire stretched. The intensity of any small force made to act on the extremity of

Balance ‖ Balance of Power.

the needle is measured by the arc which the needle passes over, reckoned from the point of repose. The force is thus balanced by the *torsion* of the wire, whence the name of the instrument.

To prevent any derangement from the agitation of the air, the apparatus must be covered by a glass cylinder, to which a circular scale is applied horizontally, for the purpose of measuring the amplitude of the arc traversed by the needle. A divided circle is also adapted to the top of the cylinder, and capable of being turned round on it, by means of which, and a fixed index attached horizontally to the hook from which the wire is suspended, the wire may be twisted any required number of degrees. This apparatus is represented by fig. 9. The length of the wire and the needle must be regulated by the object in view. If the forces to be measured are very small, and great sensibility is consequently required, the wire must be long and very fine; for the force of torsion is inversely proportional to the length of the wire, and directly as the fourth power of its diameter. It must also be formed of a substance possessing considerable elasticity, and for this reason brass wire is greatly superior to iron. By experiments undertaken for the purpose, Coulomb found the elasticity of some wires so perfect, that on keeping them twisted through eight circumferences for thirty hours together, the centre of torsion was not displaced by a single degree. Their length was about a metre, or 39 inches.

Balance ‖ Balance of Power.

The balance of torsion is used chiefly in experiments on electricity, magnetism, the adhesion of fluids, &c.; and it was by means of this instrument that Cavendish made his famous experiments on the attraction of lead balls, from which he deduced the mean density of the earth equal to about 5·5, that of water being unit. (T. G.)

BALANCE OF POWER,

Among states, a most important principle of foreign policy, intimately connected with the general peace and independence of nations, but which some have treated as altogether chimerical, and others represented as having led only to pernicious results. It is more generally admitted, however, to have a real foundation in the rules of intercourse and union among states, and to have exercised a great and beneficial influence on the affairs of modern Europe. We say of modern Europe, because, though the policy in question was not wholly unknown to other ages and countries, it was nowhere *systematically* pursued but among the European nations of modern times. Previous to the sixteenth century there was little political connection among those nations, their circumstances not being such as to admit of any regulated attention to foreign affairs; but about the commencement of that century they began to form one grand community or federal league, of which the actuating principle was the preservation of the balance of power. The attention to this principle thenceforth influenced all the great wars and negociations, and made every foreign movement, however remote, an object of interest throughout every part of the European system.

We shall endeavour to sketch a general outline of this important subject; and, in doing so, we shall notice, though in a brief way, all the principal topics which it seems to present for discussion.

Principle of a balance of power, and system founded on it.

1. The ultimate intention of the system founded on the balance of power, is to secure every state in the full possession and enjoyment of all its rights, by making its safety and independence objects of interest and guardianship to its neighbours. It endeavours to accomplish this great end by teaching that it is the interest of all states to check the first encroachments of ambition, to watch every movement of foreign powers, and to unite their respective forces in support of the weak against the strong. It is called the balancing system, because its aim is to prevent any state from aggrandizing itself at the expense of its neighbours, and to counterpoise any state that may have become too powerful, by a union of the forces of others.

The metaphorical terms applied to this system seem to have given rise to some very absurd misconceptions of its true theory and purposes. It has sometimes been supposed that its object was to *equalize* the powers of states composing a common system; and as it is plainly impossible either to effect or to maintain such an equality, it has thence been concluded, that the whole system is founded upon a chimera. But, with a view to the objects of this system, the question is, not what amount of power above another any state possesses, provided the power so possessed be fairly acquired, but whether any state possesses its power in such circumstances as to enable it to trespass at pleasure on a weaker neighbour. If there be no other state, or confederacy of states, capable of counteracting any injurious designs which a greater power might undertake, then it is said there is no balance; but if there be such a counterpoise, this is all that the balancing system requires to produce what, in its language, is called an equilibrium. In order to make this point as clear as possible, we beg to refer to the following definitions of the balance of power, as given by Vattel and by Gentz: "By this balance," says the former, "is to be understood such a disposition of things, as that no one potentate or state shall be able absolutely to predominate and prescribe laws to the others." (*Law of Nations*, b. iii. c. iii. § 47.)—"What is usually termed a balance of power," says M. Gentz, "is that constitution subsisting among neighbouring states, more or less connected with one another, by virtue of which no one among them can injure the independence or essential rights of another, without meeting with effectual resistance on some side, and, consequently, exposing itself to danger." (*Fragments on the Political Balance*, c. i.)

Thus, then, it is distinctly understood that the balancing system is not grounded upon an *equality* among states in respect of power, but upon a union of powers to repress the enterprises of the strong and ambitious, and to counteract the effects of necessary individual inequalities by aggregate strength.

It is quite indispensable to the existence of such a system, that one state should not be permitted to obtain such a superiority of power as to enable it to overawe all opposition, and make the safety of those around it dependent on its will; and as it is the disposition of all unchecked power to extend itself, the balancing system inculcates it as the interest, as well as the right, of every state to join in opposing the first encroachments of any ambitious potentate or community. It teaches that the danger extends much further than to the party immediately attacked or menaced; that one encroachment will pave the way to another; and that it is therefore wise to meet the danger whilst yet distant, and capable of being combated with less peril or loss. The right of interference to put down a danger of this kind is, in fact, only a modification of the right to resist an immediate attack. All human experience shows, that the state which is suffered to aggrandize itself at the expense of one neighbour, will with

Balance of Power.

its increased means acquire stronger dispositions to encroach still further; and therefore self-defence authorizes us to treat as already an invader, any potentate whose conduct entitles us to conclude that he only waits a convenient opportunity to become so in effect. "As long," says Bacon, "as men are men, and as long as reason is reason, a just fear will be a just cause of a preventive war; but especially if it be part of the case that there be a nation that is manifestly detected to aspire to new acquests, then other states assuredly cannot be justly accused for not paying for the first blow, or for not adopting Polyphemus's courtesy, to be the last that shall be eaten up." (*Speech concerning a War with Spain.*) It is peculiarly and emphatically the language of the balancing system, *Principiis obsta*,—in other words, look well to the safety and independence of your neighbours, even the most remote, if you wish to preserve your own.

Upon this point it is by no means necessary to enter into any lengthened deductions. The principle of interference to prevent the progress of a dangerous power rests, both as to right and policy, upon the most obvious dictates of experience and prudence. No state ever yet acquired a preponderating power without abusing it; and therefore it is the right and interest of all states to prevent any one from rising to such an ascendency as may endanger the common safety.

The right in question, however, is that of guarding against injury justly to be apprehended from the conduct of a state which uses improper means of aggrandizement. As far, therefore, as measures of hostility are concerned, there must be actual encroachment in order to warrant them. The balancing system does not say there shall be no alterations in the relative strength of states; for a state may fairly and honourably increase her power by wise legislation, or by the cultivation of her own internal resources. To attempt to impede a state which takes this road to greatness, would be to make war upon those very arts by the successful cultivation of which peace and happiness are spread throughout the world. The aggrandizements to which the balancing system stands opposed, are those attended with immediate violence to some, and which infer further violence to others. All that nations can do when a neighbour becomes formidable in a fair way, is to watch her, and to draw closer those ties of alliance which may enable them to counteract any bad use of her power. When Lord Bacon, in his *Essay on Empire*, counsels princes "to keep due sentinel, that none of their neighbours do so overgrow by increase of territory, by *embracing of trade*, by approaches or the like, as to become more able to annoy them than they were," he does not mean that the growth of a state by commerce is to be prevented in the same way as in the case of its extension by a seizure of territory, but, that all great power, however acquired, is in its nature dangerous, and ought to be counterpoised by timely confederation.

There is another way in which a state may become formidable, and that of a sudden, where the balancing system does not authorize immediate hostile interference. We allude here to the case of a sovereign who acquires a great accession of power by marriage or by inheritance. "It is a sacred principle of the law of nations," says Vattel, "that such an increase of power cannot, *alone and of itself*, give any one a right to take up arms in order to oppose it." (B. iii. c. 3, sect. 43.) Grotius and Puffendorf maintain the same opinion in terms equally decided. But, suppose a sovereign, who has already displayed an encroaching disposition, is about to acquire in this way an accession of power, which would render him more and more formidable to his neighbours; in this case, as Vattel shows, the maxims of the balancing system authorize an immediate interference to procure securities; or, according as the danger is imminent, altogether to prevent the impending aggrandizement. It is perhaps wholly unprecedented, as this writer observes, that a state should receive any remarkable accession of power, without giving other states just grounds to interfere; but if it should be otherwise, the only course to be pursued is that which the balancing system recommends, namely, to keep a watchful eye on all the proceedings of the formidable state, and the formation of a counterpoise by means of alliances.

Balance of Power.

These, then, are the grand expedients of the balancing system: vigilant inspection to discover, and prompt union to counteract, in their birth, all such projects of encroachment as powerful states will ever, when opportunity offers, be ready to form. By employing resident agents to procure speedy information, and by the weight of joint warnings and reclamations in every case of apprehended or of real injury, the balancing system furnishes the only peaceful means which human wisdom can devise to control the conduct of independent states; the only means which can be employed to guard against injustice, or obtain redress, without an actual appeal to the sword. It was the *habitual* employment of these expedients, with a view to guard against distant dangers, that distinguished the balancing system, as exemplified in modern Europe, from those momentary efforts and loose confederacies in which all nations, and even the rudest tribes, have occasionally united, in order to repel or pull down a powerful and common enemy.[1] Without this habitual attention to foreign affairs, and constant application of the principles of counterpoise, there cannot, indeed, be said to exist any thing like a system of reciprocal guarantee of the independence of nations, such as is involved in the idea of a balance of power.

What particular alliances each state ought to form, with a view to maintain this balance, is a matter of circumstances, and must accordingly vary with them. The object of the system is always the same,—to preserve such a distribution of power amidst the varying relations of states, as shall most effectually check the spirit of encroachment, and confine every potentate to his own dominions.

In the preceding observations we have had it in view to give a general idea of the nature, intention, and means of maintaining a balance of power among a number of connected nations of different degrees of power and magnitude. But before proceeding to any remarks on the history and results of this branch of policy, we shall recapitulate, in the words of M. Gentz, those fundamental maxims which constitute the necessary conditions of the beneficial existence of such a system as we have described. These are,—

"That no one state in the common system must ever become so powerful as to be able to coerce all the rest put together;—

"That, if the system is not merely to exist, but to be maintained, without constant perils and violent concus-

[1] "The grand and distinguishing feature of the balancing system is the perpetual attention to foreign affairs which it inculcates; the constant watchfulness over every nation which it prescribes; the subjection in which it places all national passions and antipathies to the fine and delicate view of remote expediency; the unceasing care which it dictates, of nations most remotely situated, and apparently unconnected with ourselves; the general union which it has effected of all the European powers obeying certain laws, and actuated in general by a common principle; in fine, the right of mutual inspection, universally recognized among civilized states in the rights of public envoys and residents." (Brougham's *Colonial Policy*, b. iii. sect. 1.)

Balance of Power.

sions, every member which infringes it must be in a condition to be coerced, not only by the collective strength of the other members, but by any majority of them, if not by one individual;—and,

"That if ever a state attempts, by unlawful enterprise, to attain, or does in fact attain, to a degree of power, which enables it to defy the danger of a union of several of its neighbours, or even of the whole, such a state should be treated as a common enemy; and if it has acquired that degree of force by an accidental concurrence of circumstances, without any acts of violence, whenever it appears upon the public theatre, no means which political wisdom can devise for the purpose of diminishing its power should be neglected or left untried." (*Fragments upon the Political Balance*, c. 1.)

Ancient knowledge of the balance of power, and rise of the modern system.

2. The knowledge of the ancients in regard to these great principles of national safety, and the period when they came to obtain a decided influence among the moderns, are points of considerable historical interest. Mr Hume has proved, in a very satisfactory manner, that the principle of preserving a balance of power is distinctly to be recognised in many of the great political transactions of the ancient world. The same thing had previously been shown by Kahle, a famous physician and professor, in a learned and able work, of which a French translation by Formey, entitled *La Balance de l'Europe*, was published at Berlin in 1744. The anxiety of the Greeks with regard to the principle of equilibrium among states was particularly manifested in that famous league against the rising power of Athens which produced the Peloponnesian war. Athens herself showed that she both knew and practised this policy, by constantly throwing her power into the lighter scale, when Thebes and Sparta came to contend for the mastery of Greece. Mr Hume also traces the influence of this salutary principle in the contests which arose among the successors of Alexander; their attention to it having "preserved distinct, for several ages, the partitions made after the death of that conqueror." (*Essays*, vol. i.) The orations of Demosthenes frequently display very clear and extensive views in this branch of policy. In that for the Megalopolitans, in particular, "we may see," according to Mr Hume, "the utmost refinements in the balance of power that ever entered into the head of a Venetian or English speculatist;" and by a later writer this speech is also pointed out as "containing discussions of some of the most delicate parts of the theory." (Brougham's *Colonial Policy*, b. iii. sect. 1.) All who peruse this remarkable oration with due attention must indeed perceive that it fully bears out this character. Its reasonings may be analyzed into these leading doctrines of the balancing system: that it is the interest of every state to prevent the formation of a predominating power; that to this end the first encroachments ought to be promptly checked; and that it is necessary to join even a rival against a former friend, when that friend would otherwise infringe upon the balance.[1]

It seems, in short, to be no longer a question, that it was only with the *phrase*, and not the *idea*, of a balance of power, that the ancients were unacquainted. But we cannot agree with Mr Hume when he goes so far as to say that this principle, though it has been more generally known and acknowledged in modern times, has not had an authority much more extensive in practice, than it had among the nations of antiquity. (*Essays*, vol. i.) This opinion stands clearly refuted by all the great facts, and by the whole tenor of modern history, from the commencement of the sixteenth century. It was the more constant operation of the principle in question which gradually formed the nations of Europe into one great republic or federal league, whose common bond of union was the guarantee which it afforded of their respective independence. But neither, on the other hand, can we agree with Mr Brougham, when he affirms that the ancient states displayed nothing beyond a mere speculative knowledge in this department. (*Colonial Policy*, b. iii. § 1.) It may be very true that those more enlarged ideas of foreign policy which Demosthenes disclosed in some of his orations were not generally understood or acted upon by his contemporaries; but it is nevertheless perfectly clear, from Mr Hume's statements, the accuracy of which has never been called in question, that among the Grecian states the maxim of preserving a balance of power, though it had not produced any course of policy so regular and authoritative as the modern international system, was yet, on many occasions, the sole moving spring of their wars and alliances.

Balance of Power.

This maxim, indeed, lies so much within the sphere of common sense, that it can scarcely fail to be attended to, wherever there is a collection of states capable of observing and attacking each other. But circumstances may be more or less favourable to the growth of a consistent policy in this respect. In modern Europe, a number of considerable states were formed under such circumstances as tended peculiarly to promote a regular intercourse among them, and consequently to develope and systematize this great principle of national security. But it did not begin to manifest itself until, in the gradual and similar progress of European society, the power of the sovereigns of these states was so far consolidated as to enable them to give part of their attention to foreign affairs, and to maintain armies beyond their own frontiers. It was in Italy, where civilization was more advanced, and where there existed a number of small states and commonwealths whose safety required that their rulers should reciprocally keep watch on each other, that the modern system of interference took its beginnings. From an early period of the fifteenth century, we see the balance of power as constant an object of concern among these states as, in the next, it came to be throughout Europe. "Their jealousy of each other," says Guicciardini, "made them watchful of every motion or measure which they conceived might any way increase the power of their neighbours;" and he presents a splendid picture of the beneficial effects, the long peace, and general independence, attendant upon this habitual attention to the balancing principle. (*History of Italy*, b. i.)

It was about the end of the same century that these ideas began to extend to other quarters, and to actuate the movements of greater potentates. There were now several princes possessed of large kingdoms, with powers and prerogatives which enabled them to take part in distant wars and negociations. The first great movement of an ambitious neighbour would naturally, therefore, excite their jealousy, and bring them into concert. Thus, when Charles VIII. of France, in 1494, invaded Italy and laid claim to Naples, the sovereigns of Germany and Spain saw the expediency of listening to the Italian princes, who suggested a confederacy to prevent France from gaining an accession of power which could not but render her a dangerous neighbour. Dr Robertson regards

[1] There is a passage of Polybius, which has been frequently quoted as pointing out the leading aim of the balancing system in terms the most explicit. The historian, after mentioning that Hiero, king of Syracuse, acted wisely in assisting the Carthaginian in the war of the auxiliaries, adds, "Nunquam enim ejusmodi principia contemnere oportet, neque tanta cuiquam astruenda es potentia, ut cum eo postea de tuo quamvis manifesto jure disceptare ex æquo non queas." (Lib. i. cap. 83.)

Balance of Power.

the expedition of Charles as the first great exertion of those new powers with which the progress of society had invested the princes of Europe; and views the confederacy formed against him, as the first considerable extension of those ideas of a balance of power whose influence had hitherto been limited to the narrow sphere of Italian politics. "From this era," he says, "we can trace the progress of that intercourse between nations which has linked the powers of Europe so closely together, and can discern the operations of that provident policy which, during peace, guards against remote and contingent dangers, and in war has prevented rapid and destructive conquests." (*View of the Progress of Society in Europe*, § 2.) If we look only a little later, we shall everywhere see a constant jealousy of the increase of power, and a vigilant attention to all foreign operations, combined with the application of those means of safety which peculiarly distinguish the balancing system. "During that triumvirate of kings," says Lord Bacon, in his usual expressive language, "Henry VIII. of England, Francis I. of France, and Charles V., Emperor, there was such a watch kept, that none of the three could win a palm of ground, but the other two would straightways balance it, either by confederation, or, if need were, by a war; and would not, in any wise, take up peace at interest." (*Essays on Empire.*)

It has been objected to Dr Robertson that he has represented "the principle of the balance of power as a *discovery* made by the Italian politicians in *consequence* of this invasion of Charles; whereas it was not to any such single event that the balancing system owed either its origin or refinement, but to the progress of society, which placed the whole states of Europe in the same relative situation in which the states of Italy were at that period, and taught them not to wait for an actual invasion, but to see a Charles at all times in every prince or commonwealth that should manifest the least desire of change." (Brougham's *Colonial Policy*, b. iii. § 1.) What is here said as to the origin of the balancing system is no doubt true. We have already stated that the principle on which it rests is a principle of our common nature, which cannot fail to manifest itself in certain situations; but that nations must have arrived at an advanced stage of civilization and intercourse before it can be acted upon with consistency and concert. It would therefore be absurd to represent that system as taking its rise in any single event, or its principle as a discovery of some long-sighted statesman. But Dr Robertson knew human nature too well to seek the origin of this principle in an accidental occurrence; and he knew history too well to fix its origin "as a consequence" of Charles's invasion. On the contrary, throughout the whole of his masterly chapter on the progress of the nations of Europe, with respect to the command of the national force requisite in foreign operations, he speaks of this system as holding progress with the growing improvement and intercourse of these nations; and, so far from representing the principle of the balance of power as a discovery consequent upon the event alluded to, he expressly speaks of the league against the French monarch as only exemplifying an extension of those ideas which had long been familiar to the Italian statesmen "in regulating the operations of the petty states in their own country." (*View of the Progress of Society*, § 2.)

Before concluding these very general remarks on the rise of the balancing system in modern times, we shall briefly advert to a conjecture of M. Villers upon this subject, which occurs in his able work on the Reformation. Long before the states of Europe became united in a general system, Italy and Germany, he observes, had formed partial systems, with a view to restrain the members within them, each by the other, and thus maintain a balance of power. It is possible, he adds, that the idea of the *general* balance of Europe may have been copied from these partial confederacies. (*Essai sur l'Esprit et l'Influence de la Réformation*, 2de partie.) This conjecture, if we rightly understand the learned author, appears to us exceedingly unphilosophical. The states of Europe embraced the idea of a balance of power in proportion as their circumstances enabled them to act upon it, and not in consequence of any estimate of its effects, as displayed on those earlier and narrower stages of its agency.

Balance of Power.

3. It appears, then, to have been about the beginning of the sixteenth century that the principle of maintaining a balance of power came to be generally recognised and acted upon by the states of Europe; "at first," as M. Gentz says, "more in a practical way, and, as it were, from political instinct, but afterwards with clear, reflecting, and methodical constancy." (*Fragments.*) What the advantages were which Europe reaped from this course of policy we shall endeavour to show, after we have adverted to certain arguments generally employed by those who wish to give an unfavourable view of the balancing system.

General results and recent history of this system.

By some this system is represented as productive only of wars; as but a convenient pretext to cover projects of ambition, or to screen the restless movements of national jealousy. Others talk of it as being merely a brilliant conception, and appeal to the many violences and usurpations which modern history records, as proofs, if not of its nonentity, at least of its inefficacy. But there is surely no great respect due to that sort of estimate of the system which is founded solely on the abuses to which it is liable, or upon imperfections from which no human institution is free. They who decry or who ridicule the balancing system should be prepared to show, not that it has sometimes afforded plausible pretexts for unnecessary wars, or has sometimes failed to protect the weak against the outrages of the strong, but that it is wholly useless to interest ourselves in the safety of neighbouring nations; to take any trouble to avert dangers which are yet distant; or to seek to strengthen ourselves against a powerful enemy with any strength not our own. This view of things, were it to prevail, would, as M. Gentz observes, open the most desirable prospects to every sovereign whose power and ambition might prompt him to aspire to universal domination.

It must, we think, appear obvious to every one who reflects upon the subject, that the balancing system is, upon the whole, favourable to peace. The wars which peculiarly belong to it are in the nature of a sacrifice of a smaller present, to secure a greater future good; and the tendency of the system is to render these wars less and less frequent. The evil passions which give rise to ambitious attacks, like all other evil passions, will be more apt to be indulged the less exposed they are to opposition or restraint. And it cannot be questioned that, in proportion as the maxims of this system are vigilantly and steadily pursued, there will be less inducement, because less prospect of success, for ambitious undertakings.

Its object is to alarm, and to arm all against the prince whose power prompts him to transgress upon others; and the prince who knows that all his motions are keenly watched, and that his first successes would only expose him to a more extended contest, must see how hopeless would be any attempt to possess himself of the territories even of the weakest of his neighbours. Such is the general tendency of the system; and however it may have occasionally failed to prevent outrages, it cannot be doubted that it has proved a formidable barrier against conquest, and a rampart of defence to the weaker states.

Balance of Power.

The complaint of a certain class of French politicians, alluded to by Mr Burke in his *Letters on a Regicide Peace*, "that Rome had frequently acquired more territory in a *single year*, than all the power of France, actuated by all her ambition, had enabled her to acquire *in two centuries*," forms, in fact, though unintended, one of the finest panegyrics that could have been pronounced upon the salutary influence of the modern system. The advocates of that system can, indeed, appeal to history for the most satisfactory of all proofs of its efficacy, in the remarkable fact, that, for a period of nearly three centuries, no European state, however small, has lost its independence from external violence. When we recollect the number of small states which, during so long a period, enjoyed an independent existence in the immediate neighbourhood of powerful nations, and reflect for a moment on those evil passions which have, in all ages, prompted the strong to prey on the weak; we must admit that, but for that salutary jealousy of power, and united resistance to its encroachments, which it was the object and office of this system to nourish and enforce, these otherwise helpless states would have been speedily absorbed, or their independence annihilated, by the mighty masses with which they were in contact. It was not the preservation of such countries as Portugal or Holland, of Sweden or Denmark, which, though small compared with many others in the system, were yet possessed of considerable means of self-defence; —it was not the preservation of such states as these merely, but of a multitude of feeble communities in Germany, in Switzerland, and Italy, which affords the proudest proof of the salutary influence of the balancing system on the fortunes of modern Europe. "Consider, for instance," to use the impressive words of a distinguished writer and orator, "the situation of the republic of Geneva; think of her defenceless position in the very jaws of France; but think also of her undisturbed security, of her profound quiet, of the brilliant success with which she applied to industry and literature, while Lewis XIV. was pouring his myriads into Italy before her gates; call to mind that happy period when we scarcely dreamt more of the subjugation of the feeblest republic of Europe, than of the conquest of her mightiest empire; and say whether any spectacle can be imagined more beautiful to the moral eye, or which affords a more striking proof of progress in the noblest principles of true civilization." (Mackintosh's *Speech on the Trial of John Peltier, in* 1803.)[1]

Such were the results of the system founded on the balance of power. It was a bridle upon the strong and a bulwark to the weak. When it failed to prevent the inroads of violence and injustice, it yet acted as a restorative principle, and replaced injured nations in their former state of independence. It was at the memorable and fatal era of the partition of Poland in 1772 that it first lost this character; that the first example was set of a deliberate, successful, unchecked conspiracy against the independent existence of an unoffending country. It is here proper to mention, that some authors have spoken of this infamous transaction in terms which seem to imply that it was quite in consonance with the principles of the balancing system.[2] It is indeed true, that the maxims of that system were still so far operative as to effect a relative equality in the division of the spoil. But as the whole intention of this system is to maintain the integrity and independence of nations against unlawful attacks, the partition was just as diametrically opposite to its principle, as if the whole spoil had been appropriated by one robber, instead of being shared by three. The equality of the division did not take away from the danger of the example; the example of states combining, not to uphold, but to destroy,—not to enforce respect to the great principles of national safety, but to set them at defiance; an example too soon followed by similar violences, and which, in fact, paved the way for that total overthrow of the ancient system of Europe which ere long took place.

Balance of Power.

The *origin* of a project so pernicious in its consequences is a matter of some interest in the history of the balancing system. We learn from Rulhière's *Histoire de l'Anarchie de Pologne*, published in 1807, that the distractions of this country had suggested the project of a partition as early as 1658; that a Swedish minister, named Stippenbach, proposed it to his own court, to Austria, and the grand duke of Prussia, whose armies were then in possession of the country; and that it would, in all probability, have been acted upon but for the discovery of the scheme by France, and the consequent interference of that power.[3] With regard to the project actually carried into execution in 1772, each party concerned was desirous to shift the blame of the first proposal on the others; but it was generally believed to have originated with Frederick, though some were of opinion that he was indebted for the idea to his brother, Prince Henry. Frederick, however, in one of his posthumous pieces (*Mémoires de* 1763 *jusqu'à* 1775), states that the scheme was devised by the empress Catharine; and this is corroborated by M. Rulhière, who asserts that she communicated it to Prince Henry during his visit to St Petersburg in 1770; a piece of information, he adds, which was detailed to him in the most circumstantial manner, by three different secretaries, who

---

[1] We shall here add a striking passage in reference to our subject from this celebrated oration. "These small states were, in many respects, one of the most interesting parts of the ancient system of Europe. Unfortunately for the repose of mankind, great states are compelled, by regard to their own safety, to consider the military spirit and martial habits of their people as one of the main objects of their policy. Frequent hostilities seem almost the necessary condition of their greatness; and, without being great, they cannot long remain safe. Smaller states, exempted from this cruel necessity—a hard condition of greatness, a bitter satire on human nature—devoted themselves to the arts of peace, to the cultivation of literature, and the improvement of reason. They became places of refuge for free and fearless discussion; they were the impartial spectators and judges of the various contests of ambition which from time to time disturbed the quiet of the world. They thus became peculiarly qualified to be the organs of that public opinion which converted Europe into a great republic, with laws which mitigated, though they could not extinguish, ambition; and with moral tribunals to which even the most despotic sovereigns were amenable. If wars of aggrandizement were undertaken, their authors were arraigned in the face of Europe. If acts of internal tyranny were perpetrated, they resounded from a thousand presses throughout all civilized countries. Princes on whose will there were no legal checks thus found a moral restraint which the most powerful of them could not brave with absolute impunity. They acted before a vast audience, to whose applause they could not be utterly indifferent. The very constitution of human nature, the unalterable laws of the mind of man, against which all rebellion is fruitless, subjected the proudest tyrants to this control. No elevation of power,—no depravity, however consummate,—no innocence, however spotless,—can render man wholly independent of the praise or blame of his fellow-men."

[2] See, for example, the terms in which Count Hertzberg speaks of the partition, in his essay, *Sur la Balance du Commerce et celle du Pouvoir*. (*Œuvres*, tome i.) The language of M. Gentz upon this subject, in his able work, *L'Etat de l'Europe avant et après la Révolution Française*, is extremely exceptionable; but in his later work, referred to in this article, he condemns the partition as wholly inconsistent with, and as having in fact led to the subversion of, the balancing system.

[3] "J'ai retrouvé," says M. Rulhière, "dans les archives des affaires étrangères de France, cette anecdote importante, et jusqu'à présent ignorée." (Tom. i. p. 9.)

accompanied the prince to the Russian court. (Tome iv. p. 151–210.) It seems to be generally acknowledged, that the proposal, when first made to the cabinet of Vienna, was opposed by that power; and that her accession would not have been obtained but for the astonishing apathy displayed by France, and, indeed, by all the other states of Europe. The silence of England during the perpetration of this shameless plot against the independence of nations, if it can be accounted for, can never, at any rate, be excused; inasmuch as the fact appears pretty well established, that, had she, as the guardian of the political balance, raised her voice against the partition, Europe might have been saved from the fatal effects of that new system of robbery and oppression which the spoilers of Poland were suffered, without any sort of interruption, to exemplify. "To my certain knowledge," says Mr Burke, "if Great Britain had at that time been willing to concur in preventing the execution of a project so dangerous in the example, even exhausted as France then was by the preceding war, and under a lazy and unenterprizing prince, she would have at every risk taken an active part in this business." (*Thoughts on French Affairs in* 1791.)

Interest of Great Britain in the balancing system.

4. We have still to allude to the question, whether Britain, protected as she is on all sides by nature, ought to consider it as a necessary part of her policy to attend to the European balance of power? This has been considered as constituting a separate question, by some who make no doubt that the other states of Europe could not long preserve their independence secure by any other course. Taking the question generally, we do not think there is any great difficulty in regard to it. With the multitude, to be sure, it always will be popular to argue, that Britain stands in need of no other defence than what the seas and her invincible navy afford her, and that all continental connections are useless or pernicious. But the argument from the advantages of our insular situation would not in fact bear out this conclusion, even were the seas and the navy a stronger defence than it is possible they can always be. Our commerce and our colonies, the supports of that navy, render it indispensably necessary that we should more particularly observe some nations, and ally ourselves with others. These great concerns make it, indeed, nothing less than absurd to talk of our being *insulated* as an empire or state, because Britain is an island. And, with regard to invasion, it is clear that we could not always be as secure and as free from uneasy apprehensions, in a state of total insulation from foreign connections, as with friends and confederates to employ or oppose a formidable enemy on his own confines.

Balance of Power ‖ Balasore.

But supposing the balance of power to constitute a great national object, the line of conduct which that object imposes upon us may, no doubt, be affected by our insular situation. We may on some occasions allow other nations who are more exposed to danger, and who ought, on that account, to be more on the alert to prevent encroachments, to take the first measures, and bear the first expense of resistance. We may watch and warn, and use the influence of our remonstrances and our counsels, without having recourse, except in urgent cases, to the extremity of arms.[1] It is only, in a word, as to the *application* of the general principle, and not as to its being necessary and worthy to be entertained, that there seems any fair room for difference of opinion among British statesmen. In point of fact, all our later statesmen, however differing in other respects, have distinctly assented to the *general* doctrine, that the balance of power was an interest of the highest importance to England. The last time, we believe, that this question can be said to have been fairly brought into debate, and fully discussed in Parliament, was on occasion of the famous armament against Russia for refusing to restore Oczakov to the Porte; and on that occasion, though Mr Fox and his followers reprobated the armament in the strongest terms, they did so, not because they denied the great principle to which the minister appealed, as the sole justification of the measure, that the balance of power was a British concern, and gave Britain an undoubted interest to mingle in the affairs of the continent,—not because they thought that Britain ought never to guard against any distant danger,—but because there was no such degree of danger from the retention of that city and its district, as called upon this country to interfere at the risk of a war.[2] (M. N.)

Balance of Trade. See Political Economy.

Balas Ruby, a variety of spinel ruby. See Mineralogy.

Balasinore, in Western India, a town, the chief place of the native state of the same name, situate in the province of Guzerat. The territory of the ruling nawaub contains an area of 258 square miles, and a population of 19,000. In 1768 it was subjected to tribute by the Mahrattas, which, subsequently to 1818, when the peishwa was deprived of his supremacy, has been paid to the British. The town of Balasinore is distant from Bombay N. 280 miles; Lat. 22. 58. Long. 73. 20.

Balasore, a town and seaport of Hindustan, in the British district of Cuttack, within the province of Orissa. The town, which is long and straggling, is built along the banks of the Booree Bellaun River. The English, Dutch, French, and Danes, formerly had factories here; and traces of a Portuguese establishment are also to be found in the ruins of a small Roman Catholic chapel within the town. The English factory was burnt down in November 1688, when, on account of a rupture with Aurungzebe, Captain Heath attacked and plundered the town. Balasore is the principal port of the district, and is provided with dry docks on the banks of the river, to which vessels drawing not more than 14 feet water can be floated during spring tides. Balasore roads form an extensive bay, stretching from Point Palmyras to the mouths of the Hooghly; and as the navigation of this river to Calcutta is extremely dangerous, and requires skilful pilots, it is in these roads that those who

---

[1] "Other nations must watch over every motion of their neighbours; penetrate, if they can, every design; foresee every minute event; and take part, by some engagement or other, in almost every conjuncture that arises. But as we cannot be easily nor suddenly attacked, it may be our interest to watch the secret workings of the several councils abroad; to advise and warn; to abet and oppose; but it never can be our true interest easily and officiously to enter into action, much less into engagements that imply action and expense." (Bolingbroke's *Idea of a Patriot King.*)

[2] Earl Grey, when the only survivor of that illustrious group of orators and statesmen who opposed the armament, repeatedly and forcibly declared his adherence to the general doctrine; affirming, that though the epithets *wild* and *romantic* had sometimes been applied to it, he nevertheless considered the poorest peasant in England as interested in the preservation of the balance of power; and that this country ought to interfere whenever that balance appeared to be really in danger. Of all those who joined in this opposition, Mr Burke was the only statesman who did so upon a ground, as it appears to us, equally erroneous in *fact* and *principle*, namely, that Turkey never had been, nor ought to be, taken into consideration, in any question as to the maintenance of the balance of power in Europe. (See *Debates in the House of Commons*, 29th March and 12th April 1791, and 29th February and 1st March 1792.)

Balaton ‖ Baldinger.

undertake that service wait the arrival of vessels. Balasore town is distant 116 miles S.W. from Calcutta. Lat. 21. 30. Long. 87. (E. T.)

BALATON LAKE, or PLATEN ZEE, in the S.W. of Hungary, 55 miles S.W. of Pesth. It is 46 miles in length, but of varying width, with a surface of 110 square miles, exclusive of the extensive marshes by which it is surrounded.

BALBI, ADRIAN, one of the most eminent geographers of modern times, was born at Venice in 1782. In 1820 he visited Portugal, and there collected materials for his well-known work entitled *Essai Statistique sur le Royaume de Portugal et d'Algarve*, &c., which was published at Paris in 1822; and this was followed by *Variétés Politiques et Statistiques de la Monarchie Portugaise*. This work contains some curious observations respecting that country under the Roman sway, and on the state of literature and the arts. In 1826 he published the first volume of his *Atlas Ethnographique du Globe*, &c., a work of great erudition, and embodying the researches of the most distinguished German philologists and geographers. In 1832 appeared the *Abrégé de Geographie*, which comprises the whole compass of that science, and procured for the author the highest reputation. This work, in an augmented form, was translated into the principal languages of Europe. Balbi afterwards retired to Padua, where he continued to pursue his favourite science with unabated ardour. Besides those already mentioned, Balbi was the author of several other works in the same department of science. He died on the 14th of March 1848.

BALBOA, VASCO NUÑEZ DE. See PERU.

BALBRIGGAN, a seaport of Ireland, county of Dublin, and parish of Balrothery, 18½ miles N.N.E. of the capital. The harbour, though dry at low tides, has a depth of 14 feet at high-water springs, and affords a good refuge from the E. or S.E. gales. It is formed by a pier 600 feet long, with a lighthouse at its extremity, in Lat. 53. 37. N. Long. 6. 12. W. The town has considerable manufactures of cottons and hosiery, and is much frequented as a watering-place in summer. Pop. (1851) 2310.

BALDI, BERNARDINO, a distinguished mathematician and miscellaneous writer, was descended of a noble family at Urbino, in which city he was born on the 6th of June 1533. He pursued his studies at Padua with extraordinary zeal and success, and is said to have acquired, during the course of his life, no fewer than sixteen languages, though, according to Tiraboschi, the inscription on his tomb limits the number to twelve. The appearance of the plague at Padua obliged him to retire to his native city, where, some time afterwards, his acquirements were the means of his obtaining from Ferrante Gonzaga the rich abbey of Guastalla. He afterwards visited Rome, where he was honoured with the title of apostolic protonotary. Returning to Urbino, he was employed by the duke, in 1612, as his envoy to Venice, where he distinguished himself by the congratulatory oration he delivered before the Venetian senate on the election of the new doge, Andrea Memmo, who on this occasion presented Baldi with a massive gold chain. Shortly afterwards he resigned the cares of his abbey, and retired into a private station, but he did not long survive this event. He died at Urbino on the 12th of October 1617. Baldi was perhaps the most universal genius of his age, and is said to have written upwards of a hundred different works, the chief part of which have remained inedited. His various works are evidence of his abilities as a theologian, canonist, mathematician, geographer, philosopher, antiquary, historian, orator, and poet. His life has been written by Affò, Mazzuchelli, and others. Baldi's *Coronica dei Matematici* is an abridgment of a larger work on which he had bestowed twelve years of labour, and which was intended to contain the lives of more than two hundred mathematicians.

BALDINGER, ERNST GOTFRIED, a German physician of considerable eminence, and the author of a great number of medical publications, was born near Erfurth, 13th May 1738. He was originally destined for the church; but having acquired a strong predilection for medicine, his father yielded to his wishes, and with this view he prosecuted his studies at Erfurth, Halle, and Jena. In 1761 he was intrusted with the superintendence of the military hospitals connected with the Prussian encampment near Torgau; and he there gave public lectures with great applause. Having acquired considerable experience in army practice by his assiduous attention to the duties of his office, he published, in 1763, a dissertation on the diseases of soldiers, which met with so favourable a reception from the public, that he enlarged the plan of his work, and republished it under the title of *Treatise on the Diseases that prevail in Armies*, Langensalz, 1774, 8vo. In 1773 he was appointed professor of medicine at Göttingen, where he enjoyed considerable reputation. He was afterwards professor of the theory of medicine at Jena; and in 1785 was promoted to a professorship at Marpurg, where he died of apoplexy on the 21st of January 1804. Among the number of his pupils were Akermann, Sömmering, and Blumenbach.

Baldinucci ‖ Baldwin.

His writings are exceedingly numerous: many of them are scattered in various collections and journals. No less than eighty-four distinct treatises are mentioned as having proceeded from his pen. He had collected an extensive library, consisting of 16,000 volumes, of which a catalogue was published after his death.

BALDINUCCI, FILIPPO, a distinguished Italian writer on the history of the arts, was born at Florence about 1624. His chief work is entitled *Notizie de' Professori del Disegno da Cimabue in quà, Secolo v. dal* 1610 *al* 1670, and was first published in six vols. 4to, in 1681–8. An edition in twenty vols. 8vo, with notes by Manni, was published at Florence in 1767–74. The capital defect of this work is his puerile attempt to derive Italian art from the schools of Florence; in which he has been often refuted, especially by Malvasia and Lanzi. Baldinucci died in 1696.

BALDOCK, a market-town of England, county of Hertford, and hundred of Broadwater, 37 miles N. of London. It is pleasantly situated in a valley on the Great North Road, and is well paved and lighted. Its principal street has several handsome buildings. The church is a spacious edifice, with a spire, three chancels, a curious font, and some monuments of its founders the Templars. There are also places of worship belonging to the Methodists, Independents, and Quakers; and several schools, almshouses, and other charities. Manufactures, beer, malt, and straw-plait. Pop. (1851) 1920.

BALDOCK, *Ralph de*, bishop of London in the reigns of Edward I. and II., was educated at Merton College, Oxford, became dean of St Paul's, was afterwards promoted to the see of London, and at last was made lord high chancellor of England. He wrote *Historia Anglica*, or a History of the British Affairs down to his own time; and *A Collection of the Statutes and Constitutions of the Church of St Paul.* The former, though it was seen by Leland, is not now extant; the latter is preserved in the library of that cathedral. He died at Stepney, July 24. 1313.

BALDRICK, a kind of girdle, richly ornamented, which in feudal times served to indicate the rank of the wearer. The term is sometimes applied also to the zodiac.

BALDWIN, THOMAS, a celebrated English prelate, was born of obscure parents at Exeter, where, in the early part of his life, he taught a grammar-school. After this he took orders, and was made archdeacon of Exeter; but he resigned that dignity, and became a Cistercian monk in the monastery of Ford in Devonshire, of which, in a few years, he was made abbot. In the year 1180 he was consecrated bishop of Worcester. In 1184 he was promoted to the see of Canterbury by Pope Lucius III., and by his successor Urban III. was

Baldwin ‖ Balen.

appointed legate for that diocese. He laid the foundation of a church and monastery in honour of Thomas à Becket at Hackington, near Canterbury, for secular priests; but being opposed by the monks of Canterbury and the pope, he was obliged to desist. Baldwin then laid the foundation of the archiepiscopal palace at Lambeth. In 1190 he crowned King Richard I. at Westminster, and soon after followed that prince to the Holy Land, where he died at the siege of Ptolemais or St Jean d'Acre. Giraldus Cambrensis, who accompanied him in this expedition, says he was of a mild disposition, and practised great abstinence. He wrote various tracts on religious subjects, which were collected and published by Bertrand Tissier in 1662.

BALDWIN, the name of nine counts of Flanders, the last of whom ascended the throne of Constantinople in 1204. There were also four kings of Jerusalem of this name, from 1100 to 1186, when the nephew of the last, then a child, was titular king until the capture of the city by Saladin in 1187. See CRUSADES.

BALE, JOHN, bishop of Ossory, in Ireland, was born at Cove, near Dunwich in Suffolk, in the year 1495. At twelve years of age he was entered in the monastery of Carmelites at Norwich, and thence sent some years afterwards to Jesus College, Oxford. He was educated a Roman Catholic, but was afterwards converted to the Protestant religion by Thomas Lord Wentworth. On the death of Lord Cromwell the favourite of Henry VIII., who had protected him from the persecutions of the Romish clergy, he was obliged to fly, and took refuge in Flanders, where he continued eight years. Soon after the accession of Edward VI. he was recalled; and being first presented to the living of Bishop's Stocke (Bishopstoke), in Hampshire, in 1552 he was nominated to the see of Ossory. During his residence in Ireland he was remarkably assiduous in propagating the Protestant doctrines; but with little success, and frequently at the hazard of his life. On the accession of Queen Mary the tide of opposition became so powerful that, to avoid assassination, he embarked for Holland; but was so unfortunate as to be first taken by a Dutch man-of-war, and robbed by the captain of all his effects; then forced by stress of weather into St Ives in Cornwall, where he was arrested on suspicion of treason. Having obtained his release, however, after a few days' confinement, the ship in which he had embarked anchored in Dover road, where he was again seized on a false accusation, but soon liberated. On his arrival in Holland he was kept prisoner for three weeks, but at length obtained his liberty on paying L.30. From Holland he travelled to Basil in Switzerland, where he continued till Queen Elizabeth ascended the throne. After his return to England he was in 1560 made prebendary of Canterbury; where he died in November 1563, in the sixty-eighth year of his age. He was the author of many works, the most noted of which is his collection of British Biography, entitled *Illustrium Majoris Britanniæ Scriptorum Catalogus, a Japheto sanctissimi Noah filio ad An. Dom.* 1559. This work was first published in quarto in 1548, and afterwards, with various additions, in folio, 1557–59. Ames and Herbert have given a long list of his other works; and Tanner has given a list of his manuscripts, with the names of the places where they are preserved.

BALEARIC ISLANDS. The appellation is commonly derived from *βαλλεῖν, jacere*, because the inhabitants were excellent slingers. They are two in number, the Major and Minor; hence the modern names. See MAJORCA and MINORCA.

BALECHOU, JEAN-JACQUES-NICOLAS, an eminent French engraver, born at Arles in 1715; died at Avignon in 1765. His works are distinguished by decision and vigour, but are sometimes hard in the details. His chef-d'œuvre is the portrait of the king of Poland.

BALEN, HENDRICK VAN, historical and portrait painter, was born at Antwerp in 1560. He was a disciple of Adam van Oort; but quitting that master, he pursued his studies at Rome, where he resided for a considerable time. He died in 1632. All the historical subjects painted by Van Balen have merit. His designs of the Deluge, of Moses Striking the Rock, and the Drowning of Pharaoh, are meritorious compositions. His Judgment of Paris is accounted a masterly performance; and the figure of Venus, in particular, is exceedingly admired. He was Van Dyk's first master.

Bales ‖ Balfour.

BALES, PETER, a famous caligraphist, and one of the first inventors of short-hand writing. He was born in 1547, and is described by Anthony Wood as a "most dexterous person in his profession, to the great wonder of scholars and others." We are also informed that "he spent several years in sciences among Oxonians, particularly, as it seems, in Gloucester Hall; but that study which he used for a diversion only, proved at length an employment of profit." He is mentioned for his skill in micrography in Hollingshed's Chronicle, anno 1575. "Hadrian Junius," says Evelyn, "speaking as a miracle of somebody who wrote the Apostles' Creed and the beginning of St John's Gospel within the compass of a farthing: what would he have said of our famous Peter Bales, who, in the year 1575, wrote the Lord's Prayer, the Creed, Decalogue, with two short prayers in Latin, his own name, motto, day of the month, year of the Lord, and reign of the queen, to whom he presented it at Hampton Court, all of it written within the circle of a single penny, inclosed in a ring and borders of gold, and covered with a crystal so accurately wrought as to be very plainly legible; to the great admiration of her Majesty, the whole privy-council, and several ambassadors then at court?" Bales was likewise very dexterous in imitating handwritings, and about 1576 was employed by Secretary Walsingham in certain political manœuvres. We find him at the head of a school near the Old Bailey, London, in 1590, in which year he published his *Writing Schoolmaster, in three parts.* In 1595 he had a great trial of skill in the Blackfriars with one Daniel Johnson, for a golden pen of L.20 value, and won it; and a contemporary author further relates that he had also the arms of caligraphy given him, which are azure, a pen or. Bales seems to have died about the year 1610.

BALEY, WALTER, physician in ordinary to Queen Elizabeth, was born at Portsham in Dorsetshire, in 1529, and died in 1592. Having taken his degrees in arts at Oxford, he practised physic; and in 1558 was proctor of the university. About this time he obtained a prebend of Wells, which he resigned in 1579. In 1561 he was appointed queen's professor of physic; in 1563 took his degree of M.D.; and afterwards became one of Her Majesty's physicians in ordinary. His works are, *A Discourse of certain Baths in the County of Warwick, near Newnham-Regis*, 1587, 8vo; *A Discourse of three kinds of Pepper in common use*, 1588, 8vo; *Brief Treatise of the Preservation of the Eyesight*, first printed in the reign of Elizabeth in 12mo, afterwards at Oxford in 1616, 1654, and 1673, 8vo; *Directions for Health, Natural and Artificial, with Medicines for all Diseases of the Eyes*, 1626, 4to.

BALFOUR, SIR JAMES, of Pittendreich, at one time lord president of the Supreme Court in Scotland, an intriguing and corrupt man of the stormy period of the sixteenth century. He was the author of a collection of the statutes entitled *The Practicks.* See SKENE, Sir John.

BALFOUR, *Sir James*, Bart., of Denmylne and Kinnaird, lord lyon king-at-arms in the reigns of Charles I. and II., was eminent as an annalist, a lawyer, and antiquary. He appears to have been an able and indefatigable collector of MSS., and left, besides his *Annales of Scotland*, sixteen treatises on genealogies and heraldry. Some of his works are preserved in the Advocates' Library at Edinburgh, together with his correspondence; from which rich collection

Balfour || Balguy.

Mr Haig published *Balfour's Annales of Scotland, from the zeire* 1057 *to* 1603, in 4 vols. 8vo.

BALFOUR, *Robert*, a learned Scotchman, born about the year 1550, who was for many years principal of the Guienne College at Bordeaux. His principal work is his Commentary on the Logic and Ethics of Aristotle (Burdig. 1616–20, 2 tom. 4to), which is described by Dr Irving (*Lives of the Scottish Writers*) as uniting vigour of intellect with great extent and variety of learning. Balfour was one of the most learned men of the time, and is spoken of by Dempster as the "phœnix of the age," the "stay of his countrymen," and the "glory of his nation."

BALFROOSH, a large commercial town of Persia, province of Mazanderan, on the river Bahbool, which is here crossed by a bridge of nine arches, about 12 miles distant from the southern shore of the Caspian Sea. It is built in a low, swampy, though rich country; and, from the deep and almost impassable roads which lead to it, seems not at all favourably situated for the seat of an extensive inland trade. It is, however, peopled entirely by merchants, mechanics, and their dependants; and is wholly indebted for its present size and importance to its commercial prosperity. The town is of a very peculiar structure and aspect. It is placed in the midst of a forest of tall trees, by which the buildings are so separated from one another, and so concealed, that except in the bazaars it has no appearance of a populous town. The streets are broad and neat, though generally unpaved; and they are kept in good order. No ruins are to be seen, as in other Persian towns; the houses are comfortable, in good repair, and roofed with tiles; and they are inclosed by substantial walls. According to Fraser, by whom it was visited in 1822, Balfroosh had a plain and simple air of plenty, ease, and comfort, attended with a bustle and show of business which is rarely to be seen in the Persian towns. There are no public buildings of any importance. The only places of interest are the bazaars, which extend fully a mile in length, and consist of substantially-built ranges of shops, covered with a roof of wood and tiles, and well stored with commodities. There are about ten principal caravanserais, several of which are attached to the bazaar, and are let as warehouses for goods; and from twenty to thirty medresses or colleges, the place being as much celebrated for learning as for commerce. At the time of Fraser's visit, it was said to contain 200,000 inhabitants; but this was probably an exaggeration; and since that time the plague and the cholera have committed great ravages, so that at present there may not be above 50,000. It is 20 miles W. of Sori. Long. 52. 42. E. Lat. 36. 37. N.

BALGUY, JOHN, an eminent English divine, born at Sheffield, in Yorkshire, in 1686. He was admitted of St John's College, Cambridge, in 1702; and having taken the degrees of B.A. and M.A., he soon after quitted the university. In 1711 he obtained a small living, and in 1729 was preferred to the vicarage of Northallerton, which he retained till his death in 1748. Besides sermons and various theological tracts, he published a philosophical work on the *Foundation of Moral Goodness*, written in answer to Dr Hutcheson's work on the *Origin of our Ideas of Beauty and Virtue*. Some of these pieces were collected by the author into one volume, and published with a dedication to Bishop Hoadley.

BALGUY, *Thomas*, D.D., son of the above, was born in 1716. After studying in St John's College, Cambridge, he was in 1746 presented to the rectory of North Stoke, in Lincolnshire. He afterwards became archdeacon of Salisbury, and of Winchester, in succession. He was offered the bishopric of Gloucester in 1781, but was prevented from accepting it by the declining state of his health. He was afterwards afflicted with blindness, and died at Winchester in January 1795. Besides sermons and charges, he was the author of a very able and well-known work, entitled *Divine Benevolence asserted, and vindicated from the Reflections of Ancient and Modern Sceptics*, 8vo, 1782.

Balharry || Balk.

BALHARRY, a town and fortress of Hindustan, situated on the W. side of the Haggry River, 187 miles N. from Seringapatam, and the capital of the British collectorate of the same name. The population, exclusive of military, is returned at 30,426. Elevation above the sea, 1600 feet. Lat. 15. 8. Long. 76. 59.

The district, of which the town is the principal place, contains an area of 13,056 square miles, with a population of 1,229,599, and forms a portion of the Balaghaut or tableland of the Deccan. Upon the partition of Tippoo Sultan's dominions, Balharry fell to the share of the nizam, by whom it was ceded to the British in 1800, in commutation of subsidy. From its centrical position Balharry is removed from the full force of either monsoon, and the climate is consequently characterized by aridity; the annual rain-fall ranging from 12 to 26 inches.

BALI, BALLY, or LITTLE JAVA, one of the Sunda Islands, in the Eastern Seas, separated from Java by the straits of the same name, which are three miles wide. It is a large island, being seventy-five miles in length by forty in breadth. A chain of mountains crosses the island in a direction E. and W., and terminates on the E. in the volcanic peak of Bali. The climate and soil are the same as in Java; it has mountains of proportionate height, several lakes, and streams well fitted for the purposes of irrigation. Rice is produced in great quantities, and two crops are raised in the year; while in the dry season the lands yield a crop of maize. The other productions are tobacco, oil, and salt; also cotton of an excellent quality. The inhabitants, though originally sprung from the same stock as those of Java, exceed them in stature and muscular power, as well as in activity and enterprising habits. "They have," says Sir Stamford Raffles, "a higher cast of spirit, independence, and manliness than belongs to any of their neighbours." They are also more moral, not being addicted to drunkenness or licentiousness, though they indulge in the practice of eating opium. Their favourite amusements are gambling and cock-fighting, to which they devote themselves with all the vehemence and energy of their character. They are inferior to their neighbours the Javanese in mechanical art and industry. Cotton is spun into yarn, and made into cloth by the women. Knives, and warlike instruments, such as matchlocks, are also manufactured. The principal exports are rice, edible birds' nests, coarse cloths, cotton yarn, salted eggs, &c. The imports are opium, betel nut, ivory, gold, and silver. The traffic in slaves was formerly great; all prisoners of war, insolvent debtors, and those who attempted to evade the laws against emigration, being reduced to the condition of slaves. The Hindu superstition is prevalent here. The island is divided into eight states, each under its own chief, subject to the Dutch. The total population is estimated at 800,000. (Raffles's *History of Java*; Temminck's *L'Inde Achipélagique*.)

BALIOL, or BALLIOL, SIR JOHN DE, founder of Baliol College in Oxford, was the son of Hugh Baliol, of Bernard's Castle, in the diocese of Durham, and very eminent on account of his power and riches. During the contests between Henry III. and his barons he firmly adhered to the king. In 1263 he began the foundation and endowment of Baliol College, which was afterwards perfected by his widow, Dervorgille. He died in 1269. His son, John Balliol, was the competitor with Bruce for the crown of Scotland.

BALIZE. See HONDURAS.

BALK, or BALKH (the ancient kingdom of Bactria), a province of Central Asia, now a dependency of the khanat of Bokhara, lying between Lat. 35. and 37. N., and Long. 63. and 69. E. The country of Balk is bounded by the Oxus on the N., by the great mountain range of the Hindu

Balk ‖ Ballad.

Khoh and Paropamisus on the S., by Badakshan on the E., and generally by sandy deserts on the W. It is said to extend 250 miles from E. to W., and from 100 to 120 miles from N to S. Towards the S. the country abounds in hills which branch out from the Hindu Khoh range. Here the soil is generally stony, though it has many well-watered valleys. The central portion of the country is level, fertile, and well watered, from the vicinity of the hills; while towards the N., near the stream of the Oxus, it is sandy and barren. The western part of the country of Balk, which borders on the desert, is of a similar nature; but in the E. there are mountainous tracts which are well watered, and occasionally fertile. The country descends very rapidly from the mountain range of Hindu Khoh, and towards the Oxus is of a lower level and of a much hotter climate than those parts of Afghanistan which lie to the S. of these mountains. Balk is inhabited by the Usbek-Tatars, Tanjiks, and Arabs. The total population is estimated at 1,000,000.

Balk, or *Balkh* (the ancient Bactra), formerly a great city, is now an immense and desolate mass of ruins, situated on the right bank of the Adirsiah, or Balk River, in a large and fertile plain, 1800 feet above the sea. These ruins consist chiefly of fallen mosques and decayed tombs built of sun-dried bricks, and occupy a space of about twenty miles in circuit. None of these ruins are of an age prior to Mahometanism. Balk is still called by the Asiatics "Mother of Cities," but its population, which once numbered some hundred thousands, now scarcely amounts to 2000. This city is said to have been built by Kaiomurs, the founder of the Persian monarchy; and here the archi-magus resided till the followers of Zoroaster were overcome by the khalifs. Zenghis Khan sacked the city, and butchered its inhabitants; and under the house of Timour it became a province of the Mogul empire. Balk formed the government of Aurungzebe in his youth, and was at last invaded by the great Nadir. Under the Dooranee monarchy it fell into the hands of the Afghans; and for the last twenty years it has been in the possession of the Khan of Bokhara. (See Burnes's *Travels in Bokhara.*)

BALKAN, the lofty mountain range that separates the waters of the Lower Danube from those that flow into the Archipelago. The name, however, has been extended to the whole mountain group that stretches from the Adriatic to the Euxine. The highest point of this range, Mount Orbelus, is 9000 feet above the sea. It rises to the W. of the town of Sophia.

BALLAD is a word frequently used as synonymous with *song;* but it properly denotes an historical song, or a song containing a narrative of adventures or exploits either serious or comic. It is one of the most ancient species of composition, and still constitutes a great portion of the literature of the more uncivilized tribes of mankind. Giovanni Finati, who supplies us with much information respecting the manners and customs of the East, has recorded the following anecdote of ballad-literature among the Benysackr Arabs, whom he found encamped near the shores of the Dead Sea. Their chief Ibn Fays, he states, "had strangers with him from Damascus, and feasted his guests so plentifully, that the wooden dish out of which we all fed had four iron handles to it, and required three persons to lift it and set it before us. Afterwards, a great earthen pan of grease was lighted as a lamp for the company, and Ibn Fays himself, and his brother, sung a sort of slow plaintive ballad to an instrument with one string, the purport of which was the tragic account of a battle against a neighbouring tribe, in which their own father perished."[1] The leader of this wandering horde might himself be the author, as well as the reciter, of the ballad which thus regaled his guests. Ballad.

Most of the nations of modern Europe have considerable collections of the ballads which delighted their forefathers; and in some countries the political influence of such compositions has been found to be very powerful. "Of these," says Dr Aikin, "the most copious source is party; and there has seldom been an occasion of political contest in countries permitting such freedoms, in which appeal has not been made to the popular feelings by means of comic and satirical ballads, often with great effect. The share that *Lillibulero* had in producing the Revolution in this country has been noticed by grave historians. In the war of the Fronde in France, ballads were a weapon as much employed as muskets, and those written for and against Cardinal Mazarin filled several volumes. The French give to these compositions the appropriate title of *Vaudeville*, implying their fitness to walk the streets; and indeed street-poetry in general belongs to the ballad class."[2] The Spaniards,[3] and other nations of the south, have preserved ample collections of their early ballads; but the affinity of our own nation and tongue with those of the northern tribes, renders their literary reliques an object of more particular interest. The various tribes of Scandinavians have generally been distinguished for their love of poetry. Many ancient reliques of Icelandic poetry are still preserved, and are regarded as very curious specimens of the literature of the different ages to which they belong; nor are the kindred nations of Sweden and Denmark without their early and recent poets, some of whom have attained to high reputation. Of the ballad-poetry of these northern nations, many remnants have descended to our times; and ample collections of Danish, Swedish, and even Feroese ballads have recently been published by respectable editors. "The songs mentioned by Tacitus in his account of the Germans," says Mr Jamieson, "those collected by the order of Charlemagne, and those which the Goths brought with them out of the East, are now not to be found; yet it is more than probable that much more of them is preserved, in however altered a form, than we are aware of; in the elder Northern and Teutonic romances, the Danish and Swedish, Scottish and English popular ballads, and those which are sung by old women and nurses, and hawked about at fairs, in Germany."[4] The same ingenious and well-informed writer has elsewhere expressed his conviction, that many of the traditionary ballads still current in this kingdom have been preserved in the north of England and the lowlands of Scotland, ever since the arrival of the Cimbri in Britain.[5] Many of our historical ballads may at all events be considered as the productions of a remote period; but it is not to be supposed that they have been transmitted from one generation to another without innumerable transformations. A great proportion of them have doubtless been preserved by oral tradition; and they seem in general to have undergone such changes as brought them nearer to the current speech of each successive generation; for, without this progressive adaptation, the lapse of a few centuries would have rendered them unintelligible to the great body of the people; nor is it usual for any combination of words to be retained in the memory without being understood. Thus, for example, we have reason to believe that the ballad of Sir Patrick Spence derives its origin from a very early age; but the variations to which it must gradually have been subjected, may easily

Ballad. be inferred from a comparison of the different copies which are now to be found.[1] A story may thus be preserved, when most of the original words have been changed. The close affinity between the old Danish and the old Scottish and English ballads has been noticed by various writers, by Pinkerton, Jamieson, Nyerup, Geijer, and Grimm:[2] their resemblance is to be traced in the general spirit and contrivance of the poems; while some of the Danish and Scottish ballads exhibit a remarkable coincidence in their particular stories. Whether these effects are to be imputed to so remote a cause as the emigration of the ancient Scandinavians, may however admit of much doubt and hesitation. Fiction moves from one region to another with very elastic steps, and in many instances it is impossible to trace her progress.

The earliest collector of Danish ballads was Anders Sörensön Vedel, chaplain to the king of Denmark, and an intimate friend of the celebrated astronomer Tycho Brahé. His publication bears the title of a hundred select Danish ballads, or *Et hundrede vduaalde Danske Viser*. Ribe, 1591, 8vo. It is now a very rare book, even in Denmark; but a copious account of it is given by Nyerup, in the last volume of the more recent collection of *Danske Viser*. After an interval of more than a century, another clergyman, Peder Syv, reprinted this collection of Vedel, and added an equal number of ballads. Kiöbenhavn, 1695, 8vo. But the most extensive collection appeared under the following title: *Udvalgte Danske Viser fra Middelalderen;* efter A. S. Vedels og P. Syvs trykte Udgaver, og efter haandskrevne Samlinger, udgivne paa ny af Abrahamson, Nyerup, og Rahbek. Kiöbenhavn, 1812–14, 5 bind. 8vo. This work is accompanied with notes and illustrations, and appears to us to possess no inconsiderable value. A similar collection of Swedish ballads was published by Geijer and Afzelius: *Svenska Folk-Visor fran Forntiden*, samlade och utgifne af Er. Gust. Geijer och Arv. Aug. Afzelius. Stockholm, 1814–16, 3 del. 8vo. These volumes are accompanied with music, printed in a quarto form. Of Feroese ballads there is a recent collection: *Færöiske Qvæder om Sigurd Fosnersbane og hans Æt*, med et Anhang: samlede og oversatte af Hans Christian Lyngbye, Sognepræst i Gjesing; med en Indledning af P. E. Müller, Dr. og Prof. i Theol. Randers, 1822, 8vo. Dr Müller, the author of the introduction, is a learned and able writer, well known as the author of more important works.

Debes mentions that, at their weddings, and at Christmas, the Feroese were accustomed to "recreate themselves with a plain dance, holding one another by the hand, and singing some old champion's ballad."[3] These islands were peopled in the ninth century by a colony of Norwegians.[4] The language of the people, as it appears in these ballads, is removed to a considerable distance from the Icelandic as well as the Danish. The plan of publishing a Feroese dictionary was formed about seventy years ago; and the English prospectus printed upon that occasion furnishes so curious and entertaining a specimen of the language, that we are tempted to insert it with all its peculiarities.

"*Subscription.*—We are minded after many years troublesome Collection to acquaint the World with the Tongue, used upon the Isles of Fero, a Dialect of the old noble Tongue in former Times written and spoken in Norway, Denmark, Island, Swede, and in a good Deal of the english Dominion. Now it appears for the world translated in Latin, Danish, and conferr'd with the islandsh Tongue.

"If we were men of Wealth, we would not forbear to Regard the Expenses of printing this Dictionary as a great Trifle, because it, very likely, not will exceed a good Volume in 4to; but we are poor-men. Nevertheless we hope to bring it forth by Way of Subscription, and for that Reason, We invite hereby our Neighbours, the brave and Reasonable Englishmen to Deal with us the Honour of bringing this Dialect out of the Darkness, wherein it lies, and let it see the Day-Liht. No-Body of our Countrymen, as we know, has thought this before. Ballast ‖ Ballet.

"Perhaps this moment in our Life, that has been the first in Time for this Purpose, will be the Last, and no body afterwards would attend it. The Price will be 2 pence a Sheet, and upon good Paper 3 pence.

"*N. Mohr. J. C. Svabo.*"

The two pages which follow are divided into columns, for the *Names of the Subscriptors* and the *Number of Exemplars;* but it appears that the well-meaning and painstaking creatures met with too little encouragement to proceed in their enterprise. The prospectus is without a date; but we learn from Müller and Nyerup that Svabo was employed in collecting Feroese ballads in the years 1781 and 1782. (D. I.)

BALLAST, any heavy matter, as stone, gravel, or iron, thrown into the hold of a ship, in order to make her sink a proper depth in the water, that she may be capable of carrying a sufficient quantity of sail without upsetting. To ballast a ship properly, the materials should be so disposed that she may be duly poised, and maintain a proper equilibrium on the water, without either being too *stiff* or too *crank*, which are conditions equally pernicious. Stiffness, in ballasting, is occasioned by disposing a great quantity of heavy ballast, as lead or iron, in the hold, which naturally places the centre of gravity very near the keel; and that being the centre about which the vibrations are made, the lower it is placed, the more violent will be the motion of rolling Crankness, on the other hand, is occasioned by having too little ballast, or by disposing the ship's lading so as to raise the centre of gravity too high, which also endangers the mast when it blows hard. For, when the masts are deflected from the perpendicular, they strain on the shrouds in the nature of a lever, which increases as the sine of their obliquity.

Ships are said to be *in ballast* when they have no other loading. Masters of vessels are obliged to declare the quantity of ballast they bear, and to unload it at certain places. They are prohibited unloading their ballast in havens, roadsteads, &c., the neglect of which prohibition has ruined many excellent ports.

BALLATER, a village of Aberdeenshire, on the River Dee, 42 miles from Aberdeen. It is much resorted to in the summer season, on account of the romantic scenery in the vicinity, and the fine medicinal wells at Pananich, about two miles distant.

BALLENDEN, John. See Bellenden.

BALLENSTEDT, a city in the duchy of Anhalt-Bernburg. It is situated in the Hartz Forest, in a most picturesque district, selected for a seat of the sovereign, whose castle is accommodated with the usual appendages of courtly residences. The city, besides the court, contains about 3800 inhabitants, who are very industrious in linen manufactures, gardening, &c.

BALLET (derived through the Italian *ballare*, from the

Ballina. Greek Βαλλίζειν, to dance) is a dramatic representation composed of dancing and pantomime guided by music.

The Greeks were the first who united the dance to their tragedies and comedies; not indeed as making part of those spectacles, but merely as an accessary.

The Romans, as usual, copied from the Greeks; but in the reign of Augustus they left their instructors far behind them. At that time a new species of entertainment was brought upon the stage, and carried to an astonishing degree of perfection. Nothing was then talked of but the wonderful performances of Bathyllus, Pylades, and Hylas, who were the first to introduce among the Romans what the French call the *ballet d'action*, in which the performer is both actor and dancer.

The enthusiasm excited among the Roman public by these celebrated *pantomimes* (*pantomimi*) was extraordinary. Pylades personified grave and tragic subjects, while Bathyllus excelled in the representation of the comic. Each had his school of disciples, and his host of partizans, whose eager rivalry often led to serious disturbances. The demoralizing effects of these exciting representations are severely noted by the great satirist Juvenal (vi. 63). These entertainments, though proscribed by some of the emperors, continued popular down to the fall of the empire. In the time of Augustus, only one actor appeared on the stage, representing singly the various parts in succession. About the end of the following century the number of performers was increased. No women took part in the public pantomimes till the last and worst period of the empire.

Buried with the other arts in the fall of the Roman empire, dancing remained uncultivated till about the fifteenth century, when ballets were revived in Italy at a magnificent entertainment given by a nobleman of Lombardy at Tortona, on account of the marriage of Galeas Duke of Milan with Isabella of Aragon. Every resource that poetry, music, dancing, and machinery could supply, was employed and exhausted on the occasion. The description given of so superb an entertainment excited the admiration of all Europe, and roused the emulation of several ingenious persons, who improved the hint by introducing amongst their countrymen a kind of spectacle equally pleasing and novel.

Female performers do not appear to have taken part in the various entertainments given at the opera in Paris till the 21st of January 1681, when the then dauphiness, the Princess of Conti, and some other ladies of the first distinction in the court of Louis XIV., performed a ballet in the opera called *Le Triomphe de l'Amour*. This additional attraction rendered the spectacle more lively than it ever had been at any other period; and it was received with so much applause, that on the 16th of May following, when the same opera was acted in Paris at the theatre of the Palais Royal, it was thought indispensable for its success to introduce female dancers. They have continued ever since to be the principal support of the opera.

A ballet perfect in all its parts, says Noverre, in his treatise on this subject, is a picture drawn from life, of the manners, dresses, ceremonies, and customs of all nations. It must therefore be a complete pantomime, and speak, as it were, through the eyes, to the very soul of the spectator. If it be deficient in point of expression, of situation, or of scenery, it degenerates into a spectacle equally flat and monotonous. (*Lettres sur les Arts Imitateurs, et sur la Danse en particulier*, 8vo. Paris, 1807.)

BALLINA, a seaport and market town of Ireland, county of Mayo, 18 miles N.N.E. of Castlebar. It is a neat clean place, pleasantly situated on the river Moy, which is here crossed by two bridges. Pop. in 1851, 4635. Ardnaree, on the opposite side of the Moy, is popularly included, making a total population of 6569. It has a parish and a Roman Catholic church, Baptist and Methodist chapels, a court-house, workhouse, hospital, dispensary, barracks, and several schools. The salmon fishery, and provision and fish curing, are important branches of its trade; and it has also breweries, flour mills, and manufactures of snuff and coarse linen. The amount of customs duty received in 1850 was L.5000. In 1798 Ballina was for a short time in the possession of the French under General Humbert.

Ballinahinch || Ballistic Pendulum.

BALLINAHINCH, a small town of Ireland, county of Down, seven miles W.N.W. of Downpatrick. It is much frequented in summer on account of a chalybeate spa about two miles N.W. of the town. Pop. in 1851, 1006.

BALLINASLOE, a town of Ireland, province of Connaught, 91 miles W.S.W. of Dublin. The River Suck, an affluent of the Shannon, divides it into two parts, the western being in the county of Galway and parish of Kilclooney, the eastern in the county of Roscommon and parish of Creagh. These are connected by a causeway across an island in the river and by two bridges. It is clean and well-built, and contains a handsome church, with a singular octagonal spire springing from scrolls. There are Roman Catholic and Methodist chapels, several public schools, district lunatic asylum, union workhouse, market-house, a savings-bank established in 1822, several flour mills, hat and coach factories, and breweries. Pop. in 1851, 6550. The great annual cattle fair, held from the 5th to the 9th of October, and for which Ballinasloe has long been celebrated, has latterly declined, as will be seen from the following table:—

	Sheep.			Horned Cattle.		
	Sold.	Unsold.	Total.	Sold.	Unsold.	Total.
1847	53,095	27,424	80,519	7,698	2,756	10,454
1848	57,287	9,758	67,045	7,297	865	8,162
1849	60,256	1,198	61,446	7,844	4,914	12,758
1850	51,668	2,404	54,072	9,395	6,400	15,795
1851	47,072	3,477	50,549	10,640	1,019	11,659

The number for sale in 1828 exceeded that of any other year since 1790, being 97,384 sheep and 11,513 horned cattle.

BALLINROBE, a small well-built town in Ireland, county of Mayo, situated on the Robe, 16 miles S.S.E. of Castlebar. It has a parish church, Roman Catholic chapel, several schools, and a union workhouse. Pop. in 1851, 2161.

BALLISTA, or Balista, a military engine used by the ancients for discharging darts, javelins, and stones. The name is derived from the Greek word *βάλλειν*, to *throw*. It would appear that the projectile force of these machines, in their several kinds, was derived from the torsion of ropes by means of a lever. Their power was very great, and indeed they may be said to have answered, in some degree, the purposes of modern artillery. The balista originally differed from the *catapulta*, which was used for discharging darts; but they are confounded by writers subsequent to the time of Julius Cæsar.

BALLISTEA, in *Antiquity*, songs accompanied by dancing, used on occasions of victory. Vopiscus has preserved a song of this kind sung in honour of Aurelian, who, in the Sarmatian war, was said to have killed forty-eight of the enemy in one day with his own hand. *Mille, mille, mille, mille, mille, mille decollavimus: Unus homo mille, mille, mille, mille decollavit; mille, mille, mille vivat, qui mille, mille occidit. Tantum vini habet nemo, quantum fudit sanguinis.* The same writer subjoins another popular song of the same kind: *Mille Francos, mille Sarmatas, semel occidimus; mille, mille, mille, mille, mille Persas quærimus.* The term is derived from the Greek *βάλλω*, I cast or toss, on account of the motions used in this dance, which consisted in elevating, swinging, and throwing round the hands. The *ballistea* were a kind of popular ballads, composed by poets of the lower class, with little regard to the laws of metre.

BALLISTIC PENDULUM, an ingenious machine, invented by Benjamin Robins, for ascertaining the velocity of

Ballistraria || Ballot.

military projectiles, and consequently the force of fired gunpowder It consists of a large block of wood, affixed to the end of a strong iron stem, having at the other end a cross steel axis, placed horizontally, about which the whole vibrates together like the pendulum of a clock. The machine being at rest, a piece of ordnance is pointed straight towards the wooden block or ball of this pendulum, and then discharged: in consequence of which the ball strikes, enters the block, and causes the pendulum to vibrate more or less according to the velocity of the projectile or the force of the blow; so that by observing the extent of the vibration, or the chord of the arc,—which is ascertained by means of a ribbon fixed to the lower extremity of the pendulum, and passed through a couple of steel edges something in the manner of a drawing pen,—the force of that blow becomes known, or the greatest velocity with which the block is moved out of its place, and consequently the velocity of the projectile which struck the blow and urged the pendulum. See Gunnery.

BALLISTRARIA, cruciform apertures in the walls of a stronghold, through which the cross-bowmen discharged their bolts. It also signified a projecting turret, otherwise called a bartizan, such as is commonly seen in the castles of the Border.

BALLOON. See Aeronautics.

Balloon, a kind of game somewhat resembling tennis, played in the open field, with a great ball of leather inflated with air, and driven to and fro with the strength of the arm.

Balloon, in the older chemistry, was the name for a spherical receiver used in distillation.

BALLOT (from the French *ballotte*, a little ball), a general expression for the practice of private voting, from its being usually accomplished by depositing a ball or ticket. Its most important signification in modern politics is when it is applied to the great question of the secret or public exercise of the suffrage in elections of members of the legislature. The *vindex tacitae libertatis*, as Cicero calls it—the giving effect to the exercise of opinion in such a manner as to defeat by secrecy the influence of other persons on him who has to exercise the function—has been sought after in many countries and times. In Greece the dikasts gave their verdict by ballot, according to arrangements varied from time to time. It was signified by a mark on a shell, or by the depositing of a ball or a stone, white or black according to the verdict; whence comes the proverbial reference to "a white stone" as connected with good fortune, and the expression "black-balling," which is sometimes even still practical as well as figurative. The Greeks, indeed, like the members of clubs and societies at the present day, had two methods of taking the vote—either by two balls and one box, or by two boxes and one ball. The well known ostracism was a species of condemnation by ballot, arising out of the old constitutional principle, that on questions of personal privilege—whether it were for conferring on the candidate what the ordinary citizen did not enjoy, or depriving him of his ordinary legal rights—the vote of a certain number of the citizens taken secretly was necessary. Of the ostracism as exercised in Athens, Mr Grote, who is a great champion of the ballot, gives an interesting vindication in his History of Greece, where he endeavours to show that, as a mere removal from the state without a forfeiture of property or position, or any other privation, it was the gentlest manner in which the republic could protect itself against those whose waxing power threatened a danger to the constitution, which, if not checked, might produce more disastrous effects, not only to the state, but to the aggrandizing citizen himself.

Among the Romans, just as we use the word ballot, *tabella* or *tabula*, a ticket, was employed to express the voting of the citizens or judges in comitia or courts of justice. In voting for a law there would be two tickets,—one inscribed V R. *uti rogas* or assent; the other A., the initial of *antiquo*—for the old law. When it was a case of election, the names of the candidates were written on the tabella, the voter putting a punctum or puncture opposite to the favoured name; and Cicero speaks of how many *puncta* a man will have in such a tribe, as we speak of the number of votes one will have in a ward. The tabellæ were cast into a cista, and the officers called *diribitores* are supposed to have been those who cast up the votes. The different laws from time to time establishing secret voting were called *Tabellariæ Leges*. Among these, the enactment most resembling the ballot in its modern acceptation, called the *Gabiana Lex*, for the election of magistrates, dates from about 140 years before Christ. Others are named the *Cassia Lex*, *Papinia Lex*, and *Cœlia Lex*.

Ballot.

Secret voting was a peculiarity of the Venetian senate, and the first shape in which the ballot was demanded in Britain was not for the purpose of elections, but of votes in parliament. In a work published after the Revolution, called *State Tracts, being a collection of several treatises relating to the Government, privately printed in the reign of King Charles II.*," a tract is reprinted, called "*The benefit of the Ballot, with the nature and use thereof;*" supposed to have been written by Andrew Marvell. Voting by ballot in the legislature was a frequent demand of the popular party in Scotland during the reign of Charles II., and in the revulsions against the court it was at one time carried out. Sir George Mackenzie mentions an instance of its use, where it was arranged that the lord clerk-register should hold a bag to receive the "billets" at the foot of the throne, and they should be then secretly examined and burned; "which form," he says, "was thereafter punctually observed: only the register having a rooted quarrel against Southesk, did mark his billet with a nip when he received it, and thereby discovered his vote." In this country secret voting is at the present day chiefly known in social clubs, where a small number generally have the power of ostracising any candidate for admission with whom they would dislike, for any private reason of their own, to associate. The election of officers and other acts of public or joint-stock bodies, are sometimes determined by private votes, as in the important instance of the proprietors of India stock. It is generally remarked that this attempt at secrecy is ineffective, and the votes of the respective stockholders are quite well known; but they do not themselves generally seek concealment.

In France, under the constitutional charter, secret voting existed in the chamber of deputies from 1840 to 1845, when it was abolished on a project of Duvergier de Hauranne accepted by M. Guizot, who thought the *scrutin secret* productive of abuse. No argument can be brought from the practice on this occasion, any more than from other instances of secret voting in the legislature, to bear on the question of secret voting in elections. The two things are quite distinct, and, according to British constitutional notions, antagonistic; for, while secrecy is demanded for the elector, on the ground that he is not and should not be responsible, the proceedings of the members of the legislature have been subjected to increasing publicity, on the ground that they are responsible to their constituents for the faithful performance of the trust reposed in them. Nor is there, perhaps, any sounder practical illustration of the question to be derived from the more extensive electoral applications of the vote by ballot in connection with the events which followed the revolution of 1848. In taking the very critical vote which justified the *coup d'état* of December 1851 and led to the establishment of the empire, it is known that fear of disturbance compelled Louis Napoleon to have recourse to secret voting, and that the effect was guarded both by a limitation of the vote to a simple yes or no to the question of the prolongation of the presidency, and by arrangements for taking the votes in small groups, which rendered concealment difficult.

Ballot.

The ballot is adopted in elections in several of the United States, and many arguments against it have been founded on its bad or ineffective operation there. It is said that the voter cannot preserve secrecy in presence of the popular coercion which renders it most necessary; that those to whom the secret arrangements are committed flagrantly betray their trust; and that the voters on either side of a contest are quite well known to the public at large. It must be remembered, however, that the characteristic defects of American elections are not those from which protection is sought in this country, nor are they of a kind for which the ballot is well adapted as a safeguard. There the evil to be obviated is the public and palpable coercion of the minority by the majority in the act of voting; in Britain it is the secret employment of individual influence away from the spot. The former influence may overbear, as it is said to do, the machinery for secrecy, but the latter has not the same means of accomplishing such an object.

In these references to experience may be traced some of the arguments which have at the present day been used in favour of and against secret voting. Among the arguments specifically brought forward against the proposal to adopt the system in England, it is said that the franchise is a trust which should be exercised with publicity, so that those interested may see how it is discharged. To this it is generally answered by the supporters of the ballot, that election is not a trust, but a function which each man must discharge according to what his own conscientious opinion, and not that of any other man, decides to be for the good of the community; and it is said that whoever ought to have any influence on an election, should enjoy it in the shape of a direct vote to be exercised by himself. Another argument used against the ballot has been, that it will be an enticement to falsehood, because voters will ever be induced to pledge themselves to particular sides, and under the protection of the ballot will falsify their pledges. The answer to this has generally been, that it may be a question whether it is a more immoral act to break a promise by voting according to conscientious opinion, or to vote against conscientious conviction in the coerced performance of a promise extracted by coercion. But it is generally maintained that secret voting will render such a balance of ethical difficulties unnecessary, because, as it will be impossible for the person who uses improper influence to be certain that it is efficacious, he will not have a sufficient prospect of success to tempt him to exercise it. Another argument against the propounders of secret voting has been, that were it the rule, any elector whose vote is desired by a person having an influence over him, would require to lead a life of hypocrisy, perpetually professing opinions which he does not hold, in order that the person exercising the influence may be led to believe that it has effectually entered into the nature of the voter and made him a partizan, whereas, under the system of open voting, he requires only to perform one act of hypocrisy—that of voting against his opinions—and is free to speak and act as he pleases in the other affairs of life. The answer generally given to this by the supporters of the ballot is, that the one effective act of hypocrisy—the voting wrong—is an act worth purchasing; but that it would not be worth the corrupter's while to buy a whole lifetime of hypocrisy, with the chance, if not the certainty, that the professed opinions would be discarded on the only occasions when the acting on them would be worth the purchase-money. It has been sometimes said that secrecy in voting is not practicable; but this is an argument rarely maintained as a serious objection to the ballot, for although the votes of a large portion of the community who are political partizans, and own their partizanship, must always be well known, there is no doubt that if it were sincerely set about, secrecy could be imparted to the votes of those who desire it.

Perhaps the argument which has proved the most influential against the ballot has been that, supposing it to be effective, it would to some extent deaden that open, candid system of party conflict, ranging the forces on every question palpably on either side, which is a main characteristic of British politics. In answer to this, it is generally admitted that the national characteristic has its merits, but it is said that the corruption of voters is a disease far outweighing them, the removal of which may be cheaply purchased by their sacrifice. It is generally admitted, however, that the progress of parliamentary morality during the past twenty years, and the gradual transition of electoral bribery from an act of gallant and justifiable expenditure, to a crime which men shrink from being charged with, has been removing or modifying a considerable portion of the disease for which the ballot has been sought as a remedy.

The ballot has occasioned frequent parliamentary discussions and divisions, yet it has never created any formidable conflict involving the fate of a party in parliament. After the accession of Lord Melbourne's government in 1835, it became in all Whig governments an open question, or one in which members of the government might take what side they pleased. It is one of those matters of which it is necessary, in a work like the present, to give some historical account, and at the same time to explain its existing position as a political question; and this has been done with an endeavour to avoid partizanship, and give a fair view of the arguments adopted by either side. (J. H. B.)

Ballston || Balm of Gilead.

BALLSTON, a town in the state of New York, celebrated for its spa.

BALLYBAY, a market and post town of Ireland, in the county of Monaghan, 86 miles from Dublin. Pop. in 1851, 1617, chiefly engaged in the linen manufacture.

BALLYCASTLE, a decayed seaport town of Ireland, county Antrim, situated on a bay opposite Rathlin island. The town is well-built, consisting of two parts, about a quarter of a mile asunder, and connected by a fine avenue. Upwards of L.150,000 were expended upon the harbour and pier, but the violence of the sea overthrew the pier and filled the harbour with sand, so that Ballycastle is now little more than a fishing village. Pop. in 1851, 1669.

BALLYMENA, a town of Ireland, county Antrim, on the Braid, an affluent of the Maine, two miles above their junction. It is 33 miles N.N.W. of Belfast, with which it is connected by railway. The town owes its prosperity chiefly to its linen trade, which gives employment to the greater part of the inhabitants. It has a parish church, several chapels and schools, a market-house, distillery, and several branch banks. Pop. in 1851, including Hanyville in the suburbs, 6493.

BALLYMONEY, a village of Ireland, county of Antrim, 140 miles N. of Dublin. Pop. in 1851, 2578.

BALLYSHANNON, a seaport and market town of Ireland, county of Donegal, situated on the Erne, at its influx into the bay of Donegal. Lat. 54. 30. N. Long. 8. 11. W. The river is here crossed by a bridge of 14 arches, which connects the town with the suburb of Purt. Below the bridge the river forms a beautiful cascade 150 yards wide, with a fall at low-water of 16 feet. The harbour is a small creek of Donegal Bay, about 600 yards long, and 350 yards broad, and is only accessible to small vessels. The town contains a church, several chapels, a bank, market-house, barracks, and a union workhouse. Previous to the Union, Ballyshannon returned two members to the Irish Parliament. Pop. in 1851, 3697.

BALM OF GILEAD. Among the more precious substances obtained from plants, applied as curative of wounds by the ruder inhabitants of the Eastern climates, the balm of Gilead, or balsam of Mecca, has been eminently distinguished during many ages. But although the balm of Gilead is well known from several scriptural allusions, and highly esteemed, it is only of secondary quality to the bal-

Balm of Gilead.

sam of Mecca, for which it is frequently substituted; and illustrations of its nature and properties must chiefly be derived from the latter. This balsam is a resinous matter, exuding, like ordinary resin, from incisions in the bark of two different vegetables; at least there are apparently two, though the distinction is not well characterized or described by naturalists. The plant producing the balsam of Mecca was first ascertained by Forskal to belong to the genus *Amyris*. He transmitted one or two specimens to Linnæus, who has characterized it as the "*Amyris Opobalsamum*, leaves pinnate, with sessile leaflets, a native of Arabia;" while he characterizes the other as "*Amyris Gileadensis*, leaves ternate, very entire peduncles, one flowered lateral, a native of Abyssinia." This plant grows to the height of fourteen feet, flourishing in a hot climate, and in a stony barren soil. In general it is lower; and Mr Bruce describes a specimen five feet and a half in height, and five inches across the stem where thickest. The wood is white, light, and of open texture, covered with a smooth bark, reddish or bluish white, resembling that of a healthy standard cherry tree, green within, and emitting a very fragrant odour; that of the branches, which are very flexible and resinous, being equally agreeable. The leaves, which are evergreen and scanty, bear some resemblance to those of rue; and the flowers, which are leguminous and of a purplish colour, resemble those of the acacia. The fruit consists of small pointed ovoidal berries, containing a yellowish fluid similar to honey, of a bitterish taste, and exhaling a pleasant perfume, approaching the odour of balm.

The balsam flows from incisions in the tree, which are made with an axe, in July, August, and the beginning of September, when the circulation of the sap is in the greatest activity; and it is received into a small earthen bottle. The total exudation is usually but three or four drops in a day, nor does the most productive tree afford above sixty. Its scarcity, therefore, and the difficulty of procuring it, have no inconsiderable effect in enhancing its value. The odour is at first strong and pungent, occasioning a sensation like that of volatile salts rashly inhaled. Its intensity is proportioned to its freshness and the care it receives; for if neglected and exposed to the influence of the air, the fragrance entirely decays. It is also of a rough, acrid, pungent taste. Originally the balsam is of a light yellow colour, somewhat turbid, and of a whitish cast, which is supposed to arise from the globules of air absorbed along with it; and it dissolves readily in water. It then acquires greater consistence, resembling honey, and becomes pellucid; and after the lapse of some years grows of deeper yellow, or gold colour, when it is very tenacious, and may be drawn out in threads. It is difficult, however, to obtain the balsam in a state of purity; for several different substances are employed in its adulteration, to detect which various experiments are resorted to. If dropped into a glass of clean water, it falls to the bottom without rising again to the surface; or if it remain still on the surface, like oil in a drop, it is certainly adulterated. If, on the contrary, it spreads on the surface of the water, diffusing itself in a thin pellicle, scarcely visible to the eye, and capable of being collected with a thread or a feather, it is the pure and natural product. In this state it will coagulate like milk, but not if otherwise. If pure, it collects in a globule when dropped on hot iron; if adulterated, it runs and spreads itself all around. The different substances used in the adulteration of this balsam are honey, wax, oil of sesamum, turpentine, and ostrich fat. Sweetness of taste betrays the honey, and a turbid appearance the presence of wax. Adulteration with oil is detected by its yielding a darker and grosser flame than that which issues from the genuine balsam when dropped on burning coals. When the consistency becomes too great, which seems a consequence of age and long preservation, fluidity is restored by the simple application of heat.

Besides the balsam now described, which is the purest and most valuable kind, and is called Opobalsamum, other two of inferior quality are obtained from the balessan, the name by which the plant is known in the East: first, Carpobalsamum, which is prepared by expression from the fruit when it has attained maturity, and which, if good, should be ponderous, of a pungent taste and balsamic odour; secondly, Xylobalsamum, which is elaborated from a decoction of the twigs.

Balm of Gilead.

Prosper Alpinus, one of the older naturalists, ascribes many properties to the balsam of Mecca, esteemed the most precious of all that bear the appellation of balsam, and in ordinary description considered as synonymous with the balm of Gilead; and the modern Arabs, Turks, and Egyptians, entertain great confidence in its efficacy. Hasselquist says it is useful as a stomachic in doses of three grains. It is also taken for complaints in the breast, in fevers, and in rheumatism. Its repute as an antiseptic is very great; and by the Egyptians it is esteemed an effectual antidote against the plague. The balsam of Mecca, however, is principally used as a cosmetic by the Eastern females of rank.

The balm of Gilead has been celebrated from a very remote antiquity. We have the testimony of Moses that it was an article of commerce in the earlier periods of Jewish history; for at the time Joseph was confined by his brethren in a pit, and during their deliberations on his fate, it is said, "And they sat down to eat bread,—and they lifted up their eyes and looked, and behold a company of Ishmaelites came from Gilead, with their camels bearing spicery, and *balm*, and myrrh, going to carry it down to Egypt." Jeremiah particularly alludes to the virtues of the *balm in Gilead*. Josephus, however, does not carry the knowledge of it so high; for he observes, that the Queen of Sheba brought the balm of Gilead as a present to Solomon. The ancients who were contemporary with Josephus, seem to have regarded Judea as exclusively possessed of this product. Pliny remarks,—"but to all other odours whatsoever is to be preferred that balsam which is produced in no other part of the world than the land of Judea, and there in two gardens only, both belonging to the king, one not exceeding twenty acres in size, and the second still smaller." Strabo, however, in the opinion of Mr Bruce, ascertained the real spot where the balsam originated, in ascribing it to that country over or near to which the Queen of Sheba reigned. "Near to to this," he says, "is the most favoured land of the Sabæans and they are a very great people. Frankincense, myrrh and cinnamon, grow among them, and on the coast that is about Saba, the balsam also." Whence Mr Bruce observes that "among the myrrh-trees behind Asab, all along the coast to the Straits of Babelmandel, is its native country. It grows to a tree above fourteen feet high, spontaneously and without culture, like the myrrh, the coffee, and the frankincense tree; they are all equally the wood of the country, and occasionally cut down for fuel." Diodorus Siculus likewise affirms that this balsam grew in a valley of Arabia Felix. But Mr Bruce, who investigated the subject with considerable care, supposes that it was towards the era of Pliny that it received its name of *Balsamum Judaicum*, or balm of Gilead, and thence became an article of commerce and fiscal revenue, which might probably operate as a discouragement to bringing it from Arabia; as also that it might be prohibited as contraband. Some centuries later than the time of those ancient authors, we see that it was known in Arabia, and perhaps in the place now most celebrated for it. In the travels of Ali Bey it is stated that there is no balsam made at Mecca; that, on the contrary, it is very scarce, and is obtained principally in the territory of Medina; and also that it was called *belsan*. As the repute of the balsam of Mecca rose, the balm of Gilead disappeared; though in the era of Galen, who flourished in the second century, and travelled into Syria and Palestine purposely to obtain a knowledge

Balmerino || Balnearii.

of this substance, it grew in Jericho, and many other parts of the Holy Land. The cause of its total decay has been ascribed, not without reason, to the royal attention being withdrawn from it by the distractions of the country. In more recent times its naturalization seems to have been attempted in Egypt; but apparently without success.

Notwithstanding the celebrity of this plant, Mr Bruce denies that it had ever been seen by the ancients, by whom he probably means the Romans, as their descriptions are so various and discordant. Prosper Alpinus, who lived in the sixteenth century, does not seem to know the real class to which it belongs; and even more recently M. Duplessy is apparently not aware of its having been figured by Bruce, and still later by Dr Woodville. Such uncertainties of old excited a violent dispute between the inhabitants of Rome and Venice whether the drug used in medicinal compounds was truly the balm of Gilead; and the point being referred to the pope, his holiness directed that information should be obtained from Egypt, in consequence of which he decided in favour of the Venetians.

Several other balsamic plants of the same genus are enumerated by botanists, each exhibiting some peculiarity. J.G.D.

BALMERINO, a village and parish of Scotland, county of Fife, situated on the Tay, 8 miles N.W. of St Andrews. Pop. in 1851, 945. It has the ruins of an abbey founded in 1229, by Emergarde, mother of Alexander II.

BALMEZ, Jayme Lucien, a Spanish ecclesiastic, eminent as a political writer and a philosopher, was born at Vich in Catalonia, on the 28th August 1810. He is the author of several able works, of which that entitled *El Protestantismo Comparado con el Catolicismo en sus relaciones con la Civilisacion Europea*, is the one on which his reputation chiefly rests. It has been translated into French, German, and English. This gifted and amiable man died at Vich, on the 9th July 1848.

BALMORAL CASTLE, a residence of Her Majesty Queen Victoria, on the right bank of the River Dee, about 9 miles above Ballater, and 50 miles from Aberdeen. The building, which is of the Scotch baronial style of architecture, modified in some of its details, is larger and finer than the old castle which it replaced. The property consists of about 10,000 acres.

BALNAVES, Henry, a Scottish Protestant, born at Kirkcaldy in Fife, in the reign of James V., and educated at the university of St Andrews. He afterwards studied in France; and returning to Scotland, he entered into the family of the Earl of Arran, who at that time was regent: but, in the year 1542, the earl dismissed him for embracing the Protestant religion. In 1564 he joined (says Mackenzie) the murderers of Cardinal Beaton; for which he was declared a traitor, and excommunicated. Whilst that party were besieged in the castle of St Andrews, they sent Balnaves to England, who returned with a considerable supply of money and provisions; but being at last obliged to surrender to the French, he was sent with the rest of the garrison a prisoner to France. During his confinement at Rouen he wrote the work entitled *Confession of Faith;* but it was not published till 1584, five years after his death. He returned to Scotland about the year 1559, and having joined the Congregation, was appointed one of the commissioners to treat with the Duke of Norfolk on the part of Queen Elizabeth. In 1563 he was made one of the Lords of Session, and appointed by the General Assembly, with other learned men, to revise the *Book of Discipline.* Knox, his contemporary and fellow-labourer, gives him the character of a very learned and pious man. Balnaves died at Edinburgh in the year 1579.

BALNEARII Servi, in *Roman Antiquity*, servants or attendants belonging to the baths. Some were appointed to heat them, called *fornacatores;* others were denominated *capsarii,* who kept the clothes of those that went into them; others *aliptæ* and *unctores*, whose care it was to pull out the hairs and anoint and perfume the body.

Balognes || Baltic Sea.

BALOGNES. See Valonges.

BALSAM, the resinous juice of a tree or shrub; the true balsams being distinguished from the spurious ones, or turpentines, by containing benzoic or an analogous acid as one of their essential ingredients, in addition to the volatile oil and resin of which alone the turpentines consist. The true balsams known in commerce are five in number, viz., the balsam of Peru, yielded by the *Myrospermum Peruiferum;* the balsam of Tolu, procured from the *M. Toluiferum;* benzoin, the produce of styrax benzoin; storax, from the *Storax officinalis;* and liquid amber, from *Liquid-ambar styraciflua.* Balsams are used in medicine in certain diseased states of the mucous membranes, and are hence frequently prescribed in cough mixtures, and during recovery from certain inflammatory and diseased conditions of the mucous surfaces of the stomach and bowels, &c. Formerly balsamic preparations were much used in surgery for dressing wounds, sores, &c., but are almost completely exploded in modern practice in this country. Balsams are used also in the manufacture of sealing-wax, pastils, &c.; and the incense burnt in Roman Catholic chapels owes its peculiar perfume chiefly to the presence of benzoin. Canadian balsam, balsam of copaiba, balm of Gilead, &c., though commonly styled balsams, are not so, properly speaking, since they contain no benzoic acid.

BALSAMINEÆ, a natural order of plants. See Botany.

BALSAMODENDRON, a genus of plants belonging to the natural order of Amyrideæ. The *B. Myrrha* produces that gum-resin which is said also to be afforded by *B. Katof.* See Botany.

BALSOVER. See Bolsover.

BALTA, the capital of the circle of the same name, in the Russian government of Podolia. It stands on the Kodima, near its junction with the Bug, and carries on a trade in corn by that river. Population, including suburbs, about 10,000. Long. 29. 44. E. Lat. 47. 56. N.

BALTIC SEA. The denomination of the Baltic, applied to the inland sea which forms the subject of this article, is first found in the work entitled *Chorographia Scandinaviæ,* by Adam of Bremen, who was canon of that city at the close of the eleventh century. The etymology of the name has given rise to many conjectures. The Swedes derive it from the Scandinavian word *baelt,* a girdle, because of its peculiar form; the Prussians, from the Sclavonian or Lettonian word *balt,* white, from its being frozen part of the year, or from *Baltus,* one of their kings; while by others it is derived from *Baltea,* the name of an island mentioned by Pytheas, a merchant of Marseilles, who, in the second or third century before the Christian era, is supposed to have sailed as far north as this sea. In the countries which bound it, its ancient name was *Variatzkoïe Morè,* or the Sea of Variaghi; by the modern Russians it is called *Baltiskoè Morè;* and by the Swedes, Danes, and Germans, the *East Sea.*

Extent of the Baltic.

The Baltic is inclosed by Sweden, Russia, Prussia, Mecklenburg, and Denmark; and it communicates with the North Sea by the Skager-Rack, Cattegat, Sound, and Great and Little Belts. From Swinemünde in the S., to Tornea in the N., its length is 770 geographical miles; and its width from Karlscrona to Memel is not less than 180 miles. Its whole area, including the Gulf of Bothnia, is about 125,000 geographical square miles. It runs first in an easterly direction as far as Memel, a distance of 300 miles, and then northwards as far as Lat. 59. 21. N., a distance of 350 miles, at which point it separates into two great gulfs. One of these, the Gulf of Finland, runs nearly due E.; the other, the Gulf of Bothnia, almost N. The Gulf of Bothnia is 400 miles in length, with an average breadth of 120 miles, but where narrowest it does not exceed 40 miles.

Baltic Sea. The archipelago of Aland lies at its entrance. The Gulf of Finland is 200 miles in length, with a mean breadth of 60 or 70 miles. Numerous rocky islands and reefs, many of them level with the water, render the navigation of this sea extremely dangerous.

Depth of the Baltic. The greatest depth of the Baltic rarely exceeds 100 fathoms. On the western side it is not more than 15 fathoms; and, in general, it is only from 8 to 10 fathoms. On the S. it nowhere exceeds 50 fathoms. The Gulf of Finland suddenly shallows from 50 or 60 fathoms to 5, or even less. The average depth of the Gulf of Bothnia is not greater than that of the rest of the sea.

Level of its waters. It has long been a generally received opinion that the waters of the Baltic are gradually diminishing. Celsius, a learned Swede, who flourished towards the middle of last century, advances this hypothesis; and, from observations made on the coasts of the Baltic, he estimated the diminution at 45 inches in a hundred years. This hypothesis was supported by Linnæus, who founded on it a theory of the earth. M. Otto, in his physical observations on this sea, has suggested another theory to account for its apparent decrease. He supposes that, instead of really subsiding, it may be only shifting its position, and gaining in one quarter what it loses in another; and this he ascribes to the large and rapid rivers, which carry along with them an immense quantity of earth and sand, by which the beds at their mouths are raised, and their banks extend towards the sea. The views of Celsius have been confirmed by the observations of Von Buch, who also discovered at several places on the western shores of Scandinavia, and at considerable elevations, deposits of sand and mud containing numerous marine shells of species still existing in the neighbouring ocean. Mr Lyell at first entertained doubts of these phenomena; but on subsequent inspection he was led to concur in the opinion of Von Buch. Mr Lyell found the marks which were cut in the rocks at water-line some years previous to his visit, to be actually several inches above the level of the Baltic. From these observations, that eminent geologist concludes, that in several parts of Sweden a gradual elevation of the land is taking place. (Lyell's *Principles of Geology.*) The great quantity of sand and mud carried down by the rivers has considerably raised the bottom of this sea, and affected its navigation, so that the mouths of rivers formerly navigable are now inaccessible.

Tides. In the Baltic, the tides are scarcely, if at all, perceptible. There are sensible tides in the Skager-Rack; but these begin to diminish in the Cattegat, and are very trifling in the Sound and Belts. There are, however, irregular variations in the level of the waters of the Baltic which bear some resemblance to tides. These elevations generally occur in autumn, when the weather threatens rain; and they last sometimes a few days, sometimes several weeks. The maximum rise is three feet and a half, and the low shores are occasionally inundated. They also render brackish the fresh-water lakes which communicate with the sea. In the Gulf of Bothnia, the subsidence of the waters is usually succeeded by north winds; whereas, near Stockholm, these winds usually follow their rise. M. Kraft, formerly professor of experimental philosophy in the Imperial Academy of Sciences at Petersburg, in his treatise on the inundations of the Neva at the autumnal equinox, observes, that three or four days before or after the full or new moon, a violent N.W. wind drives the waters of the Northern Ocean, during the influx of the tide, into the Baltic, and is accompanied or immediately succeeded by a south wind in that sea and the Gulf of Finland. By Schultens, a learned Swede, who paid particular attention to the physical geography of the Baltic, the irregular elevations of this sea are attributed to the state of the atmosphere. He had observed that when the waters were about to rise the barometer fell, and that when they were about to fall it rose. Hence he inferred that the unequal pressure of the atmosphere on different portions of the water deranged the level of the waters. The difference between the greatest and the least rise of the barometer in the northern parts of Europe is two and a half inches, which answers to three and a half feet of water, or the difference of the elevation of the waters at their extremes. Baltic Sea.

Superior and inferior currents. In the Sound there are superior and inferior currents. These were first observed by some Englishmen, who, being in a boat in the middle of the channel, found that they drifted towards the Cattegat; but having let down a loaded bucket to the depth of four or five fathoms, the boat became stationary; and when the bucket was sunk deeper, the boat drifted against the superficial current. The general currents of the Baltic are strong, and evidently occasioned by the vast number of rivers and streams that pour their waters into it, many of which, especially towards the north, rise thrice in the course of the year. At the northern extremity of the Island of Bornholm, a violent agitation of the waters, or kind of whirlpool, called by the Swedes *malt-quern*, or the grinding-mill, is occasioned by the current rushing over a circular cluster of sunken rocks. The waves of the Baltic are short and broken, in consequence of sudden changes of wind, irregular depths, and strong currents.

Saltness. The waters of this sea are not nearly so salt as those of the ocean; and when the wind blows strong from the north they become so fresh as to be fit for drinking or cooking meat. The degree of their saltness varies in different parts, and even in the same parts, according to the season or wind. According to Bergman, in his *Physical Geography*, the waters near the south coast of Norway, at the entrance of the Skager-Rack, contain from $\frac{1}{10}$th to $\frac{1}{7}$th part of their weight of salt; in the Cattegat $\frac{1}{12}$th; in the Baltic $\frac{1}{16}$th; and in the Gulf of Bothnia from $\frac{1}{40}$th to $\frac{1}{60}$th. The S.W. and W. winds augment the saltness, by introducing the waters of the ocean. In the summer it requires 300 tons of the water of the Gulf of Bothnia to produce one ton of salt, but in the winter only 50 tons. This difference is caused by congelation, and by the diminished flow of fresh water.

Analysis of its waters. The analysis of three pounds of water taken up from the British Sea, on the coast of East Friesland, and the same quantity from near Rostock in the Baltic, gave

	British Sea.	Baltic.
Muriate of soda	522	263
Muriate of magnesia	198½	111
Sulphate of lime	23	12
Sulphate of soda	1½	1
Residue	1½	1
	746½	388

The following are the results of some experiments made by Dr Thomson on the specific gravity of the water in the Firth of Forth, the Baltic off Tunaberg, the Sound, and off the Skaw Point; and also on the comparative weight of salt obtained from 1000 grains of each of the waters evaporated.

	Specific gravity.	Weight of salt.
Water of the Firth of Forth	1·02900	36·6
Baltic off Tunaberg	1·00476	7·4
Sound	1·00701	11·2
Skaw	1·02037	32·0

In the salt obtained from the water off the Skaw, he found

Muriate of soda	55·7
Sulphate of magnesia	25·0
Muriate of magnesia	19·3
	100·0

Wilcke ascertained that the specific gravity of the water of the Baltic was much influenced by the wind. When the wind was at

East, it was	1·0039
West	1·0067
North-west	1·0098
Storm at West	1·0118

Baltic Sea. Temperature.

There is great difference in the temperature in different parts of the Baltic. The general temperature of the Gulf of Bothnia in July is from 48° to 56°, but it is sometimes heated to 70°; the medium of the thermometer throughout the year at Uleoborg is 29°, and at Stockholm 42⅘°. Near the land in the Gulf of Bothnia the temperature of the atmosphere in the month of July was observed to be 68°, while the temperature of the surface of the water was 65°; and in October the temperatures of both were respectively 39° and 46°. In the Sound, the temperature of the atmosphere in the month of August was 70°; on the surface of the water 68°; and at three fathoms 66°. On the 10th of October 1813, Dr Thomson found the temperature of the Sound to be 54°. The Skager-Rack and Gulf of Norway are open to navigation all the winter, whereas several portions of the Baltic are covered with ice in a very moderate degree of cold; and generally the bays and channels are encumbered with ice at the latter end of December. The waters towards the heads of the Gulfs of Bothnia and Finland are first frozen; and the ice being conveyed by the currents to the south, the masses of it are united by the increasing cold into vast fields, which become stationary on the west towards Stockholm, and in the east towards the islands of Dagœ and Œsel. In the southern parts of the sea the ice begins to break up in April, but the Gulfs of Bothnia and Finland often continue closed till May. The rigour of the climate in the Baltic is supposed to be considerably diminished by the clearing of the forests and the progress of cultivation; at least the frosts during the fourteenth and fifteenth centuries appear in their intensity and long continuance to have exceeded those of the severest seasons in more recent times.

The winds are extremely variable in the Baltic, but they blow most commonly from the E. in the spring, and from the W. in autumn. Calms are seldom experienced except in the middle of summer.

Fisheries.

There is historical evidence that the herring fishery was a branch of national industry in the Sound as early as the year 1168;[1] and in 1389, according to Philip de Mezières, such vast shoals of herrings crowded into the Sound, that 40,000 boats, with from six to ten men each, were employed in the fishery, besides 900 large vessels, in which the herrings were salted. This important branch of industry, however, no longer exists. Salmon ascend the rivers from April to June, according as they are free from ice. On the S. they abound most in the Oder, Vistula, Düna, and Narrowa; on the N., in the Motala, Dalecarlia, Ulea, Kemi, Tornea, and Keymen. Salmon-trout is taken in some bays of the Baltic. In the middle of the River Kemi is a small island where an annual salmon fair is held.

Whales very rarely enter the Baltic. The common porpesse is the only one of the lesser species of cetaceous animals that lives habitually in this sea; and at Middlefahrt, in Funen, is a company which enjoys the exclusive privilege of taking it. There are two varieties of the common seal, which are hunted for their oil in March and April by the peasants of the Isle of Gottland, and of the islands in the Gulfs of Bothnia and Finland.

The trade of the Baltic is of great extent and importance. In 1852, 17,563 ships passed up and down the Sound, of which 3902 were British vessels. The internal trade is also very considerable. The exports consist of the various productions of the countries on its coasts, and include corn, timber, pitch and tar, hemp, flax, tallow, hides, linseed, bristles, wool, &c. Its imports are colonial products, manufactured goods, dry stuffs, wines, salt, coal, &c. The most important ports are St Petersburg, Riga, Königsberg, Danzig, Swinemünde, Lübeck, Copenhagen, Karlscrona, and Stockholm. By means of numerous large rivers and canals a considerable trade is carried on with the interior. (See Thomson's *Travels in Sweden; Tableau de la Mer Baltique*, par Catteau; *Tableau des Etats Danois*, par Catteau.)

Baltimore.

BALTIMORE, a decayed town of Ireland, county of Cork, on a headland projecting into the sea. Previous to the Union it returned two members to the Irish parliament. It has a good harbour; but the population in 1851 was only 189. N. Lat. 51. 29. W. Long. 9. 20.

BALTIMORE, in Maryland, one of the largest and most flourishing cities in the United States of North America, is situated on the north side of the Patapsco River or Bay, 14 miles above its entrance into the Chesapeake, 37 miles N.E. of Washington, and 100 S.W. of Philadelphia; Lat. 39. 17. N. Long. 76. 36. W. The natural advantages of this position were long overlooked by the settlers in the vicinity of the Chesapeake, and it was only in 1729 that they directed their attention to this place, and laid out a plan of the town. At this time a part of it was under cultivation as a farm, but all the rest was a wilderness. For some years its growth was by no means rapid, as it had to contend with all the obstacles that could be thrown in its way by the jealousy of older rivals. From an authentic sketch of Baltimore made in the year 1752, it appears that it then contained about 25 houses, only four of which were built of brick, the rest being of a more primitive structure. In 1768 it became the county town; and in 1775, according to a census then taken, it contained 564 houses, and 5934 inhabitants. From this time it rose rapidly into importance, and in 1780 became a port of entry, when a custom-house was opened. Previous to this all vessels trading to and from the port had to be entered, cleared, and registered at Annapolis. In December 1796 it obtained an act of incorporation. By the census of 1850 Baltimore contained 169,012 inhabitants, of whom 141,441 were whites, 24,625 free coloured, and 2946 slaves.

The city is pleasantly situated on slightly undulating ground, and extends about 4½ miles from E. to W., and 3½ from N. to S., covering an area of 10,000 acres. It is divided into two nearly equal parts by a rapid stream called Jones's Falls, crossed by a number of bridges. The division east of the falls is nominally subdivided into two parts—Fell's Point and Old Town. The former, the most easterly part of the town, is the principal resort of seamen, and is the place where the shipbuilding and manufactures are principally carried on. The Old Town lies to the N. and W. of this, and is principally inhabited by mechanics and labourers. The portion west of the Falls is likewise divided into two parts, the city proper and Spring Garden. The former is the centre of trade, and the residence of the more wealthy inhabitants; while the latter, which is the extreme south-western quarter, and the lowest and most unhealthy portion of the city, is inhabited by the poorer classes. Baltimore contains upwards of 100 churches, 3 universities, 4 colleges, about 50 grammar schools and academies, numerous common schools; an infirmary, several hospitals, orphan asylums, dispensaries, &c.; two theatres, a circus, a museum, and many beautiful and commodious public buildings. The city hall is a plain three-storied building, with a portico of four massive pillars. The court-house, a large and commodious edifice constructed of marble and brick, is 145 feet long, 65 wide, and two stories high. It is adorned with several Tuscan columns, and the whole is surmounted by a cupola of an imposing appearance. The state penitentiary consists of three large buildings, besides workshops, &c., and, with its gardens and walks, occupies an area of

[1] "In the year 1238 the inhabitants of Gothia (Sweden) and Frise were prevented, by their fear of the Tartars, from sending as usual their ships to the herring fishing on the coast of England; and as there was no exportation, 40 or 50 of these fish were sold for a shilling. (Matthew Paris, p. 396.) It is whimsical enough that the orders of Mogul Khan, who reigned on the borders of China, should have lowered the price of herrings in the English market." (Gibbon's *Roman Empire*, vol. xi. p. 422.)

Baltimore.

four acres, surrounded by a stone wall 20 feet high. The Merchants' Exchange is a spacious building 225 feet long by 141 feet wide, and contains a reading-room, the custom-house, a bank, telegraphic offices, &c. The room in which the merchants' meetings are held is 53 feet square, and is lighted by a dome 115 feet above the street. On its east and west sides are colonnades, the columns of which are each a single block of fine Italian marble. Baltimore has also several splendid monuments, which have acquired for it the name of "the Monumental City." The largest of these, erected to the memory of Washington, stands on an eminence of 150 feet, and has, with its base, an altitude of 200 feet. It is built of white marble: the base is 50 feet square, and 20 feet in height, surmounted by a Doric column 20 feet in diameter, with a spiral staircase in its interior; and on the summit is a statue of Washington 13 feet high. The "Battle Monument," also of white marble, was erected by public subscription in 1815, to the memory of those who had fallen in defence of the city in the previous year. It is 52 feet high; the base is of Egyptian architecture; the column in the form of a bundle of Roman fasces, upon the bands of which are inscribed the names of those whom it commemorates; and the whole is surmounted by a female figure, the emblematical genius of the city. This city is supplied with water from an elevated part of Jones's Falls, by an aqueduct half a mile in length, and distribution pipes. There are also numerous public springs and fountains throughout the town.

The manufactures and commerce of Baltimore are very extensive and flourishing. There is scarcely a branch of industry that is not prosecuted to some extent in the city or its vicinity. Among these are shipbuilding, iron and copper works, woollen and cotton manufactures, pottery, sugar refining, distilling, saddlery, agricultural implement making, cabinet-making, tanning, &c. It is the greatest flour-market in the Union, and has a large export trade in tobacco. There belonged to the port of Baltimore, on the 30th June 1852, 159,408 tons of shipping; of which 63,608 tons were engaged in the coasting trade. There are twelve banks, with a capital (in 1853) of $7,291,415; ten fire and marine and one life insurance company, besides several agencies for other companies. The aggregate value of the different descriptions of property assessed in Baltimore for the year 1846 was $86,103,673; and for the year 1853, $104,801,438, being an increase of $18,697,765.

The harbour is excellent, and consists of three parts. Its entrance, between Fort M'Henry and the lazaretto, is about 600 yards wide, with 22 feet of water. This depth is continued with an increased width for a mile and a quarter, to near Fell's Point. The entrance to the second harbour is opposite Fell's Point, where the width is contracted to one-fourth of a mile, with a depth of 12 feet. Above this entrance it widens into an ellipse of a mile long, half a mile broad, and 15 feet deep. The third or inner harbour has a depth of 10 feet, and penetrates to near the centre of the city. Vessels of 500 or 600 tons can lie at the wharfs near Fell's Point, and those of 200 tons can come into the inner harbour. The harbour is well defended by Fort M'Henry.

The railroads of Baltimore are—the Philadelphia Wilmington and Baltimore line, opened in 1837—length, 98 miles; the Baltimore and Susquehanna, to York in Pennsylvania, opened in 1846—length 85 miles; the Baltimore and Ohio, to Wheeling, a branch of which goes to Washington, opened in 1853—length, including branches, 421 miles. It is in contemplation to extend the Baltimore and Ohio railroad to Parkersbury, and the Baltimore and Susquehanna railroad to Sunbury. It is also proposed to connect a branch to the Central Ohio railway at Zanesville with the Baltimore and Ohio line. See *Gazetteer of the United States*; De Bow's *Industrial Resources, &c., of the Southern and Western States*; Hunt's *Merchants' Magazine*.

Baltinglass || Baluze.

BALTINGLASS, a town of Ireland, county of Wicklow, on the river Slaney, 37 miles S.S.W. of Dublin. It formerly carried on a manufacture of linen and woollen cloths, but its trade is now confined to bleaching. Here an action took place in 1798 between the royalists and the insurgents, in which the latter were defeated. It has the remains of an ancient Cistercian abbey and a castle. Before the Union it returned two members to the Irish parliament. Pop. in 1851, 1572.

BALUE, JEAN, a French cardinal who raised himself from a very mean station to dignity and honours. He became almoner to Louis XI., and eventually obtained the whole management of the government; but being detected in a treasonable correspondence with the Duke of Bourgogne, he was shut up by Louis in an iron cage eight feet square, a punishment he richly merited by his crimes. On his release, however, eleven years afterwards, he was loaded with honours by Sixtus IV. He died at Ancona in 1491.

BALUSTER, a small kind of pillar used for balustrades.

BALUSTRADE (Spanish, *Balustrada*), a series or row of balusters joined by a rail, and serving as a fence or inclosure to balconies, altars, staircases, &c.

BALUZE, ETIENNE, a writer eminently distinguished by his knowledge of history, ecclesiastical antiquities, and the canon law, was born at Tulle on the 24th of December 1630, of a family which had long adhered to the legal profession. He received his elementary education at the place of his nativity, and afterwards prosecuted his studies in the university of Toulouse, where he obtained an exhibition in the College of St Martial. Having finished his course of philosophy, he commenced his attendance in the schools of law; but although he attained to great proficiency in certain departments of jurisprudence, he felt no inclination for the ordinary occupations of a lawyer, and never followed the profession of an advocate. His earliest inquiries related to different subjects of ecclesiastical antiquities; and the reputation which he thus acquired recommended him to the notice of M. de Montchal, archbishop of Toulouse, who granted him access to his library. This prelate was succeeded by M. de Marca, soon afterwards archbishop of Paris, a man who was profoundly skilled in those branches of knowledge which Baluze so long continued to cultivate. In 1656 Baluze was invited by the archbishop to the metropolis; but before his hopes of preferment were realized, his patron died.

He speedily found another favourer of his studies in M. le Tellier, afterwards chancellor of France, who conferred upon him many benefits. He was next connected with the establishment of M. de Lamothe-Houdancourt, archbishop of Auch. In 1667 M. Colbert offered him the situation of keeper of his library, one of the most magnificent private collections in Europe; and its value, both in manuscripts and in printed books, was greatly augmented by the judgment and zeal of the learned librarian. Having retained his office for some time after the death of Colbert, he resigned it in the year 1700, and retired to a house belonging to the Scottish College.

In 1670 he was appointed professor of the canon law in the Royal College, a new chair which the king was pleased to erect in his favour; and of his high qualifications for such a professorship he has left the most unequivocal proofs. He was also appointed a canon of the cathedral of Rheims; and in the privilege appended to his edition of Marius Mercator, printed in the year 1684, he is designated "Estienne Baluze, prieur de Beauvais." It may therefore be inferred that he enjoyed a considerable pension from that abbey; nor were such arrangements uncommon at that period of the history of France. He is described as "simple tonsuré;" an expression which denotes that he was not a priest or a deacon, but had only been initiated into one of the lowest of the seven holy orders. In 1683 he published a

Balzac.

volume of Councils, and it was his original intention to extend the collection; but as some of the materials which he had prepared could not be much relished at Rome, he thought it expedient to abandon his design. Of the acts of the council of Basle he had proposed to print a very ample collection; and this was indeed the part of his plan for which the whole had chiefly been undertaken. After an interval of ten years, he published his Lives of the Popes of Avignon; a work of curious research, which procured him a pension from the crown, and afterwards the office of director of the Royal College, where he succeeded the Abbé Gallois in the year 1700. But the favour of a court is at all times and in all places held by a very precarious tenure. Baluze, who had attached himself to Cardinal de Bouillon, was involved in the disgrace which attended that prelate. A *lettre de cachet* removed him from Paris: his place of exile was repeatedly changed, and his residence successively restricted to Rouen, Blois, Tours, and Orleans; nor could he obtain his recal till 1713, after the peace of Utrecht. Though at length permitted to revisit Paris, he never recovered his two offices of director and professor of the Royal College. This persecution did not however quench his literary ardour; for, during his exile, he employed himself in preparing an edition of the works of St Cyprian, which was published after his death. His constitution had never been vigorous, but the sobriety and regularity of his habits enabled him to reach a mature and healthy old age. He died on the 28th of July 1718, in his eighty-eighth year; and was buried in the church of St Sulpice. A person who had lived so long in the midst of learned dust, without either wife or children to blow it aside, could not well be without his share of peculiarities. He was not entirely exempted from caprice, and his testament exhibited this caprice in no very amiable light; his relations and domestics were almost totally forgotten, and the bulk of his property was bequeathed to a woman who appears to have had no claim upon him. Some scholars, who have collected libraries with much labour and at great expense, are inclined to cherish an anxious wish that they should be preserved entire; but, on the contrary, he was desirous that his library should be sold in detail, lest any one individual should be put in possession of those literary treasures which he himself had gradually amassed. This collection consisted of 10,799 articles, including more than 1500 manuscripts, together with 115 printed books which he had interspersed with annotations. The manuscripts were added to the Royal Library.

The merits of Baluze are perhaps more conspicuous in his capacity of editor than in that of author. If his labours had not extended beyond the *Capitularia Regum Francorum*, his name would always have been mentioned with respect by lawyers and historians; but some of his other publications greatly illustrate the history of the middle ages; nor must we forget the light which they reflect upon the history of the canon law, and upon the writings of the Latin fathers. His published works formed fifteen volumes in folio, three in 4to, sixteen in 8vo, and two in 12mo. (D. I.)

BALZAC, Honoré, one of the most distinguished and most prolific of the modern French novelists, was born at Tours on the 20th May 1799. After completing his studies at Vendôme, he entered the office of a notary at Paris, and commenced his literary career by contributions to periodical works; which attempts, however, gave little indication of his genius. Between the years 1821 and 1829 he published, under various pseudonymes, no fewer than thirteen romances; and in the last-mentioned year appeared the first work to which he affixed his name. His writings display a profound knowledge of the human heart, and several of them bear the stamp of unquestionable genius; such, for example, as *La Peau de Chagrin, Le Dernier Chouan, La Physiologie de Mariage, Le Pere Goriot, La Femme de Trente Ans;* and his later works, *Medecin de Campagne,* and *Parens Pauvres.* The most remarkable feature in his private history was his deep attachment to the Countess Eveline Hanska, a Russian princess, who rewarded his long and untiring devotion with the gift of her hand in 1848. Balzac did not long enjoy his felicity. He died at Paris, of hypertrophy of the heart, on the 30th of August 1850. His remains, attended by a vast concourse of people, were deposited in the cemetery of Père-Lachaise.

Balzac || Bamboo.

Balzac, *Jean-Louis-Guez de*, was born at Angoulême in 1594. He was one of the most popular writers of his day, but his works have long since sunk into comparative obscurity. Voltaire allows him the merit of having been the first who gave numbers and harmony to French prose, but censures his style as bombastic. His writings extend to two folio volumes, which were published in that form in 1665, with a preface by the Abbé Cassaigne; but his reputation rests chiefly on his *Letters.* He died in 1655, and was buried in the hospital of Nôtre Dame des Anges, to which he bequeathed 12,000 livres. He also left an estate of 100 francs per annum for a gold medal to be bestowed every two years for the best discourse on some moral subject. This prize is still continued.

BAMBA, a province of Congo, on the western coast of Africa, lying to the S. of the river Ambriz. This district is said to be very fertile, and to abound in gold, silver, copper, salt, &c. Its chief town bears the same name.

BAMBARRA, an extensive and important country of interior Africa, with which the journeys of Park, who was perhaps the first European that reached it, have made us tolerably acquainted. It is situated between the 5th and 9th degrees of W. Long., and the 12th and 15th of N. Lat. See Africa.

BAMBERG, a town of Bavaria, in the circle of Upper Franconia, on the river Regnitz, 3 miles above its junction with the Maine, and 33 miles N. of Nuremberg, with which it is connected by railway. It is partially surrounded by walls and ditches, and is divided by the river into three districts, which are connected by two handsome bridges. The town is well built, and the streets are well paved and lighted. The cathedral, a noble structure in the Byzantine style of architecture, is surpassed by few of the kind in Germany. It was founded in 1004 by the Emperor Henry II., and finished in 1012, but was afterwards partially burnt, and rebuilt in 1110. It contains the tombs of the founder and his empress Kunigunde, Konrad III., Pope Clement II., &c.; and numerous monuments and paintings by the most eminent masters. Among the other public buildings are St Martin's church, the church and convent of St Michael, the palace formerly the residence of the prince-bishops, town-house, and theatre. It has numerous literary and charitable institutions, as the lyceum, gymnasium, polytechnic, normal, and medical schools; library, museum, picture-gallery, hospital, and workhouse. There is a very considerable trade here, and manufactures of cloths, sealing-wax, leather, tobacco, musical instruments, carriages, &c., besides numerous breweries. The Bamberg beer is in much repute. Bamberg was formerly the capital of an independent bishopric, which was secularized in 1801, and assigned to Bavaria in 1803. Pop. (1849) 18,531.

BAMBOCCIO, a celebrated painter, born at Laeren, near Naarden, in Holland, in 1613. His name was Peeter van Laer; but in Italy he was called Bamboccio, on account of the strange proportions of his person. Nature, however, made him amends in the superior beauties of his mind. His style of painting was sweet and true, and his touch delicate, with great transparency of colouring. His subjects were taken from scenes in humble life, such as plunderings, playing at bowls, inns, cattle, conversations, &c.; yet his designs were so correct, and so highly finished, that his manner was adopted by many Italian painters of his time.

BAMBOO. This plant was ranked by the older botanists

Bamboo. in the number of reeds; but some, less sensible of its analogies with them, instituted for it a separate genus. In the *Systema Naturæ*, Linnæus describes two species, under the genus Arundo-Bambos, now termed *Bambusa*, which is characterized thus: "scales three, covering the spikelets, which are about five flowered; calyx none; corolla, a two-valved glume; style bifid; seed one." Roxburgh describes about thirty kinds of Bambusæ: but the species of Roxburgh have been by later botanists subdivided into several other genera; and we now find but a few species considered as true Bambusæ. Thus, in Willdenow's *Species Plantarum* there are but two recognised, *B. arundinacea* and *B. verticillata*. In the *Systema Vegetabilium* of Sprengel, there are three species, *B. arundinacea*, *B. spinosa*, *B. stricta*.

Loureiro, who had an opportunity of studying the nature of the bamboo in its own climate, characterizes it as having "flowers with six stamina; panicle diffused, with imbricate spikelets; branches of the culm spiny; calyx one flowered." The *Bambusa arundinacea* is a native of the warmer climates only, though growing luxuriantly without the limits of the torrid zone. It rises to the height of forty, sixty, or even eighty feet, with a hollow stem, shining as if varnished. The stem is extremely slender, not exceeding the thickness of five inches in some which are fifty feet high, and in others reaching fifteen or eighteen inches in diameter. The whole is divided into joints or articulations, separated by a short interval, called a knot or internode; and in some there is the distance of several feet between each. These joints or divisions are formed by the crossing of the vascular bundles of fibres. They produce alternate lateral buds which form small alternate branchlets springing from the base to the top, and together with the narrow-pointed leaves issuing from them, give the tree an elegant feathered appearance as it waves in the wind.

The rapidity of its growth is surprising. It sometimes grows three or four inches in a single day. Accurate observers have seen it rise twenty feet, and expand as thick as a man's wrist, in five or six weeks; and it has been known to reach thirty feet in six months. This enables us to credit the assertion, that its full dimensions are attained in a year; and that the only subsequent change is greater thickness and induration of the wood. In Malabar it is said to bear fruit when fifteen years old, and then to die.

The bamboo grows wild in most places of the East, and the warmer parts of the West. Where the country is principally dependent on its use, it is cultivated in regular plantations. It apparently succeeds best in low sheltered grounds, with rich, soft, spongy earth; but humidity is especially prejudicial to it. This plant is propagated by shoots deposited in pits at the close of autumn or commencement of winter, eighteen inches or two feet deep; and in order to obtain bamboos of considerable size, the scions are cut over as they spring up. Their subsequent treatment depends entirely on the uses to which they are to be converted; much care being bestowed on those designed for beauty or ornament only. They are propped up with rods; and, if complete plants, are cut over in order to obtain suitable shoots. It is necessary to surround the plantation with a ditch, in order to drain off superabundant humidity, which would otherwise be prejudicial. Various expedients are followed to obtain good bamboos; one of the most usual being to take a vigorous root and transplant it, leaving only four or five inches above the joint next the ground. The cavity is then filled with a mixture of horse-litter and sulphur. According to the vigour of the root, the shoots will be more numerous; but they are destroyed at an early stage during three successive years; and those springing in the fourth resemble the parent tree. It is affirmed that no culture can obtain any thing of larger size.

The utility of this plant soon becomes conspicuous. The Bamboo. soft and succulent shoots, when just beginning to spring, are cut over and served up at table, like asparagus. Like this vegetable, also, they are earthed over to keep them longer fit for consumption; and they afford a supply in succession during the whole year, though more abundantly in autumn. They are also salted and eaten with rice, or prepared after different other fashions. As the plant grows older, a kind of fluid of grateful taste and odour is secreted in the hollow joints, affording a considerable quantity of an agreeable beverage. If allowed to remain in the tree, a concrete substance, highly valued for its medicinal properties, called *tabaxir* or *tabascheer*, is produced from it. The presence of the fluid is ascertained by agitating the bamboo; after some time its quantity gradually diminishes, and then the stem is opened to reach the tabascheer. This substance, participating in nothing of a vegetable nature, has been found to be siliceous earth; it resists the impression of all acids, is indestructible by fire, and with alkalies forms a transparent glass. Notwithstanding its repute in the East, it has never been received into the European materia medica. Besides the tabascheer, many parts of the bamboo are said to be endowed with medicinal properties; a decoction of the leaves is recommended for coughs and sore throat; the bark for fever and vomiting; the buds as a diuretic; and a compound of the root with tobacco-leaves, betel nut, and oil, is believed to form an efficacious unguent. But setting aside its medicinal properties, it is highly valuable as an article of food; for many of the poorer classes in the most populous countries subsist on it in times of scarcity. Its seed is recorded in Chinese history to have preserved the lives of thousands. The Hindus eat it mixed with honey as a delicacy, equal quantities of each being put into a hollow joint, coated externally with clay, and thus roasted over a fire.

From the copious draught which a joint of the bamboo naturally yields, mankind are taught its use as a vessel for carrying water, and in some places no other bucket is employed. The Eastern nations build their houses solely of the wood, without any auxiliary substance: if entire, it forms posts or columns; split up, it serves for floors or rafters; or interwoven in lattice-work, it is employed for the sides of rooms, admitting light and air. The roof is sometimes of bamboo solely, for which two species growing in Laos, an Asiatic country, are described as specially adapted; and when split, which is accomplished with the greatest ease, it can be formed into laths or planks. It is employed in shipping of all kinds; and as houses are constructed entirely of it, so are complete vessels framed out of it, and fitted for sea. The hull is obtained from the stem; and some of the strongest plants are selected for masts of boats of moderate size. In Bengal a boat of four or five tons may be furnished with both mast and yard from the same bamboo, at the cost of threepence; and the masts of larger vessels are sometimes formed by the union of several bamboos built up and joined together. Those of considerable dimensions are used in the higher yards of ships of four or five hundred tons, for which service they are well adapted by their great strength and lightness.

The bamboo is employed in the construction of all agricultural and domestic implements; and in all materials and implements required in fishery, hooks and nets excepted. In Tibet the strongest bows are made of it, by the union of two pieces with many bands; and, in the same country also, it is employed, as we use leaden pipes, in transmitting water a distance of several miles to reservoirs or gardens. The species from which these pipes are constructed is said to grow in the mountains; and from other light and slender stalks the inhabitants obtain shafts for their arrows. In the south-west of Asia there is a certain species of equally slender growth, from which writing pens or reeds are made.

From the extreme flexibility of this substance, and also

Bamborough || Bambouk.

its divisibility, for it splits like whalebone from top to bottom, it can be reduced to the smallest dimensions, and bent into every shape. It is woven into baskets, cages, hats, or various ornamental articles. By a particular process in bruising and steeping the wood or bark, a paste is procured that is made into paper. In short, from its very origin until its decay, it never ceases to produce something beneficial. It has justly been observed: "All that composes a bamboo is profitable, of whatever species it may be. The artists of China have each made their choice, and, in the works they produce, show the advantages they have derived from it. Its uses are so numerous, so various, and so beneficial, that it is impossible to conceive how China could now dispense with this precious reed. It is no exaggeration to affirm, that the mines of this vast empire are of less importance to it than the possession of the bamboo; which, we may add, is also the chief instrument of government."

Some European climates might not prove noxious to the bamboo; but the same rapidity of vegetation, the same natural qualities, could not be expected, or only in an inferior degree, even in the most favourable situation, and consequently its utility would be greatly diminished. (J. G. D.)

BAMBOROUGH, a village in Northumberland, on the sea-coast, fourteen miles north of Alnwick, and once a royal borough. Its very ancient castle stands on an almost perpendicular rock close to the sea, and is accessible only on the south-east side, on a spot where the castle or palace of the kings of Northumberland, supposed to have been built by King Ida, who began his reign about the year 547, is said to have stood. The castle and property connected with it were vested by Lord Crewe, bishop of Durham, in trustees, for charitable purposes, in virtue of which a patrol is kept on the coast, apartments are provided for shipwrecked seamen, together with a storehouse for goods, &c. saved from wrecks; and other apartments are used as granaries for corn, to be sold cheap to the poor in times of scarcity. Bamborough has an infirmary and dispensary, with a resident surgeon, and also a large library. Pop. in 1851, 466.

BAMBOUK, a country in the interior of Western Africa, situated between the Ba-Fing and the Faleme, the two great upper tributaries of the Senegal. The chief characteristic of this country is the quantity of gold with which its soil is almost universally impregnated.

The Portuguese, it appears, penetrated early into Bambouk, and were even for some time masters of the country; but the inhabitants, inflamed by their oppressions, made a general rising, and completely drove them out. The French, when they formed their settlement on the Senegal, soon directed their eager search towards a country abounding in so valuable a commodity; but their efforts to penetrate into it proved for a long time abortive. At length, in 1716, one Compagnon succeeded, by great address, and not without risk, in gaining the favour of some leading persons, and obtaining a view of the mineral treasures of this country. David and Levens, two successive French governors, afterwards contrived to effect an entrance. Sieur Brue, the most enterprising of the governors of Senegal, laid before the French administration a plan by which, with 1200 men, he undertook to conquer and maintain Bambouk. Such an expedition might very probably have been in the first instance successful, and the French might probably, by skilful working, have greatly increased the produce of the mines; but when we consider the various casualties and difficulties attendant on the occupation of this interior region, it must appear very doubtful if this would have been in the end a profitable possession.

Bambouk is fertile and populous along the banks of the rivers, but many of the interior districts are arid and barren. There is a king, but the farims or chiefs compose nearly an independent feudal body. The population is Mandingo, yet the Mahometan religion is professed; but the observance consists chiefly in some outward ceremonies, and the marabouts or priests of that faith are carefully excluded from the kingdom. (H. M.)

Bamiyán || Banat.

BAMIYAN, a fertile valley of Afghanistan, traversed by the route from Kabul to Turkistan, and bounded on each side by lofty and almost perpendicular steeps. The pass is of importance both in a military and commercial point of view, having less elevation and fewer difficulties than other passes in its vicinity, and being the only one across the Hindu Koh practicable for artillery or heavy carriages. Bamiyan and its vicinity are celebrated for some of the most remarkable relics of antiquity; its colossal idols, the castle of Zohak, and the ruins of Ghulghalch, which are scattered over the valley. The town of Bamiyan is in Lat. 67. 50. Long. 34. 50. (E. T.)

BAMPTON, or Bampton-in-the-Bush, a market-town of Oxford, hundred of Bampton. It stands in a flat situation near the banks of the Isis, 70 miles from London, and 14 from Oxford. The church is a magnificent ancient edifice. Pop. of town and parish in 1851, 2780. Market-day Wednesday.

Bampton, a market-town in Devonshire, hundred of Bampton, 164 miles from London, and 21 from Exeter. It formerly returned two members to parliament. Pop. of town and parish in 1851, 2102. Market-day Saturday. A great battle was fought here A.D. 614, between the West Saxons and Britons, in which the former were defeated.

BAN, Banus, a Slavonian word signifying *lord*, an ancient title belonging to the wardens of the eastern marches of Hungary, and corresponding somewhat in dignity to that of the ancient margraves of the empire. The ban was equal in dignity to the palatine of Hungary, and took rank next to the king, with whom he had in his own province equal powers. The country under his jurisdiction was called a banat. This dignity is confined in modern times to the viceroy of Temesvar, who is called the ban of Croatia, and holds the third rank among the secular nobles of Hungary.

Ban or Bann (from the Saxon *bannan*, to proclaim, to send forth) is a public notice or edict, whereby a thing is commanded or forbidden. In France the word *ban* has generally been confined to the simple sense of a public proclamation. The word *banns* is used in England and in Scotland in publishing matrimonial contracts; which is done in church before marriage, to the end that if any persons can speak against the intention of the parties, either in respect of kindred, precontract, or other just cause, they may take their exception before the marriage be consummated. The use of matrimonial banns is said to have been first introduced into the Gallican church, though something like it obtained even in the primitive times; and it is this that Tertullian is supposed to mean by *trinundina promulgatio*.

The word is also used to denote proscription or banishment for a crime proved, because anciently published by sound of trumpet; or, as Vossius thinks, because those who did not appear at the above-mentioned summons were punished by proscription. Hence, "to put a prince under the ban of the empire," was to declare him divested of all his dignities. In an ecclesiastical sense, in like manner, it signifies a solemn anathema, or excommunication attended with curses. Such was the ban of the pope.

BANAGHER, a market-town of Ireland, King's County, on the river Shannon. Pop. in 1851, 1846. It is 81 miles W.S.W. of Dublin.

BANALBUFAR, a town on the western coast of the island of Majorca. It produces good wine. Pop. 5000.

BANANA, *Musa sapientum*, an herbaceous plant, a native of the West Indies. Its fruit is produced in large clusters weighing many pounds, and forms a considerable article of food among the better classes.

BANAT, an old province of Hungary, of which the capital was Temesvar. It extended from the Maros on the N. to the Danube on the S., and from Transylvania and

Banbridge || Banda Islands.

Wallachia on the E. to the Theiss on the W., comprehending the present counties of Torontal, Temesh, and Krassova. See HUNGARY.

BANBRIDGE, a town of Ireland, county of Down, on the Bann, 23 miles S.W. of Belfast. It occupies the summit of an eminence. To facilitate the access, a central carriage-way 200 yards long has been cut through the main street to a depth of 15 feet, the opposite terraces being connected by a bridge. It is a neat town, with a handsome church, several chapels, and a new market-house; and it has extensive cloth and thread factories, bleachfields, and chemical works. It is the principal seat of the linen trade in the county. Pop. in 1851, including the workhouse, 3779.

BANBURY, a market and borough town in the county of Oxford, 71 miles from London. It is well built, containing many respectable houses; and is watered by the River Cherwell. The corporation consists of a mayor, four aldermen, and twelve councillors. Banbury returns a member to parliament. It has some manufactures, but depends chiefly on the villages around it, which send their agricultural produce to the market, which is held on Thursday. The Oxford and Birmingham canal passes here. Pop. of borough in 1851, 8715.

BANCA, BANKA, or BANGKA, an island off the east coast of Sumatra, and separated from it by the Strait of Banca. It lies between Lat. 1. 30. and 3. 7. S. and Long. 105. 9. and 106. 54. E. It varies from 8 to 20 miles in breadth, and has an area of 3560 geographical square miles. Its mines of tin, which were discovered in 1710, are remarkably productive, and in 1844 yielded no less than 70,289 peculs, or 4183 tons 18 cwt. of that metal. Iron, copper, lead, silver, and arsenic, are also found there. The soil is generally dry and stony, and the greater part of the island is covered with forests, in which the logwood tree especially abounds. Its mountains, which scarcely exceed 2000 feet in height, are covered with vegetation to their summits. They are of granitic formation, containing felspar, quartz, mica, and tourmaline. Pop. in 1840, 35,000, including 18,000 Chinese. Muntak, the capital, has 3000 inhabitants, and a fort garrisoned by 200 men. There are several other forts on the island. It belongs to the Dutch.

BANCOORA, a town of Hindustan, in the presidency of Bengal, and the chief place of the district of the same name, is situate on the route from Calcutta to Benares, 100 miles north-west of the former. The district of which it forms the capital has an area of 1476 square miles, and contains a population of 480,000. It occupies a portion of the valley of the River Damooda, in which is situate the great carboniferous and iron-ore tract of Bengal. A branch from the East Indian railway, diverging near the city of Burdwan, and proceeding to Raneegunge, in the north-west angle of the district, where the most valuable collieries are situate, is now under construction. The town of Bancoora is distant from Burdwan W. 60 miles. Lat. 23. 14. Long. 87. 6. (E. T.)

BANDA, a town in Hindustan, the principal place of a district of the same name, situate in the territory constituting the lieutenant-governorship of Agra. The town is built at the base of a hill rising 300 or 400 feet above the surrounding plain, but though of considerable size and a thriving place, being the great mart for cotton, the houses, with the exception of the palace of the Nawaub of Banda, are of inferior construction. This prince is a descendant of the former native governors of Bundlecund. He has no hereditary dominions; but enjoys an allowance of L.40,000 per annum, guaranteed to him and his heirs in perpetuity by the British government. The district of Banda has an area of 2878 square miles, and a population of 552,556. The town is distant from Calcutta 560 miles. Lat. 25. 28. Long. 80. 23. (E. T.)

BANDA ISLANDS. These islands, belonging to Holland, are 130 miles to the S.E. of Amboyna, between Lat. 3. 50. and 4. 40. S. They are ten in number, viz. Banda Neira, Gonong Apee, Banda Lantoir, Pulo Ay or Way, Pulo Rondo or Pulo Roon, Rosyngen, Pulo Pisang, Craka, Capella, and Sonangy. Banda Islands.

Of these, Banda Neira is the seat of the supreme government. It is protected by one principal fortification, situate on the south side of the island, and consisting of a small square fort, with a wet ditch, and a horn-work towards the sea. This fortification, which is called Fort Napau, forms the chief defence of the Banda Islands. The troops are quartered, and the public granaries are kept in this fort; but the storehouses for the nutmegs and mace are on the outside, as well as the government-house. Above Fort Napau, on a neighbouring eminence, stands the castle of Belgica, an old pentagon, with round towers at the angles. It is surrounded with a wall, secured by small bastions, but has no ditch. It is said to have been built by the Portuguese.

Banda Lantoir or Great Banda is to the northward of Banda Neira. It is protected by a considerable fort, called Fort Hollandia, which also commands the harbour. At first view the situation of this fort appears preferable to Banda Neira for the residence of government, not only on account of its strong and commanding situation, but because the island is the largest as well as the richest in the produce of spices. Its unhealthiness has been found, however, to be a sufficient objection. The water is said to be bad, and the vapour which sometimes descends from the volcanic mountain of the neighbouring island, Gonong Apee, is represented as particularly noxious. Such fatal effects were produced by these causes, that when the Wirtemberg Company formerly garrisoned the island, out of a hundred men eight died and forty fell sick in the course of two months. The numbers of decayed houses, also, which are seen in different parts of the island, show that the experiment of a settlement has already been tried, and has not been found successful. From the sea this island appears very high; its sides are steep, and from the top of them there is a sort of table-land, which extends nearly from one end of the island to the other.

Gonong Apee is to the northward of Banda Neira, and derives its name from a large volcano about 2000 feet above the level of the sea, which constantly emits smoke, and sometimes cinders and ashes, accompanied with a crackling noise. On the south side of this island are two forts, originally intended to defend the west channel of Lantoir harbour; but, owing to an eruption of the volcano in 1778, at the same time that a dreadful hurricane laid waste the island, the lava flowed down in such quantities as to form a considerable promontory between these batteries and the channel they were intended to defend, so that they are now in a great measure useless. This island is generally unproductive, its surface being covered with a quantity of sulphur and chalk. There is no vegetation whatever on upwards of one third of the eminence on which the volcano is situated.

Pulo Way is about nine miles to the westward of Gonong Apee, and is defended by a strong fort. It is esteemed the most healthy of the whole group, and produces abundance of nutmegs, of a kind superior in quality to those of the other islands. Pulo Rondo, or Pulo Roon, is about four miles farther, in a somewhat more northerly direction. On this island the English had a factory, from which they were expelled by the Dutch about the period of the massacre of Amboyna; and the island having been since abandoned, has become a wilderness. Rosyngen is about seven miles to the S.E. of Lantoir. It produces nutmegs, mace, yams, and subsistence for a few cattle. The convicts of Amboyna were formerly kept on this island, and were compelled to cultivate the land for the use of the supreme government. Pulo Pisang is about two miles N.E. from Banda Neira, and yields some fine fruits, as well as nutmegs and mace. The other three islands are uninhabited, being little more than barren rocks.

Banda Oriental. || Bandaleer.

The Banda Islands were discovered in the year 1511 by the Portuguese, who immediately took possession of them in the name of their sovereign. About the year 1603 they were expelled by the Dutch. In 1608 the English, with the permission of the king, built a factory-house on Pulo Way, which the Dutch demolished as soon as the ship which brought out the factors returned to England. The natives of Banda, notwithstanding the opposition of the Dutch, assisted the English in forming a new colony; and shortly afterwards they, along with the natives of Lantoir, made a formal resignation of their respective islands to the new settlers. In 1620 Pulo Roon and Pulo Way were added to the English dominions, and these cessions were confirmed by a treaty concluded between the English and the Dutch. But, in defiance of this treaty, the latter determined on the expulsion of their rivals from those islands, in the possession of which they appeared to be gradually establishing themselves. They accordingly attacked them with a strong force, seized their factories, magazines, and shipping, and, after stripping the factors naked, first whipped and then loaded them with irons. Some notion may be formed of the trade, then in its infancy, by the quantity of spices seized here, which amounted to 23,000 lb. of mace and 150,000 lb. of nutmegs. In 1654 the Dutch were compelled, by the firmness of Cromwell, to restore the island of Pulo Roon, and to make satisfaction for the massacre af Amboyna. But the English settlers not being adequately supported from home, were unable to resist the power of their rivals, and the island was retaken by the Dutch in 1664. They retained undisturbed possession of their conquests in this quarter of the globe until the year 1796, when the Banda Islands, along with all the other Dutch colonies, were conquered by the British. They were restored by the treaty of Amiens in the year 1800, again captured, and finally restored by the treaty of Paris concluded in 1814.

In the space between Banda Lantoir and the islands of Banda Neira and Gonong Apee there is a very good harbour formed with entrances both from the E. and W., which enable vessels to enter it from either of the monsoons. These channels are well defended with several batteries, particularly the western one, which is very narrow. Between Gonong Apee and Banda Neira there is a third channel into this harbour from the N., but it is navigable only for small vessels.

The great articles of commerce in these islands are nutmegs and mace. The islands of Banda Neira, Banda Lantoir, and Pulo Ay, are exclusively devoted to the cultivation of the nutmeg; and the restrictions imposed by the government constitute a monopoly of this produce in the hands of the Dutch East Company. The laws and regulations generally established are calculated to support and promote the monopoly of these products rather than the happiness of the people or the improvement of the country. The annual produce amounts to about 420,000 lb. of nutmegs and 140,000 lb. of mace. They are divided into large plantations, to each of which a certain number of slaves or convicts is attached. In 1840 the population was 5081, distributed as follows:—In Banda Neira and Gonong Apee, 1223; Lantoir, 372; Pulo Ay, 148; Pulo Roon, 42; Rosyngen, 84; slaves, 2183; and convicts, 1029. See Temminck, *L'Inde Archipelagique.*

An account of the nutmeg tree and its cultivation is given under Myristica.

BANDA ORIENTAL. See Uruguay.

BANDALEER, or Bandoleer (from the Dutch *band*, and *leer, leather*), a large leathern belt thrown over the right shoulder, and hanging under the left arm. It was worn by the ancient musketeers for sustaining their fire-arms, and for holding their musket charges, which, being put up in little wooden cases coated with leather, were hung, to the number of twelve, to each bandaleer.

Bandanna || Bandello.

BANDANNA, a term of Indian origin for a kind of calico-printing, in which white or bright-coloured spots appear on a Turkey-red or dark ground.

BANDELLO, Matteo, a celebrated Italian novelist, born at Castelnuovo, near Tortona, about the year 1480. In his youth he studied both at Rome and at Paris; and his education being completed, he went to reside at Mantua. There he remained for several years, much esteemed by Pirro Gonzaga, who intrusted him with the education of his daughter, the celebrated Lucrezia Gonzaga. The incidents in the lives of the literary men who flourished in Italy during the sixteenth and seventeenth centuries have in many respects a strong similarity. Like most of his literary contemporaries, Bandello passed from one petty court to another, and was frequently employed in political missions by the patron whom he served at the time. At this period the small states of Italy were divided between the French and Spanish interests. Bandello had chiefly attached himself to those princes of Lombardy who favoured the French party; and, in consequence, when the decisive battle of Pavia put the Spaniards in possession of Milan, where Bandello at that time resided, his paternal mansion was burned, and the property of his family confiscated. He fled in disguise from Milan, and after wandering from town to town, he placed himself under the protection of Cesar Fregoso, a celebrated captain of that age, who had recently quitted the Venetian for the French service. With this general Bandello resided in Piedmont, till a truce was concluded, when he accompanied his patron to France. After the death of Cesar he continued to live with his widow and family at Agen, to the bishopric of which he was raised by Francis I. in 1550, and continued to reside in the vicinity of that town till his death, which happened about 1562.

During his residence at Agen, Bandello revised and added to the novels which he had written in Italy during his youth, and which some of his friends had recovered from the hands of the Spanish soldiers who burned his house at Milan. His *Tales* were first published at Lucca in 1554, 4to. In the complete editions of Bandello, the work is divided into four parts; the first, second, and third parts containing fifty-nine stories, and the fourth comprehending twenty-eight. The whole are dedicated to Ippolita Sforza, though she died before their publication, because it was at her desire that the work was originally undertaken. Besides this general dedication, each novel is addressed to some *Valoroso Signore*, or *Chiarissima Signora;* and in these introductions the novelist generally explains how he came to a knowledge of the event he is about to relate. He usually declares that he heard it told in company, details the conversation by which it was introduced, and pretends to report it, as far as his memory serves, in the exact words of his authority.

Bandello is chiefly indebted for his celebrity to these novels, which belong to a class of composition that enjoyed for many centuries the utmost popularity in Italy. The tales of the French Trouveurs, having passed into Italy towards the close of the thirteenth century, were first imitated in the *Cento Novelle Antiche;* which also contains stories formed from episodes in the romances of chivalry, the ancient chronicles of Italy, and jests or repartees preserved by oral tradition. Boccaccio, whose *Decameron* appeared shortly after, identified this species of composition with the history of Italian literature and the progress of the Italian language. That celebrated writer was followed by Sacchetti, Ser Giovanni, Centhio, and a numerous tribe of imitators, of whom Bandello is by much the best known and most celebrated, at least in this country. His popularity, however, has not been so great in Italy, which may probably be attributed to the negligence and impurity of his style; a fault of which the author himself appears to have been conscious, as he repeatedly apologizes for his defects in elegance of diction. *Io non sono Toscano, nè bene intendo la proprietà di quella*

Bandinelli. *lingua ; anzi mi confesso Lombardo.* Napioni, in his eulogy of Bandello, confesses that he is not remarkable for that harmony of periods, and delightful *naiveté* of expression, for which Boccaccio and others of his predecessors were so distinguished; but he adds, that none of the Italian novelists is so interesting for the development and illustration of minute historical facts, which would in vain be sought for in the histories of the revolutions of the Italian states. Some of the novels of Bandello, however, it must be admitted, are little edifying; and it is curious that one of his stories, which is perhaps the most obscene in the whole series of Italian novels, should be declared, in the introduction, to have been related by the celebrated Navagero to the Princess of Mantua and Duchess of Urbino. Besides, notwithstanding the repeated assertions of Bandello, that all his stories have some foundation in fact, and the light which his eulogists suppose that they throw on the history of the Italian republics, it cannot be denied that the greater proportion of them are derived from the Fabliaux of the French Trouveurs, and the works of preceding Italian novelists, with an alteration of the names, and some slight variations in the incidents. But while Bandello has thus copied largely from preceding fablers, none of their works has suggested more to others, or is more curious for illustrating the genealogy of fiction, and the transmission of fabulous incident from the novelist to the dramatic poet. Many of the tales of Bandello were translated by Belleforest in his *Histoires Tragiques*, whence they found their way into Paynter's *Palace of Pleasure*, and other works of a similar description which appeared in England during the reign of Queen Elizabeth. In this manner they furnished the plots of many tragedies and comedies to the most numerous and noble race of the English dramatic poets. That part of Shakspeare's *Much Ado about Nothing* which relates to Don John, Claudio, and Hero, is taken, with little variation in the incidents, from the twenty-second tale of the first part of Bandello; *The Twelfth Night* is borrowed from the thirty-sixth of the second part; and his *Romeo and Juliet* is derived from the same source (vol. ii. novel ix.). Massinger has been indebted for his *Picture*, which is, perhaps, the most agreeable and fanciful of his dramas, to the twenty-first of the first part; while Beaumont and Fletcher have derived from the same source their comedy of the *Maid in the Mill*, and the *Triumph of Death*, which is the third of their "Four Plays in One." The thirty-fifth of the second part of Bandello is the same story as the plot of Horace Walpole's *Mysterious Mother*, and the thirtieth tale of the Queen of Navarre. As the works of Bandello and the Queen of Navarre were printed nearly at the same period, it is not probable that they copied from each other; and it may be presumed, that some current tradition furnished both with the horrible incident they relate. Mr Walpole, however, disclaims having had any knowledge of the tale of the Queen of Navarre or Bandello at the time he wrote this drama. Its plot, he says, was suggested by a story he heard when very young, of a lady, who, under uncommon agonies of mind, had waited on Archbishop Tillotson, and besought his counsel in what manner she should act under the fatal circumstances that had occurred.

Besides his *Tales*, Bandello is author of a poem in eleven cantos, which was his first work, and is now very scarce, entitled *Delle Lodi della Signora Lucrezia Gonzaga*, printed at Agen, 1545, in 8vo. He also wrote a complimentary poem, in three cantos, on the birth of a son of his patron, Cesar Fregoso. Both these productions are written without taste or spirit; but it is said that some good verses, composed by Bandello, on different subjects, are still preserved in manuscript in the library of the Academy of Turin. (J. C. D.)

BANDINELLI, Baccio, a celebrated Florentine sculptor, born in 1487. His father was an eminent goldsmith, distinguished by his exquisite designs in chasing of gold and silver ornaments; and in this domestic school, Baccio, or Bartolommeo, obtained the first elements of drawing. Showing a strong inclination for the fine arts, he was early placed under Francesco Rastui, a sculptor, and he made rapid progress. He was the fellow student of Buonarotti in the garden of the Medici at Florence. As an artist, Bandinelli was very eminent; but his bad temper and arrogance made him hateful to his contemporaries, who have not in general done justice to his merit. He executed many works in marble and in bronze, of much grandeur. His best works are the marble colossal group of Hercules and Cacus in the Piazza del Gran Duco; his group of Adam and Eve; his exquisite bassi-rilievi in the choir of the cathedral of Florence; and the figures of Christ and Nicodemus on his own tomb. Bandinelli shows himself in these works an admirable master of design, and exhibits great skill in human anatomy, and in the cast of his draperies. He died at Florence in 1559. (T. S. T.)

Bandini ‖ Bandon.

BANDINI, Angelo Maria, a learned Italian, was born at Florence on the 25th of September 1726. Having been left an orphan in his infancy, he was supported by his uncle, Joseph Bandini, a lawyer of some note. He received his education among the Jesuits, and discovered an early passion for the study of antiquities. A desire which he also manifested to distinguish himself as a poet was fortunately checked by the ill success of his first attempt; and, from that period, he devoted himself principally to literary history and archæological science. The celebrated Dr Lami, with whom he had the good fortune to contract a friendship, assisted him with his counsels, and encouraged him to persevere in that path to which his genius seems to have directed him.

In the year 1747 Bandini undertook a journey to Vienna, in company with the bishop of Volterra, to whom he acted in the capacity of secretary. He was introduced to the emperor, and took the opportunity of dedicating to that monarch his *Specimen Litteraturæ Florentinæ*, which was then printing at Florence. In the following year he returned by the way of Venice, Padua, Ferrara, and Bologna, and united himself in friendship with the learned men in all these cities. Having resided some time at Florence, he repaired to Rome, and entered into orders, passing the whole of his time in the library of the Vatican, and in those of the Cardinals Passionei and Corsini. At that time the famous obelisk of Augustus was disinterred from the ruins of the *Campus Martius*. Bandini, by the order of Benedict XIV., undertook to describe and explain this curious monument; but finding that the air of Rome was injurious to his health, he returned to Florence. In 1750 he was selected by Alexander Marucelli to take charge of the valuable library which his uncle the Abbé Francis Marucelli had left, and which, according to the will of the founder, was to be open to the public. But he had scarcely entered upon the duties of this charge when the proprietor died, after bequeathing all his effects to the library, and appointing the Abbé Bandini perpetual librarian and his testamentary executor. It required two years to liquidate the succession and to form the complete catalogue of this vast library, which was at length opened to the public in the year 1752. In 1756 he was preferred by the emperor to a prebend at Florence, and appointed principal librarian to the Laurentian library. During forty-four years he continued to discharge the duties of this situation, and died in 1800, generally esteemed and regretted. On his deathbed he founded a public school, and bequeathed the remainder of his fortune to other charitable purposes. For a list of his numerous works, see *Biographie Universelle*, tom. iii. (J. C.)

BANDITTI, from the Italian *bandito*, persons proscribed, or, as we call it, outlawed, and sometimes denominated *banniti* or *toris banniti*. It is also a denomination given to highwaymen or robbers who infest roads in troops.

BANDON, or Bandonbridge, a town of Ireland, county

Bandore || Banff.

of Cork, situated on both sides of the River Bandon, which is here crossed by a bridge of six arches. It has two churches, a handsome Roman Catholic chapel, Protestant and Methodist places of worship, a convent, two market-houses, a spacious quay on the south side of the river; an infirmary, hospital, dispensary, three public libraries, two reading-rooms, two endowed schools, and a savings-bank. Its manufactures of woollen and cotton goods have much declined, but a manufacture of fine stuffs has lately sprung up; and there are also several distilleries, breweries, tanneries, and flour mills. It returns a member to parliament. Pop. (1851) 7943. By railway it is 20 miles S.W. of Cork.

BANDORE (Spanish, *bandurria*), the name of a stringed musical instrument resembling a lute, invented in the fourth year of Queen Elizabeth, by one John Rose.

BANDROL (French, *banderole*), a pennant, streamer, or little flag, in the form of a guidon, longer than broad, and usually hoisted on the masts of vessels. The term is also applied to the little silk flag that hangs on a trumpet.

BANDUSIÆ FONS, a fountain in Apulia, about six miles south of Venusia, celebrated by Horace, *Carm.* iii. 13. Some, however, suppose that this fountain is the modern *Fonte Bello*, near the poet's Sabine farm in the valley of Licenza. In the older editions of Horace it is called *Blandusia*, but in the best MS. the name is written as above. (See *Découverte de la Maison d'Horace*, by the Abbé Chaupy, vol. iii.; Obbarius's *Horace*, Jena, 1848.)

BANE, from the Saxon *bana*, a murderer, signifies destruction or overthrow. Thus, "I will be the *bane* of such a man," is a common saying; when a person receives a mortal injury by anything, we say, "it was his *bane*;" and he who is the cause of another man's death is said to be *le bane*, that is, a malefactor.

BANFF, the county town of Banffshire, is a place of great antiquity, and according to tradition, was at times the residence of Malcolm Canmore. It was in existence at least before the days of Malcolm IV., surnamed the Maiden, who dates one of his charters from thence, and it is noticed as a royalty since 1057. Writings of Malcolm, 1152, and William the Lion, 1165, evince the certainty of this tradition. There is a charter of Malcolm IV. signed at Banff the eleventh year of his reign, which corresponds with 1163. The town lost many of its ancient grants, but these were renewed in 1324 by King Robert the Bruce, and by Robert II. in 1372.

The natural situation of the town is beautiful, having its south-eastern exposure on a gentle slope, the wide blue sea on its N., the river Deveron on the E., and on the S. the richly wooded country with the magnificent mansion and grounds of the Earl of Fife. The streets are well and regularly built and paved, and are remarkable for their cleanliness.

The principal buildings are Banff Castle, a plain modern building, belonging to the Earl of Seafield; the town-house, a handsome edifice surmounted by a spire 100 feet high; a prison; parish church, Episcopal church and parsonage, Free church, United Presbyterian, Independent, Methodist, and Roman Catholic places of worship; a mason lodge of tasteful architecture; the academy, a modern edifice of Grecian design, capable of containing 400 students, to which there is attached an extensive museum; and a large and well-conducted seminary for young ladies. There are also several libraries and reading-rooms, five branch banks, and a savings-bank, public baths and hotels, custom-house, gas and water works, &c. A well-conducted newspaper, with an extensive circulation, is published weekly. At one period, Banff carried on a considerable manufactory of stockings and linen yarn, but at present there are none of any kind. It may be hoped, however, that the advantage of a commodious harbour, and the prospect of railway conveyance by the North of Scotland line, will ere long stimulate enterprise in this direction.

The principal exports are grain, cattle, salmon, herrings, haddocks, pork, butter, and potatoes. For the year ending 5th January 1853 the customs revenue of the port was L.2595. At the same date there were 144 vessels, with an aggregate of 12,689 tons, belonging to the port. Banffshire.

The salmon fishery extends for miles along the coast, a portion of which belongs to the town. The river fishing is the property of the Earl of Fife, with the sea-line towards Macduff. The latter town is about a mile to the east of Banff, with which it has communication by a stone bridge of seven arches across the Deveron.

These is also a seal and whale fishing company, with its establishment; and the steamers plying between Aberdeen, Leith, and Inverness, call regularly.

The burgh is under the jurisdiction of a provost, three bailies, and five councillors, who manage all the town's affairs. Mr Alexander Cassie of London, a native of Banff, some thirty years ago left to the poor of this town about L.20,000, the interest of which is divided twice a-year among the poor.

Banff unites with Elgin, Cullen, Inverury, Kintore, and Peterhead, in sending a member to parliament. Pop. within the parliamentary boundaries in 1851, 6000; within the municipality, 3557.

The weekly market-day is Friday, on which day a corn market is held; and there are four annual fairs.

BANFFSHIRE, a maritime county in the N.E. of Scotland, lying between Lat. 57. 6. and 57. 42. N., and Long. 2. 15. and 3. 40. N.; and bounded on the N. by the Moray Firth, E. and S. by Aberdeenshire, and W. by Morayshire and part of Inverness-shire. It has an area of 686 square miles, or 439,219 statute acres; its extent from N. to S. being 50 miles, and from E. to W. 32 miles; its average breadth not exceeding 12 miles. It contains 21 parishes, and parts of 10 others; has two royal and parliamentary burghs, Banff and Cullen; two burghs of barony, Macduff and Corncairn, in the parish of Ordiquhill; and five harbours, Banff, Cullen, Macduff, Portsoy, and Portgordon. The parliamentary burghs are contributory to Elgin, but the county returns a member to parliament. The parliamentary constituency in 1852 was 851. The parochial schoolmasters, with those of the counties of Aberdeen and Moray, share in Dick's bequest.

The surface of Banffshire presents a very diversified aspect. The lower district, which is divided from the upper by a chain of hills, is a fine open country, of a rich, deep, and highly-cultivated soil, agreeably diversified with gentle risings and young plantations. The upper district is mountainous, and at a distance wears a bleak forbidding appearance. But the scene changes on a nearer approach. Extensive farms are found embosomed in its fertile and well-cultivated glens. Some of the mountains are covered with trees in full luxuriance of growth; some presenting a beautiful intermixture of rock and copses, while others are covered with brown heath. The Spey flows along its western, and the Deveron along its eastern boundary; and both yield a considerable revenue from their salmon fishings. The principal mountains of Banffshire are Belrinnes, Knockhill, and Cairngorm, the last of which attains an elevation of 4095 feet above the level of the sea. In the lower part of the country, towards the coast, there are several elegant mansions, of which the most conspicuous are Duff House, Cullen House, Park House, Forglen House, and Gordon Castle. These, and a number of gentlemen's seats in the interior, are surrounded by extensive ornamental plantations, very tastefully laid out. The natural woods are inconsiderable both in extent and value.

The southern boundary of the county is mountainous, and is chiefly composed of gneiss and mica slate, through which granite and syenite often protrude. The granite to the eastward of Portsoy has very little mica in its composition;

the quartz assumes that letter-like form in the felspar, from which it has been termed *graphic granite*. Quartz rock appears, in the hill near Portsoy, to exist in beds, on which reposes a bed of most beautifully varied serpentine. In descending towards the coast, the primary rocks give place to graywacké-slate, which occasionally contains beds of the limestone peculiar to this formation; and these rocks are covered by the old red sandstone, which sometimes passes into quartz rock. In the graywacké near Keith, a vein of sulphuret of antimony occurs, associated with fluor spar. The bold and precipitous Troup Head, and several other parts of the coast, consist of a graywacké formation. Near Gamrie, in a bed of a bluish marly clay, are imbedded nodules of a fibrous limestone, which frequently contains fine specimens of ichthyolites or fossil fishes; of these the most remarkable species are *Cheirolepis uragus*, *Cheirocanthus Murchisoni*, and *Osteolepis arenatus*. The clay is, near the farm of Findon, about 40 feet deep, in the bottom of a ravine, the sides of which consist of old red sandstone. It extends over a considerable district; and to the westward of Banff affords many organic remains. Cudbear, or archil, a lichen used as a dye, is found growing in rocky situations.

The agriculture of Banffshire is conducted upon the newest and most approved principles. The soil, though varying even in adjacent fields, is in general rich and productive, yielding heavy crops of wheat, barley, oats, and other grain; and the grass and green crops are equally abundant. About 124,000 acres are under cultivation. The extent of the farms is in general from 150 to 200 arable acres, independently of moorland and pasture-grounds. The duration of leases is nineteen years; although there are some individuals who possess on liferent, and a few leases are held for a longer term. The whole of the farms, even the smallest pendicles, are under regular rotations of cropping, generally a five or seven course shift. The fields are well laid out and subdivided, and properly cleaned and manured; for which last purpose large quantities of lime, bone-dust, and guano, are annually imported. The ridges are all straight; and the fields, at least many of them, are inclosed with stone dykes or other fences. The swamps and wet grounds have also been drained and cultivated, so as to effect a total revolution in the ancient modes of agriculture within the county. The cattle and stock of every description are of the finest breeds which can be procured, and are sought after by the dealers at home, as well as conveyed to London, where they bring the highest prices.

This district was much indebted to one of the earls of Findlater, who, as early as the year 1754, not only introduced and exemplified on some of his own farms the most approved practices then known in England, but held out liberal encouragement to his tenants to follow his example; and his descendant, the late Earl of Seafield, did much to improve the family estates, adding to them many thousands of acres of arable land; and with truth it may be said that he was the greatest planter of trees in Great Britain within the present century. In 1846 this nobleman received the honorary gold medal of the Highland and Agricultural Society of Scotland, for his vast and thriving plantations of useful timber trees, in the counties of Banff, Moray, and Nairn. From the year 1811 to 1845, he had planted 18,938,234 Scotch firs; 11,904,798 larches; 843,450 hard woods; making the enormous aggregate of 31,686,472 forest trees, planted in 8223 acres of inclosed ground.

This county also owes much to the present Earl of Fife, by whose generous efforts, and taste for improvement, a vast amount has been done in planting and reclaiming land by favourable leases to the tenantry, and allowances for draining, &c. Green crop cultivation did not become general till after the commencement of the late war with France. Latterly, improvement has been promoted by agricultural associations, the annual premiums held out for the best specimens of live stock, and the best productions of the soil. The Banffshire Agricultural Association, which numbers about 200 members, has two shows yearly, for all sorts of stock and produce and agricultural implements, with premiums for superiority in breed of cattle, poultry, &c. The valued rental of the county is now upwards of L.150,000 sterling.

The manufactures of Banffshire are very unimportant, the inhabitants being principally engaged in agriculture and the rearing of cattle. The salmon fishery is actively prosecuted on the rivers, and the herring and other fisheries on the coast. Distilling is largely carried on in Glenlivet and other places.

Banffshire was the scene of many bloody conflicts between the Scots and their Danish invaders, but details of these encounters belong more properly to the history of Scotland. From 1624 to 1645 it was the theatre of almost incessant struggles. The Covenanting troubles of that period, combined with the frequent conflicts of the clans, were productive of serious evils. Several remains of antiquity are pointed out in different parts of the country. Of these the churches of Mortlach and Gamrie are perhaps the most remarkable. Ruins of castles and traces of encampments are often to be met with, and a great number of cairns and tumuli are also found. Among the distinguished men whom Banffshire has produced, the following may be mentioned: Archbishop Sharp of St Andrews; George Baird, distinguished for his services as sheriff of the county during the time of the Covenanters; Thomas Ruddiman the grammarian; Walter Goodall, the defender of Mary Queen of Scots; and James Ferguson the astronomer. The population of the county in 1841 and in 1851, was as follows—the apparent decrease of the number of houses in 1851 arising from stories let to different families being frequently reckoned houses in the census of 1841:—

	Houses.			Persons.		
	Inhabited.	Uninhab.	Building.	Male.	Female.	Total.
1841	11,149	474	82	23,249	26,430	49,679
1851	10,662	377	62	25,575	28,596	54,171

BANG, or Banga, the leaf of a kind of hemp or cannabis, which is used in India and in Egypt as a narcotic.

BANGALORE, a fortified town of Hindustan, in the Rajah of Mysore's territories, and a place of considerable importance during the Mussulman dynasty of Hyder Ali and his son Tippoo Sultan. In 1791 it was stormed by a force under Lord Cornwallis. Subsequently the fort, which had been constructed by Hyder in the best fashion of Mahometan architecture, was destroyed by his son Tippoo, upon finding that it was incapable of effectually resisting an assault of the British army. It was afterwards repaired in 1802. The gardens here made by Hyder and Tippoo are extensive; and owing to the elevation of the ground, the town being by observation 2901 feet above the level of the sea, European fruits and plants may be reared. During the reign of Hyder this city was populous, but was much injured by the edicts of Tippoo prohibiting all trade with the dominions of Arcot and Hyderabad, and by his forcing the merchants to buy from him a large quantity of goods at a high price. The town is well built, and has its bazaar and manufactures of silk and cotton; but its present importance arises chiefly from its being the locality of the British military establishment for the whole territory of Mysore. The distance from Seringapatam is 71 miles; from Madras 185. Lat. 12. 58. Long. 77. 38. (E. T.)

BANGKOK, the capital of Siam, stands on the banks of the river Menam, about 20 miles by water from the sea. The river is navigable to the city; but there is a bar at its mouth, which at neap ebbs has only 6 feet water on it. The river farther up is deep, though impeded by shoals and stockades. After the Burmese in 1760 took the capital Yuthia,

Bangor || Bangor-ys-coed.

the country was in a state of anarchy until a merchant of Chinese extraction put himself at the head of affairs, and made Bangkok his capital. The town extends for two miles and a half, chiefly on the east side of the river. It contains many well-built Buddhist temples, which, with their gilded pinnacles and ornamented roofs, have a good effect. On the left bank of the river are rows of floating houses. The river is nearly a quarter of a mile wide at the city. The population is believed to be from 100,000 to 150,000. The country is intersected with canals, so that the inhabitants live much on the water, especially during the annual inundations. A considerable trade is carried on with China. Except the temples and the royal palace, all the houses are of wood. Lat. 13. 58. N. Long. 100. 34. E.

BANGOR, a parliamentary borough and market town of Caernarvonshire, North Wales, nine miles N.E. of Caernarvon, to which it is a contributory borough. It consists mainly of one narrow crooked street of nearly a mile in length, stretching N.E. and S.W. through a romantic valley between two ridges of rock. It stands near the northern entrance of the Menai Strait, and the beauty of its scenery attracts many visitors, whose numbers have greatly increased since the completion of the Chester and Holyhead Railway and the Britannia tubular bridge. The principal buildings are the cathedral, Episcopal palace, deanery-house, Roman Catholic chapel, several dissenting meeting-houses, free school, union poorhouse, infirmary, market-house, assembly-rooms, temperance-hall, three banks, and railway-station. The cathedral is an embattled cruciform structure, with a low massive tower crowned with pinnacles. It occupies the site of a more ancient edifice, originally founded about 525, but destroyed by the Anglo-Normans in 1071. It was afterwards rebuilt, but suffered severely in the wars between the Welsh and Henry III.; and in 1402 it was burned down during the ravages of Owen Glyndwr. For more than ninety years it remained in ruins. The choir was rebuilt by Bishop Dean in the time of Henry VII., and the tower and nave were added by Bishop Skeffington in 1532. The principal trade of Bangor consists in the export of slates, which are raised in the quarries six miles distant, and conveyed by a railway to Port Penrhyn, at the mouth of the River Cegid, a little to the east of the town. This port is accessible for vessels of from 200 to 300 tons at all states of the tide, and has a quay upwards of 300 yards in length. Pop. of burgh in 1851, 6338.

BANGOR, a seaport and market town of Ireland, county Down, on the south side of Belfast Lough, 12 miles E.N.E. of Belfast. Pop. in 1851, 2850. It carries on a considerable cotton and linen trade, and a fishery; and has a savings-bank, market-house, a parish church, several chapels, and a public library. It is frequented as a bathing-place. Remains of an ancient abbey, said to have been destroyed by the Danes in 820, are still to be seen.

BANGOR, a seaport town in the state of Maine, North America, capital of the county of Penobscot, on the river of that name, 60 miles from the sea. Lat. 44. 47. 50. N. Long. 68. 47. W. The harbour is spacious, and affords anchorage for the largest vessels at high tide. The chief article of trade is timber. There are several good schools and a theological seminary here, and numerous churches of various denominations. Pop. 14,432.

There is another small town of this name in the state of New York, county of Franklin, 152 miles N.N.W. of Albany. Pop. 2160.

BANGOR-YS-COED, a village of North Wales, in a detached portion of Flintshire, on the Dee. Pop. 554. It was the site of one of the largest monasteries in Britain, founded before the year 180, and said to have contained in 596 no fewer than 2400 monks. Ethelfrid, king of Northumbria, in the beginning of the seventh century, massacred 1200 of these ecclesiastics, and destroyed their monastery. No traces of it are visible.

Bangorian Controversy || Banister.

BANGORIAN CONTROVERSY. See HOADLY.

BANG-PA-SOE, a fortified seaport town of Siam, situated on the left bank of the Bang-pa-Kung river, near its mouth, 39 miles E.S.E. of Bangkok. Lat. 13. 30. N. Long. 101. 11. E.

BANGUEY, an island in the Eastern Seas, lying off the north coast of Borneo. The shores abound with turtle. It is about 23 miles in length by 11 in breadth. Long. 117. 6. E. Lat. 7. 9. N.

BANIAK, an island in the Eastern Seas, off the west coast of Sumatra. It is one of a cluster of islands of the same name, and is about 17 miles in length by 7 in average breadth. The sea-slug, or *biche-de-mer*, is obtained here. Long. 96. 48. E. Lat. 2. 10. N.

BANIAN, a word used in the East to denote a Gentoo servant employed as an agent in commerce. The word is derived from the Sanscrit *banij* or *banik*, *i. e.* a merchant or trader. There is no authority for regarding the Banians as a distinct sect or caste among the inhabitants of India.

BANIAN *Tree* (*Ficus religiosa*, or *Ficus Indica*) is a native of several parts of the East Indies. It has a woody stem, branching to a great height and vast extent, with heart-shaped entire leaves terminating in acute points. Some of these trees are of amazing size and extent, as they are continually increasing, and, contrary to most other things in animal and vegetable life, seem to be exempted from decay. Every branch from the main body throws out its own roots, at first in small tender fibres, several yards from the ground; but these continually grow thicker until they reach the surface, when they strike in, increase to large trunks, and become parent trees, shooting out new branches from the top, which again in time suspend their roots, and these, swelling into trunks, produce other branches; thus continuing in a state of progression as long as the earth, the parent of them all, contributes her sustenance. On the banks of the Nerbudda stands a celebrated tree of this kind, which once covered an area so immense, that it has been known, in the march of an army, to shelter no fewer than 7000 men beneath its shade. Though now much reduced in size by the destructive power of the floods, the remainder is still near 2000 feet in circumference, measured round the principal stems, and exclusive of the spread of the branches. The Hindus have a great veneration for the banian tree, which, from its long duration, its outstretching arms, and overshadowing beneficence, they look upon as an emblem of the Deity. Near these trees the most esteemed pagodas are generally erected; under their shade the Brahmins spend their lives in religious solitude; and the natives of all castes and tribes are fond of recreating in the cool recesses, beautiful walks, and lovely vistas of this umbrageous canopy, impervious even to the direct rays of a tropical sun.

BANIAS, a town of Palestine, in the Anti-Libanus or Mount Hermon. The sources of the Jordan are about four miles N.E. of the town, now reduced to a village of 150 houses.

BANIER, ANTOINE, member of the Academy of Inscriptions and Belles-lettres, an ecclesiastic of the diocese of Clermont in Auvergne, was born in 1673. He is principally celebrated for his translation of the *Metamorphoses* of Ovid, with historical remarks and explanations; which was published in 1732 at Amsterdam, in folio, finely ornamented with copperplates by Picart, and reprinted at Paris in 1738, in 2 vols. 4to; and for his *Mythology, or Fables of the Ancients explained by History*, which was translated into English, and printed at London in 1741, in 4 vols. 8vo. He died at Paris in November 1741.

BANISTER, JOHN, a physician and surgeon in the reign of Queen Elizabeth, was educated at Oxford. In 1573 he took the degree of bachelor of physic; and obtaining a li-

Banjarmassin || Bankruptcy.

cense from the university to practise, settled at Nottingham. The time of his death is not known. His works were collected and published in 8vo and 4to in 1633.

BANJARMASSIN, a town and district of Borneo on the south-eastern coast, situated on a river of the same name, which has a shallow bar at the entrance. Lat. 3. S. Long. 114. 55. E. Many Chinese reside in this place, and carry on a considerable trade with China, exporting pepper, camphor, gold-dust, spices, wax, rattans, edible bird-nests, and biche-de-mer; and importing opium, piece-goods, coarse cutlery, gunpowder, and fire arms. In 1703 the English established a factory here; but the place was found to be extremely unhealthy, and the company's servants were finally attacked by the natives, whom they repulsed with great difficulty. The settlement was afterwards abandoned. The sultan of the district is subject to the Dutch, who established a factory here in 1848. The coal discovered in 1846 is extensively wrought by the Dutch government.

BANK, in *Political Economy*, an establishment for keeping money secure, and for dealing in money by discounting bills and otherwise. For the history of banks, see MONEY and PAPER-MONEY. That class of banks whose object is to encourage habits of saving among labourers, called banks for savings, is treated of under the head of SAVINGS-BANKS.

BANKER, a person who traffics and negotiates in money. The ancient bankers were called *argentarii* and *nummularii*; by the Greeks, *τραπεζίται*, *κολλυβισταί*, and *ἀργυραμοιβοί*. Their chief business was to put out the money of private persons to interest. They had their boards and benches for this purpose in all the markets and public places, where they took in the money from some in order to lend it to others.

BANKING, the science of a banker or dealer in money. See MONEY and PAPER-MONEY.

BANKING also denotes that branch of civil engineering which relates to the formation of banks to oppose the force of rivers, the sea, &c. See EMBANKMENT.

BANKRUPTCY, in its practical acceptation, means the arrangement by which the property of an insolvent trader or speculator is realized and distributed among his creditors according to an equitable adjustment of their claims. The term bankrupt has been derived through the Norman phraseology of English law, from the old French *banqueroute*, a word of disputed etymological origin. The term, in its earlier acceptation, involved an accusation; and the bankrupt of the old law was, according to Blackstone, "a trader who secrets himself, or does certain other acts tending to defraud his creditors." The inculpatory attribute is still retained in the law of France, where the *banqueroutier*, by coming within the penal law, is distinguished from the *failli*, or the tradesman who has become insolvent without fraud or other penal culpability.

It has been a characteristic of the laws of rude times to endeavour to trammel the extent to which legal engagements may be incurred—as, for instance, by usury laws prohibiting loans at the current or market interest of the day; while, on the other hand, they have been found to place tyrannical and exterminating remedies in the hands of creditors for enforcing such obligations as the law ordained. It seemed to be considered that there was no choice but to let the creditor exercise his will—were it to the extent of slavery or a cruel death—against the debtor unable to fulfil that obligation which the law acknowledged, and the remedies against the insolvent debtor in the twelve tables became proverbial for their sanguinary ferocity. The manner in which the conflicts between debtor and creditor in republican Rome shook the state is well known to all readers of history. It was not until the ascendancy of Julius Cæsar that a distinction is said to have been drawn between fraud and calamity, so that the debtor was released from liability to indiscriminate cruelties if he gave up all his property to those who had claims against him. It is usual, at all events, to attribute to the Lex Julia the origin of the *cessio bonorum*, or yielding up of goods—an expression still in practical use, and employed in Scotland and other countries which have inherited the civil law.

Bankruptcy.

With the rise of trade in the sixteenth century a material distinction came to be established between commercial and ordinary debtors. Perhaps the distinction, which we shall presently see to have its own peculiar justification, arose in England; and arose there not from any philosophical distinction being taken between the position of the commercial speculator and that of the ordinary debtor, but from that dislike of the civil law which made Westminster Hall reject the Roman cessio, and continue to discard it both in name and principle until the year 1826, when the first insolvent debtors' act was passed.

Nearly three centuries earlier, however, the principle of a general distribution of the debtor's goods had been at least approached as a remedy for the difficulties of mercantile men. The long line of English bankrupt statutes traces its parliamentary genealogy back to the year 1542, when an act was passed nominally intended not so much to establish a general system of realization and distribution of the property of insolvent traders, as to check certain characteristic frauds which traders were deemed to enjoy peculiar facilities for perpetrating. Thus the act (34th and 35th Hen. VIII. cap. 4) founds its remedial provisions on the preamble, "Whereas divers and sundry persons, craftily obtaining into their hands great substance of other men's goods, do suddenly flee to parts unknown, or keep their houses, not minding to pay or restore to any of their creditors their debts and duties, but at their own wills and pleasures consume the substance obtained by credit of other men, for their own pleasure and delicate living, against all reason, equity, and good conscience." Though thus directed, however, as a remedy for fraud, the statute set the precedent of a general distribution, which was more distinctly organized and assigned as an exceptional remedy against the trading classes by the act of 1570.

This being a mere remedy against frauds supposed to be peculiar to the trading class, the law of bankruptcy gradually resolved itself into a system for the speedy distribution of the effects of the insolvent trader among his creditors. While it thus changed its character from a species of penal correction and preservative against fraud, to an adjustment equally merciful to the harassed insolvent and equitable to the perplexed and discontented creditors, it retained its original peculiarity as a system applicable solely to tradesmen, and, like many other legal peculiarities which have had a fortuitous origin, this specialty has been preserved for efficient reasons.

It might appear at first that, if it be right, in the case of a tradesman in difficulties, to distribute his available effects, and enable him with his obligations discharged to start on a new race for success, it is just that all other classes of debtors should have the same privilege. It has not been usual, however, to make the privilege universal; and the following reasons may be set forth against its being so.

The true purpose of a bankrupt law is not only to release the insolvent debtor from persecuting creditors, to realize his available funds at once, and to distribute them according to an equitable adjustment among all claimants; but also to discharge the bankrupt from all subsequent legal responsibility for debts contracted before his bankruptcy. When a man is engaged in trading speculations, the justice of giving him a discharge when he yields his whole available means to his creditors, is founded on their having in some respects connived with him in his speculations, and thrown themselves on the chances of his general success. Wherever the element of credit has been admitted into trade—and there is seldom extensive trade without it—the liability of each

Bankruptcy.

associate in the circle of transactions must more or less depend on that of the others. The importer grants his bill to the producer, trusting to be able to meet it from the price of the imported commodities, and the producer who takes his bill becomes a sharer in the chances. The importer, in his turn, takes the warehouseman's bill on a similar expectation; and he in his turn receives as payment the bill of the retailer, who, knowing that he has a market for the goods, believes that he will be able to retire the bill. If, from any accidental break in the circle of credit—from the loss of a vessel, a fire, or even the failure of a trusted debtor—some one in the circle should be unable to pay his obligations, it would be cruel to leave him all his days at the mercy of every greedy or malignant man who may have had a claim against him. Thus the law of bankruptcy, after a debtor has fairly surrendered his available estate for distribution among his creditors, permits him to be discharged as if he had paid them all in full.

But, in the general case, the private debtor who purchases for consumption or possession, not to sell again, holds himself out as possessed of means to meet the obligation so incurred. At all events, he does not depend on the success of his trading with the commodity purchased by him. Hence his creditor is not a participator in a speculation, and neither directly nor indirectly looks to the debtor's chances of success for payment. In the general case, when such a debtor finds himself unable to pay his debts, his difficulties arise from wilful extravagance, or careless miscalculation; and excepting, perhaps, the too great credulity of creditors, he has no one's conduct to blame but his own. The humanity of the later English law provides for the immediate relief from execution against person or property of all persons who become embarrassed without fraud or excessive recklessness. But there is this general distinction,—and it has been the object of the preceding remarks to make it the more emphatically distinct,—that such debtors do not obtain their discharge from all obligations, which is the closing scene of a mercantile bankruptcy. If debtors not connected with trade could thus effect, when plunged into the lowest depths of insolvency, a complete release from all their obligations, we would have the spendthrift passing through the ordeal before the opening of his succession to an estate, and laughing at the creditors, of whom he is as much as ever he was morally, though he may not be legally, the debtor.

The defect of the English system, undoubtedly, was to make the distinction too broad, and, while a code of bankruptcy had been gradually reared up for the distribution of traders' estates, to leave the ordinary class of debtors to the mercy of their creditors until the jails, becoming choked, were from time to time emptied by those legal protests against the inhumanity of the law, the acts for the relief of insolvent debtors. A permanent measure for dealing with insolvents not in trade was at last adopted, and an account of it will be found under the head of insolvency. It is chiefly of importance here from its preserving the principle, that the debtor not in trade, however he may be protected from execution, is not to be relieved from his obligations, should he afterwards obtain property which might be applied to them. The commissioners appointed to inquire into the state of the law of bankruptcy and insolvency, who reported in 1840, said—

"The immediate object of the bankrupt law is the equal distribution of the effects of traders who cannot meet their engagements—its ordinary consequence, the release of such traders from all future liability of their persons and after acquired property.

"The object of the law for the relief of insolvent debtors is the personal discharge of honest debtors, prolonged imprisonment by way of punishment for the dishonest and fraudulent, and a fair distribution of their present effects, and future acquired property, among their creditors."

The availability of the future acquired property is thus the peculiar responsibility from which the trader is exempt. Perhaps the line is sometimes arbitrarily drawn, excluding some who ought to be included in the class, entitled at once to clear themselves of responsibility for past debts. That the definitions of the bankrupt acts have never cut clean, has been shown by the crowds of persons who have been admitted within the definitions of trading persons contained in them, without having been intentionally or definitely included. Still the existence of a distinction between dischargeable and undischargeable insolvents is fundamental to the bankruptcy system of the great trading nations, although there is probably a tendency to modify the difference between them. Thus in England, the measure of 1844, called "An Act for facilitating arrangements between Debtors and Creditors" (7th and 8th Vict. cap. 70), provides for the discharge of insolvents, though not in trade, if they have a certain amount of concurrence from their creditors. The insolvent must have the concurrence of a third of his creditors (calculated both by number and value) to the initial steps; and to conduct his discharge he must not only have certain proportional consents at a preliminary meeting, but at the conclusive meeting must have the votes of three-fifths in number and value, or of nine-tenths in value, or of nine-tenths of those whose debts exceed L.20. In the general bankruptcy act passed by congress in 1841 for the United States, there was a large extension of the old privileges of bankruptcy to classes of persons not in trade; and it has been stated that this was the main reason for the repeal of the act in 1843, which left the United States without any general system of bankruptcy law.

Bankruptcy.

The classes of persons subject to the bankrupt law in England have been enlarged from time to time by successive statutes. The conditions of circumstances called "acts of bankruptcy," which bring a trader within the operation of the law, have also been more fully defined from time to time. Some standard definitions have, however, been always religiously preserved from the old acts, because they possess not only their natural meaning as English sentences, but carry with them the whole substantive law of a long series of decisions, fixing their application to practical life and business. Hence, these definitions are ever terse and distinct, enabling one section of the bankrupt act to contain more law than all the others. Thus, each event is briefly described in a series of sentences like these: "If any such trader shall depart this realm, or being out of this realm, shall remain abroad or depart from his dwelling-house, or otherwise absent himself, or suffer himself to be arrested for any debt not due," &c., has an extensive practical meaning in law; and it is only to be regretted, that while great power and precision are imparted to these brief definitions by the proceedings of the courts of law for more than 200 years, the definitions, so pregnant with meaning to practical lawyers, convey little or no information to the rest of the world.

A rapid series of reforms in the English bankruptcy law began at the conclusion of the first quarter of the present century, and it may be questioned if they are yet concluded. The act of 1825 (6th Geo. IV. cap. 16) gathered up all the stray improvements which had been for some time scattered through the statute-book, and consolidated them with some new and significant alterations. It contained the fruit of Sir Samuel Romilly's enlightened speculations, and in furtherance of his suggestions, made provision for proving or adjusting the claims of annuitants and persons who were not immediate, but merely contingent creditors; both of them classes whose admission to a claim on the estate required the operation of the law of chances. A novelty in the law of England was introduced by this act, from the practice long known in Scotland as the "composition contract," by which the sanction of the bankrupt law is given to an engagement on the part of the bankrupt to pay, and on the

Bankruptcy.

part of his creditors, to accept in full, a certain sum as a single and final dividend.

A great revolution both in the judicial and administrative department of the bankrupt law was begun by Lord Brougham's Act of 1831 (1st and 2d Will. IV. cap. 56). One of its main features was the establishment of a separate tribunal in bankruptcy, and the substitution of a "fiat" instead of the old "commission" issuing from the Court of Chancery. Another great feature in this measure was the appointment of "official assignees" in connection with the court of bankruptcy, who as neutral stipendiary officers have charge of the property immediately on the bankruptcy, and see to its fair distribution among the creditors; while the "chosen assignee" in each estate, as the general representative of the creditors, finds it his function to make the estate collectively large, without reference to its division. The bankruptcy laws of England were consolidated in 1849, in an act consisting of 278 sections (12th and 13th Vict. cap. 106). Again there was a change in the essential nomenclature. The "fiat" was superseded, an "adjudication" substituted for it, and the relations of matters in order of time, of which the fiat was the criterion, came to be considered in relation to the petition for adjudication. Another and highly important arrangement completes a series of changes by which judicial inquiry and decision on the conduct of the bankrupt have gradually superseded the arbitrary votes of the creditors for treating him according as they might deem fitting, from the influence of his conduct on their feelings or opinions. A public sitting is held on the allowance of the certificate, and the commissioner there hears creditors, giving weight to their statements and pleadings, but not acting under their votes. Should no creditors give opposition, there is still to be inquiry, "and the court having regard to the conformity of the bankrupt to the law of bankruptcy, and to his conduct as a trader before as well as after his bankruptcy, and whether the allowance of such certificate be opposed by any creditor or not, shall judge of any objection against allowing such certificate, and either find the bankrupt entitled thereto and allow the same, or refuse or suspend the allowance thereof, or annex such conditions thereto as the justice of the case may require." The form of the certificate is calculated for still more emphatically bringing out this judicial determination of the bankrupt's moral rank, by dividing certificates into three classes, first, second, and third. The alternatives are, "and I farther certify that his bankruptcy has arisen from unavoidable losses and misfortunes, and that he is entitled to, and I do award him, this certificate as of the first class; *or* that his bankruptcy has not wholly arisen from unavoidable losses and misfortunes, and that he is entitled to, and I do award him, this certificate as of the second class; *or* that his bankruptcy has not arisen from unavoidable losses or misfortunes, and that he is only entitled to, and I do only award him, this certificate as of the third class."

This arrangement, adding to the judicial function of deciding on particular disputed points, that of fixing the character and position in life of the citizen, has not been long enough in force to let its effect be fully appreciated. From a return to the House of Lords in May 1853 of the number of certificates granted to bankrupts since the Consolidation Act of 1849, it appears that of a total number of 1513 certificates which had then been granted, 416 were *first*, 719 *second*, and 378 *third* class certificates. There is said, however, to be much difference of opinion among the commissioners as to the principle on which bankrupts should be classified; the first-class certificate being in many of the country districts given as a matter of course in all ordinary cases, while in London, certificates of the third-class have been awarded in ordinary cases, without any intention of conveying reflection or censure.

The establishment of the court of bankruptcy consists of two lords justices, with five London commissioners, and separate district commissioners in Manchester, Liverpool, Birmingham, Leeds, Bristol, Exeter, and Newcastle. There are ten official assignees in London, and two or more in each district, and the court has an accountant with a staff of registrars, clerks, and other subordinate officers.

Bankruptcy.

The main objects to which the vast amount of late legislation on bankruptcy has been directed, are the instantaneous adjudication and publication of the debtor's condition as a bankrupt at the moment when this becomes properly necessary, the equally instantaneous or immediate transference of all his property into impartial and responsible hands, the effective management of the property, its conversion into cash with the greatest practicable rapidity, the detection, exposure, and, in flagrant cases, the punishment of any attempts by the bankrupt to conceal or withdraw property, or unduly to favour particular claimants, a rapid and impartial distribution of the funds, and finally, the restoration of the bankrupt to society, with a character in the commercial world adjusted to that of his conduct towards his creditors. It is still a matter of complaint, that if these objects be effected it is in a very costly manner, and that the multitudinous fees incurred sweep away the greater part of the estate in petty bankruptcies. The adoption of official assignees appears to have been the only measure which has met with unqualified approbation in the commercial classes, and in a "Paper of Observations" laid before the House of Lords in 1853, in relation to a bill for extending the system to Scotland, the value of a control over elected assignees or trustees is shown in the statement, that "these new public officers commenced their useful career under the able superintendence of the commissioners, by recovering, as they were empowered by the act, very large sums of money, amounting to four millions sterling, from the former assignees under old bankruptcies. For two millions and a half of that sum the official assignees found rightful owners; one million and a half nearly for which no owners can be found remain in the bank of England invested in three per cent. consols, and yielding about L.45,000 a-year."

The Irish bankruptcy system has been modelled on that of England, the changes of which it has followed from time to time. It was in the year 1771 that the system was first extended to that country, and the Irish statute importing it (11th and 12th Geo. III. cap. 8) is an exact repetition of the sections of various English statutes. It has been followed by several successive acts, and all were consolidated in 1849 by a measure immediately following the English act in the statute-book (12th and 13th Vict. cap. 107). There were formerly thirty commissioners to Ireland, but in 1836 one salaried commissioner was appointed, and another was added soon afterwards. The old phraseology is returned to, the lord chancellor issuing a commission, and there are two official assignees. The provisions for carrying out arrangements with their creditors by debtors who are not traders according to the English act of 1844, are incorporated in the body of the measure, and this seems to have created a doubt whether, since they are a portion of an act strictly applicable to traders, they can be construed to include the class of debtors for whom they were after the example of the English act designed (see Clements *On the Law of Bankruptcy in Ireland*, p. 162). In the Irish act the distinction of certificates into three classes according to the later English arrangements has not been followed.

In Scotland the bankruptcy system, with the same general object as that of England, has a totally different machinery and nomenclature. That arrangement for the collection and distribution of a trader's insolvent estate, which in England receives the name of bankruptcy, is there called "sequestration;" and the term "bankrupt"—which, to have a proper legal signification, has the prefix "notour," or notorious—is comprehensively applied to persons, whether traders or not, whose insolvency has been rendered distinct and public, by

Bankruptcy.

legal steps for the enforcement of debts having advanced against them to a certain point—for instance, by a writ having been issued for imprisonment, or a permament attachment having been laid on property or effects. The earliest arrangement for something like an equitable adjustment of the claims of conflicting creditors was a feature of the judicious policy of the revolution settlement, and dates from the year 1691. A system, however, peculiarly adapted, like that of England, to the estates of traders, was not adopted until the year 1772; and, as it is obviously easier to enlarge than to contract the influence of legal nomenclature, it was necessary to abandon the use of the word "bankruptcy," already possessed of a broader signification, and to confer on the narrower word "sequestration" a new and wider meaning coextensive with the operation of the act. The sequestration system was revised in 1814 (54th Geo. III. cap. 137), and again in 1839 (2d and 3d Vict. cap. 42). The act of 1839 is the leading sequestration act, though some of its operative clauses were altered by a third act in the year 1853 (16th and 17th Vict. cap. 53). The chief object of the amending act was to abbreviate the procedure, so that when the arrangements are satisfactorily conducted, the payment of the first dividend and the bankrupt's discharge may take place in six months from the date of the sequestration. So far as it applies to living debtors, the sequestration, like the English bankruptcy, attaches only the estates of traders or speculators; but, by the act of 1839, the estates of a deceased person may be sequestrated without reference to his occupation, and the process has been frequently adopted as a method of distributing estates liable to complicated claims.

The sequestration issues from the Court of Session, whence it is remitted to the sheriff of the county, who to some extent fulfils the functions of the English commissioner. The system of official assignees is unknown in Scotland. The estate passes first into the hands of the "interim factor," and next into those of the "trustee," who acts in the double capacity of administrator of the property, and judge in the first instance of the claims of the individual creditors. The interim factor, who was formerly elected, is by the act of 1853 judicially nominated. The trustee is still chosen by the creditors. His election often occasions a keen contest, and the reports of decisions in the Court of Session show many instances in which such competitions are fruitful in litigation. The battle-ground of such a question is generally on the qualification of a creditor to give the vote which he has offered. It may be objected by the supporters of the opposing candidate, that the debt set forth is not a sufficient qualification for the vote, or that if it may be in itself a foundation for a vote, the statutory requisites have not been complied with in the method of stating it. It appears to have been the fundamental design of the system, that if a creditor complied with certain simple formalities and swore to his debt, he was to be admitted as a creditor for the preliminary operation of a vote, however baseless his debts might afterwards turn out to be in the fuller inquiry necessary to entitle him to a dividend. Creditors were thus to be taken at their word for the privilege of voting, provided they complied with the proper formalities. But whatever may have been the design of the founders of the system, the keenness of the aspirants for the office of trustee, and the practice of the courts of law, have together made the competitions little clusters of litigation about the debts of all the creditors who may have voted. In the act of 1853 the litigation is at all events limited to the inferior courts, and there are provisions intended to render the forms of claims less complex. A feeling has however arisen, especially among creditors out of Scotland, that the eagerness of these contests points to objects inconsistent with the impartial administration of the estate, and especially to the interests of distant creditors who cannot easily take a part in them; and it is maintained that such powers as those possessed by the trustee ought not to be committed to an officer who owes his election to the superior influence or tactics of a party among the creditors.

Banks.

On this and other grounds, there have lately been very urgent demands on the part of English merchants for a fundamental alteration of the Scottish sequestration law, and its closer adaptation to the English system; and a bill to accomplish this object was, at their instance, introduced by Lord Brougham in 1853. Undoubtedly there is no branch of the law where, on account of the universality of its influence, international uniformity is more important, nor is there any where it is more easily obtained, since the whole system is statutory and administrational, and has been subject to many changes in either end of the island. In England the nomenclature has been so frequently altered, that what was formerly a "commission" was lately a "fiat," and is now a "petition and adjudication," while the same thing in Scotland is called the "interlocutor awarding sequestration." There is much essential confusion in the totally different meaning of the word bankrupt in the two countries, and besides other nominal differences, such as that of "assignee," and "trustee;" what is termed "proving" a debt in England is called "ranking" it in Scotland, and the "certificate" of a bankrupt is called the "discharge" in a sequestration.

Almost every civilized country in the world possesses its code of bankruptcy, directed with more or less fulness to the objects which have been described as the aim of our own systems. In France a new bankruptcy law was inserted into the code of commerce in the year 1838. One fundamental peculiarity of the system there has been already referred to. The possession of a tribunal of commerce at the head of this, as of other departments of the mercantile law, is another peculiarity of the organization in that country. The *faillite* is declared by the court on the declaration which an insolvent stopping payment is bound to make to the registrar, on application by creditors as in this country, or *proprio motu* of the court itself. The court appoints one of its own members judge-commissioner, to perform functions corresponding with those of the official assignee in England. Another officer called the syndic, who is compared to the English trade assignee, is also appointed by the court, whence all the operations in the French system issue. The creditors collectively have no selection of officers, but they have, as in Britain, certain powers of general action for their common interests, as by adopting a concordat with the debtor, authorizing the business to be carried on, and the like. The portions of the code relating to this head have been made accessible to the English reader in a little work called *The Law of France in relation to Insolvency and Bankruptcy, &c.*, by Richard Miller, 1853. It has been mentioned above that a general bankruptcy system adopted by congress for the United States in 1841 was repealed in 1843, and each state in the union has now its own system. (J. H. B.)

BANKS, John, a dramatic writer in the time of Queen Anne, was bred to the law, and belonged to the society of Gray's Inn; but he early quitted the study of the law for the service of the muses. He wrote several tragedies, which, though evincing considerable pathetic powers, have otherwise no great literary merit. One of these, the *Albion Queens*, was acted, by Queen Anne's command, in 1706.

Banks, *Sir Joseph*, for upwards of forty years the distinguished president of the Royal Society of London, was born in Argyle Street, London, on the 13th of February 1743. He was the only son of Mr William Banks, a gentleman of considerable landed property, whose father had derived his fortune principally from successful practice as a physician in Lincolnshire, who had on one occasion been sheriff of that county, and had for some years represented Peterborough in parliament. The family was

Banks, Sir Joseph.

originally Swedish, though it had for several generations been settled in England.

Very few particulars are known respecting the early life of Mr Banks, which was passed principally at Revesby hall, the seat of his father, in Lincolnshire. His education was for some years intrusted to a private tutor. He was afterwards sent to Harrow school, and thence was removed to Christ's College, Oxford. He there made considerable proficiency in classical knowledge, but evinced at the same time a very decided predilection for the pursuits of natural history. Botany, in particular, was the favourite occupation of his leisure hours. The character of Linnæus excited his admiration; and the fame of that illustrious naturalist presenting itself to his youthful mind as the noblest object of emulation, he devoted himself with enthusiastic ardour and perseverance to the cultivation of that fascinating science. An anecdote is told of his being, on one occasion, so intent in exploring ditches and secluded spots in search of rare plants, as to have excited the suspicions of some countrymen, who, conceiving that he could have no innocent design, surprised him one day, while he lay asleep, exhausted with fatigue, and brought him as a thief before a magistrate, by whom, however, he was, after a strict investigation, soon liberated; but the incident occasioned much amusement in the neighbourhood.

At the age of eighteen he lost his father, and thus succeeded to an ample inheritance at a period of life when the attractions of pleasure too often operate with irresistible force. His attachments to science and to intellectual enjoyments were fortunately sufficiently powerful to enable him to resist the fascination; and the noble bent of his ambition was happily fostered by the judicious conduct of his mother, who added the effectual motive of her encouragement, and gave the best direction to his youthful energy.

Soon after the death of her husband, Mrs Banks removed with her family, consisting of her son and daughter, from Lincolnshire, and was induced to fix her residence at Chelsea, as a spot affording peculiar advantages for the pursuit of botany, in consequence of the numerous gardens in the vicinity, appropriated to the cultivation of curious plants of every description. The garden of Sir Hans Sloane, bequeathed by him to the company of apothecaries of London, was among the number; and this, as well as the Chelsea Botanic Garden, and various nursery grounds in the neighbourhood, furnished our student with abundance of objects of research.

It was about this period that he formed an acquaintance with Lord Sandwich, contracted while enjoying together the recreation of angling, of which they were both equally fond. To the friendship of this nobleman, afterwards appointed first lord of the admiralty, Mr Banks was, in the course of his life, indebted for essential aid in the furtherance of his numerous projects for the advancement of scientific knowledge. Mr Banks was no sooner of age than he quitted the university, and undertook a voyage to Newfoundland and the Labrador coast, for the purpose of exploring the botany of those unfrequented regions, and brought home from thence valuable collections, not merely of plants, but also of insects and other natural productions. Subsequently, through the interest of Lord Sandwich, then at the head of the admiralty, he obtained from government leave to embark in the ship commanded by the great navigator Captain Cook, who had been commissioned to observe the transit of Venus in the Pacific Ocean, and to fulfil also the usual objects of a general voyage of discovery. The preparations made by Mr Banks for turning to the best account the opportunities that might present themselves during the voyage were commensurate with the magnitude of the undertaking. He provided himself with the best instruments for making all kinds of observations, and for preserving specimens of natural history. He prevailed upon Dr Solander, a distinguished pupil of Linnæus, who had lately become resident in England, and was zealously devoted to the pursuits of science, to become his associate in this enterprise. He engaged draftsmen and painters to delineate all objects of interest that did not admit of being transported or preserved; and also other persons whose services might in various ways be wanted in the execution of his designs.

Banks, Sir Joseph

The time we are speaking of forms a remarkable epoch in the history of science, as being that in which several contemporaneous expeditions for the promotion of scientific knowledge were made by the direction of the leading sovereigns of Europe. The one intrusted to Captain Cook had for its object the alliance of navigation with astronomy, from which the nation has since reaped such important advantages. This was also the time when the empress Catharine of Russia ordered extensive expeditions in Siberia under the direction of the celebrated Pallas, the primary object of which was also the observation of the transit of Venus in that part of the world, but which gave occasion to the great advancement of natural history, and the acquisition of magnificent collections of specimens. It was also at this period that Bougainville was, by command of Louis XV., circumnavigating the globe, accompanied by Commerson, to whom science is indebted for such rich accessions of knowledge. But not the least among the valuable fruits of these researches has been the lesson they have imparted to mankind, how much more imperishable is the glory that redounds to princes and to nations from such conquests in the unexplored regions of science, than from the unprincipled extensions of empire or the barbarous triumphs of the sword.

The voyages of Captain Cook, and the interesting discoveries that accrued from them, have so long been justly esteemed an important accession to the fame of our country, that a portion of that reputation must be allowed to descend to all those whose exertions contributed to their success. Of this merit a considerable share must be adjudged to Mr Banks, who brought home a splendid collection of specimens, more particularly from Otaheite, New Zealand, and Australia.

This voyage occupied three years of the life of Banks; and no sooner was he returned from it than, with unabated ardour, we find him eager to undertake another of equal extent. He had engaged his passage in the second expedition under Captain Cook, and had made all the necessary preparations for embarking, when he was suddenly obliged to relinquish his design in consequence of the conduct of Sir Hugh Palliser, who, he discovered, had been using all his influence with the admiralty to thwart his views, and frustrate the accomplishment of all his objects. It is due to the memory of Cook to state, that he took no part in this intrigue, but expressed his uniform friendship for Banks, and his deep regret at being deprived of his able co-operation. Disappointed in his hopes, Mr Banks immediately directed his efforts to the equipment of a ship at his own expense; and taking with him Dr Solander, Dr Lind, Von Troil, a Swedish naturalist, and others, who were to have been his companions in the second expedition with Captain Cook, he sailed for Iceland in July 1772; and after exploring, during two months, that interesting region of volcanoes, he returned enriched with valuable specimens and still more valuable information respecting its productions.

The island of Staffa, the existence of which was at that period scarcely known beyond the immediate neighbour-

Banks, Sir Joseph.

hood, was visited by our travellers on their way to Iceland, and its extraordinary groups of basaltic columns attracted much of their attention. The account of these, together with the drawings taken on the spot, was liberally communicated by Mr Banks to Pennant, for publication among his works. The information relating to Iceland was given to the world by M. Von Troil, who was afterwards appointed bishop of Linkioping.

But a great part of the knowledge resulting from the various travels of Mr Banks was communicated by him, from time to time, in papers to the Royal Society of London, of which he had been elected a fellow in the year 1766, and admitted in the following year, previous to his voyage with Captain Cook. He was a constant attendant on the meetings of that society, and took a very active part in its proceedings. On the resignation of Sir John Pringle, in the year 1778, Mr Banks was elected president of the Royal Society, an honour which he continued to enjoy till his death. A fierce dispute having arisen respecting the superiority of pointed over blunt conductors for lightning, it would appear that Sir John Pringle had the ill fortune to differ in opinion from the men then in power at court, who, to flatter the prejudices of the sovereign, arrayed themselves in opposition to the discoveries of Franklin, which, emanating from America, were supposed to have necessarily a revolutionary character. It was in vain that the honest president of the Royal Society made an humble representation that the prerogatives of his office did not extend to the control of the laws of nature; superior influence compelled him to retire from a situation which he could not retain with honour amidst the angry passions called forth during these philosophical polemics. His successor was more fortunate, and enjoyed during his whole life the favour of the court; in proof of which the title of baronet was conferred upon him in the year 1781. In 1795 Sir Joseph Banks obtained also from his majesty the order of the bath; and in 1797 he was appointed a member of the privy council. It does not appear, however, that he mingled much in politics, though he occasionally gave his opinion, when consulted on such questions of public interest as involved subjects of science. But to the honour of Sir Joseph Banks it ought certainly to be recorded, that, whilst he was unremitting in his solicitude to retain the full influence he enjoyed with those in power, he never made that influence subservient to the purposes of a selfish ambition, and invariably exerted it for the promotion of scientific objects, and the encouragement of those who pursued them. He made the most generous use of his library and collections, which were always open to every inquirer of respectability. His ample fortune enabled him to supply pecuniary assistance to useful works and enterprises; and, what was often as effectually serviceable, he freely gave to those who sought it the benefit of his counsel and experience.

As proofs of the unreserved manner in which he communicated the scientific treasures he had amassed to those capable of making a proper use of them, many works on natural history may be mentioned which have been enriched by the information derived from these collections, and which even owe their existence to the encouragement thus afforded to their authors. It was by their aid that the celebrated Fabricius was enabled to prosecute his extensive entomological researches. Broussonnet availed himself largely of Sir Joseph Banks's specimens of fishes for his work on ichthyology. Botanists, in particular, derived the greatest assistance from the stores of his herbarium. From this source it was that Gærtner obtained the most valuable materials for his excellent history of fruits and seeds. The admirable work of Mr Robert Brown, *On the Plants of New Holland*, was conducted under the immediate eye of Sir Joseph Banks, and with the aid of the materials derived from his collections.

Banks, Sir Joseph.

Sir Joseph Banks evinced an anxiety to diffuse over each region of the globe the productions of other climates. Thus he brought into Europe the seeds of the plants of the South Sea Islands, as he had already distributed to the latter those of Europe. We are indebted to his exertions for many of the beautiful plants which adorn our gardens and shrubberies. The sugar-cane of Otaheite was by him transplanted into the colonies; and the bread-fruit tree of the Pacific was introduced into the tropical soil of America, destined perhaps to repay in a future age to its inhabitants the benefits we ourselves have derived from the potato they formerly furnished. The flax brought from New Zealand, superior in many of its qualities to that of Europe, is among the presents he has made us. The black swan and the kangaroo are among the animals from Australia, for the introduction of which into this country we are indebted to Sir Joseph Banks.

The establishment of the British colony in New South Wales was one of the results of the expedition of Captain Cook, to which the exertions of Sir Joseph Banks mainly contributed; and who will venture to predict the important consequences this event may have on the future destinies of that vast continent of which it forms a part?

At the commencement of the American war the French king, Louis XVI., had issued general orders to his officers in all parts of the world, to offer no molestation to the vessels engaged in the expedition of discovery under Captain Cook, but, on the contrary, to furnish them with every requisite assistance in the prosecution of their objects. Sir Joseph Banks, in the spirit of generous reciprocity, exerted himself successfully to obtain, that a perpetual immunity from the evils of war for those engaged in scientific enterprises should be recognised, as it now is, as one of the laws of civilized warfare. This virtuous principle, which forms an honourable exception to the demoralizing tendency of national animosities, was adhered to in the case of the expedition of La Pérouse, orders being sent by the British government, in time of war, to make every inquiry respecting the fate of that unfortunate navigator, and supply every aid that might be required, in case the survivors should be discovered. After the disastrous termination of the expedition under D'Entrecasteaux, the collection of Labillardière being captured and brought to England, Sir Joseph Banks exerted himself successfully to obtain its release and delivery, untouched, to the French government. His motive for abstaining from the inspection of its contents was, as he expressed in a letter to Jussieu, lest any part of that knowledge, to the acquisition of which so eminent a botanist had devoted the best years of his life, should become alienated from its rightful owner. On ten different occasions collections addressed to the National Museums of Paris, and captured by British privateers, were in like manner restored and forwarded to their proper destination.

Sir Joseph Banks continued to fill the honourable office of president of the Royal Society, the just reward of his ardent zeal and unwearied exertions in the cause of science, for a period of more than forty years; enjoying the correspondence and confidence of most of the distinguished men of learning of this and other nations. His name was enrolled amongst the associates of almost every academy and learned society in Europe. His house and his table were ever open for the reception and entertainment of the leading members of the Royal Society, and of foreigners eminent for their scientific attainments, with that spirit of liberality which is so conducive to the union of interests and co-operation of efforts requisite for the successful cultivation of knowledge. The want of such a

centre of union has often led to the destruction of that harmony which should ever characterize men engaged in a common pursuit, calculated to raise them above vulgar passions; and the want of such harmony has always proved highly detrimental to the interests of science.

Notwithstanding the liberality that marked the conduct of Sir Joseph Banks in his intercourse with men of science of all countries, he had many bitter enemies; and his memory, soon after his death, was assailed by virulent invective. Yet his name will ever be remembered with gratitude by the friends of science, whom he benefited while living, and for whose use he bequeathed to the British Museum his books and botanical collections, under the care of that most distinguished botanist Mr Robert Brown. It is, however, not a little singular that, among the whole of his bequests, there is not one in favour of that society over which he had presided for above forty years, and from his connection with which he derived so much of the lustre which encompassed him; it would almost seem, indeed, as if he wished to be forgotten by them, since there is not a single syllable in his will expressive of his own recollection of that society.

Sir Joseph Banks was married, but had no family. During many of the latter years of his life he was a great sufferer from the gout, which almost totally deprived him of the use of his feet and legs. He died at his house in Soho Square, on the 19th of March 1820, at the age of 77. He was succeeded in the chair of the Royal Society for the remainder of the year by Dr Wollaston, and, at the ensuing anniversary, by Sir Humphry Davy, names that will ever remain illustrious in the annals of science. The only authentic particulars that have been yet published respecting the life of Sir Joseph Banks are contained in the *Éloge* by Cuvier, which was read to the Royal Academy of Sciences at Paris on the 2d of April 1821, and published in the fifth volume of the *Memoirs* of that academy. (P. M. R.)

BANKS, *Thomas*, an English sculptor, whose fame rests chiefly on his "Caractacus taken prisoner to Rome;" "Achilles mourning the loss of Briseïs;" and the monument to the memory of Sir Eyre Coote in Westminster Abbey. He died in 1805, at the age of 70. See SCULPTURE.

BANKS'S ISLAND, an island of New Zealand, of a circular form, about 60 miles in circumference, and visible at the distance of 12 or 15 leagues. It is of a broken irregular surface, and presents a barren appearance, though it is inhabited. It is 15 miles from Tavai-Poenammoo. The south point lies in Long. 186. 30. W. Lat. 43. 32. S.

BANN, a considerable river of Ireland, rising in the Mourne Mountains, traversing Lough Neagh, and flowing into the Atlantic. It is commonly described as two rivers separated by Lough Neagh. The upper Bann has a N.W. course from its source to Lough Neagh, and is navigable for vessels of 50 tons to its junction with the Newry canal, a little above Portadown. The lower flows in a northern direction, and is navigable up to Coleraine for vessels of 200 tons; but the bar at its mouth renders it difficult of access in rough weather. Measured in a direct line, the upper Bann is about 35 miles long, and the lower 30 miles.

BANNER, denotes either a square flag, or the principal standard of a prince or state. We find a multiplicity of opinions concerning the etymology of the word *banner*; some deriving it from the Latin *bandum*, a band or flag; others from the word *bann*, to summon the vassals to appear in arms; others, again, from the German *ban*, a field or tenement, because landed men alone were allowed a banner; and finally, there are persons who think it a corruption of *pannière*, from *pannus*, cloth, because banners were originally made of cloth.

BANNERETS, an ancient order of knights, or feudal lords, who led their vassals to battle under their own flag or banner, when summoned by the king. Bannerets are also called by ancient writers *milites vexilliferi*, and *vexillarii banerarii, bannarii, banderisii*, &c.

Anciently there were two kinds of knights, *great* and *little*; the first, called *bannerets*, composed of the upper, and the second, called *bachelors*, of the middle nobility. The banneret was allowed to march under his own flag, whereas the *bachelarius eques* followed that of another.

Banneret, according to Spelman, was a middle order between a baron and a simple knight. Hence he was sometimes callen *vexillarius minor*, to distinguish him from the greater, that is, from the baron, to whom alone properly belonged *jus vexilli*, or privilege of the square flag. Hence the banneret was also called *bannerettus, quasi baro minor*; a word frequently used by English writers in the same sense as banneret was by the French, though neither of them occur before the time of Edward II.

Some are of opinion that bannerets were originally persons who had a portion of a barony assigned them, and enjoyed it under the title of *baro proximus*, with the same prerogatives as the baron himself. Others, again, find the origin of bannerets in France, in Britanny, or in England; attributing the institution to Conan, lieutenant of Maximus, who revolted with the Roman legions in England, and deprived Gratian of the empire, A. D. 383. According to them, he divided England into forty cantons, and among these cantons distributed forty knights, to whom he gave power of assembling, on occasion, under their several banners, as many effective men as were to be found in their respective districts; whence they are called *bannerets*. It appears, however, from Froissart and others that, anciently, such of the military men as were rich enough to raise and subsist a company of armed men, and had a right to do so, were called *bannerets*; not, however, that these qualifications rendered them knights; they were only bannerets, and the appellation of knight was added because they were simple knights before.

Bannerets were second to none but knights of the garter. They were reputed the next degree below the nobility, and were allowed to bear arms with supporters. In France, it is said, the dignity was hereditary; but in England it died with the person who gained it. On the institution of baronets by King James I. the order dwindled, and at length became extinct. The last banneret created was Sir John Smith, who received the dignity after Edgehill fight, for his gallantry in rescuing the standard of Charles I.

BANNISTER, JOHN, one of the most eminent comedians of the British stage, was born in London in 1760. After a distinguished and honourable career, in 1815 he left the stage, and enjoyed in his retirement the esteem and admiration of all who had the pleasure of his acquaintance. His death took place on the 8th November 1836.

BANNOCKBURN, a village of Scotland, on the Bannock, an affluent of the Forth, three miles south of Stirling. In 1851, its population amounted to 2627, principally employed in the manufacture of tartans and carpets. Here, on the 24th of June 1314, was fought the memorable battle of Bannockburn, which secured the independence of Scotland, and established Bruce upon the throne. A fragment of the "bore stone" in which the royal standard was placed, is still to be seen, protected from the depredations of strangers by an iron frame-work. At Sauchieburn, in the neighbourhood, James III. was defeated by his subjects in 1488. See SCOTLAND.

BANQUETING ROOM or HOUSE. The ancient Romans supped in the *atrium*, or vestibule, of their houses; but in after-times magnificent saloons or banqueting-rooms were built, for the more commodious and splendid entertainment of their guests. Lucullus had several of these, each distinguished by the name of some god; and there was a particular rate of expense appropriated to each. Plutarch relates with

Bantam ‖ Bapaume.

what magnificence he entertained Cicero and Pompey, who went with a design to surprise him, by only telling a slave who waited, that the cloth should be laid in the Apollo. The Emperor Claudius, among others, had a splendid banqueting-room named Mercury. But everything of this kind was outdone by the lustre of the celebrated banqueting-house of Nero, called *domus aurea*, which, by the circular motion of its partitions and ceilings, imitated the revolution of the heavens, representing the different seasons of the year, which changed at every service, and showered down flowers, essences, and perfumes, on the guests.

BANTAM, a decayed town of Java, formerly capital of a district of the same name, at the north-western extremity of the island, situated on the Bay of Bantam, near the mouth of a river which falls into the bay. It was once a large, rich, and flourishing city, but now exhibits nothing except ruins, the memorials of its departed greatness. It is about 61 miles west from Batavia, and is situated on a low, swampy beach, surrounded by jungle, and intersected with stagnant streams, so that its climate is even more unhealthy than that of Batavia. After Batavia surrendered to the British arms in 1811, this kingdom was in a state of great distraction. the British government of Batavia accordingly interfered in favour of the rightful heir, and restored him to the throne. In former times Bantam was a free port, open to the commerce of all nations. In 1683 the trade was monopolized by the Dutch, who erected Fort Spielwyk, to shut out all other merchants. This odious policy excited great discontents among the people, who were always the bitter enemies of the Dutch; but they were unable to shake off the yoke of their oppressors, who, about the year 1742, had succeeded in completely establishing their authority. The Bay of Bantam was formerly a commodious retreat for vessels; but it is now so choked up with daily accessions of new earth washed down from the mountains, as well as by coral shoals extending a considerable way to the eastward, that it is inaccessible to vessels of any considerable burden. Prior to the Dutch conquest, Bantam was a powerful state, the sovereign of which extended his conquests in the neighbouring islands of Borneo and Sumatra. It was abandoned by the Dutch in 1817, for the more elevated station of Ceram, seven miles inland, and it is now a miserable village. Long. 106. 3. E. Lat. 6. 4. S.

BANTRY, a small seaport of Ireland, on Bantry Bay, in Lat. 51. 39. N. Long. 9. 24. W. The trade of this port, formerly considerable, is now almost confined to the exportation of grain. The pilchard fishery was once very productive, but that fish has deserted the coast. The population, which in 1831 was 4276, had decreased in 1851 to 2935.

BANTRY BAY, an inlet of the sea, on the S.W. coast of Ireland, in the county of Cork, about twenty-five miles long by four to six broad, having from ten to thirty or forty fathoms of water, surrounded by high mountains, and indented by creeks and inlets. It affords a very fine harbour for shipping, and contains two small islands, Bear and Whiddy. In 1796 a French fleet anchored here with a view of invading Ireland, and landed eight men, who were immediately taken prisoners. The fleet soon after left the coast. Long. 9. 24. to 9. 45. E. Lat. 51. 30. to 51. 40. N.

BAOBAB (*Adansonia digitata*), the largest of trees, measuring sometimes thirty feet in diameter; but its height is not in proportion. It inhabits the western side of Africa, and is cultivated in Egypt and Abyssinia. The largest are at Senegal.

BAPAUME, a fortified town in France, capital of a canton in the department of Pas de Calais, 15 miles S.S.E. of Arras. It is neat and well built, has a parish church, hospital, communal college, and a fountain supplied with water by an artesian well. Its manufactures of lace, woollens, cottons, and fine thread, are considerable. Pop. 2973.

Baphomet ‖ Baptism.

BAPHOMET, the imaginary symbol or idol which the Templars were accused of worshipping in their secret rites. See TEMPLARS. The term is supposed to have been a corruption of the name *Mahomet*. On this subject, the learned Von Hammer has written a dissertation, in which he revives the old charge against the Templars. The word, according to his interpretation, signifies the baptism of *Metis* or of fire. This was replied to by M. Raynouard, in the *Journal des Savans*, March 1819.

BAPTISM, in matters of religion, the ceremony or sacrament by which a person is initiated into the Christian church. The word is drived from the Greek βαπτιζω, a frequentative form of βαπτω, *to dip* or *wash*. Baptism is known in ecclesiastical writers by divers other names and titles. Sometimes it is called *palingenesia*, or *regeneration*; sometimes *salus*, or *life and salvation*; sometimes σφραγις, *signaculum Domini*, and *signaculum fidei*, or *the seal of faith*; sometimes absolutely *mysterium*, and *sacramentum*; sometimes *the sacrament of faith*; sometimes *viaticum*, from its being administered to departing persons; sometimes *sacerdotium laici*, or the *lay priesthood*, because allowed, in cases of necessity, to be conferred by laymen; sometimes it is called the *great circumcision*, because it was imagined to succeed in the room of circumcision, and to be a seal of the Christian covenant, as circumcision was the seal of the covenant made with Abraham. In respect that baptism had Christ for its author, and not man, it was anciently known by the name of δωρον and χαρισμα Κυριου, *the gift of the Lord*; sometimes it was simply called δωρον, without any other addition, by way of eminence, because it was both a gratuitous and singular gift of Christ. In reference to the making men complete members of Christ's body, the church, it had the name of τελειωσις, and τελειη, the *consecration* and *consummation*, because it gave men the perfection of Christians, and a right to partake of το τελειον, which was *the Lord's Supper*. It had also the name of μυησις, and μυσταγωγια, the *initiation*, because it was the admission of men to all the sacred rites and mysteries of the Christian religion.

Baptism has been supposed by many learned authors to have had its origin in the Jewish church, in which, as they maintain, it was the practice long before Christ's time to baptize proselytes or converts to their faith, as part of the ceremony of admission; and this practice, according to some, obtains among them to this day, a person turning Jew being first circumcised, and, when healed, bathed or baptized in water, in presence of the rabbin, after which he is reputed a good Jew. Others, however, insist that the Jewish proselyte baptism is not by far so ancient; and that John the Baptist was the first administrator of baptism among the Jews. Of this opinion were Deylingius, J. G. Carpzovius, Boernerus, Wernsdorfius, Zeltnerus, Owen, Knatchbull, Jennings, Gill, and others.

Grotius is of opinion that the rite of baptism derives its origin from the time of the Deluge, immediately after which, he thinks, it was instituted in memory of the world having been purged by water. Some learned men think it was added to circumcision soon after the Samaritan schism, as a mark of distinction to the orthodox Jews. Spencer, who is fond of deriving the rites of the Jewish religion from the ceremonies of the Pagans, lays it down as a probable supposition, that the Jews received the baptism of proselytes from the neighbouring nations, who were wont to prepare candidates for the more sacred functions of their religion by a solemn ablution, that, by this affinity of sacred rites, they might draw the Gentiles to embrace their religion, and that the proselytes, in the gaining of whom they were extremely diligent, might the more easily comply with the transition from Gentilism to

Baptism. Judaism. In confirmation of this opinion, he observes, first, that there is no divine precept for the baptism of proselytes, God having enjoined only the rite of circumcision for the admission of strangers into the Jewish religion; and, secondly, he contends, that, among foreign nations, the Egyptians, Persians, Greeks, Romans, and others, it was customary for those who were to be initiated into their mysteries or sacred rites, to be first purified by dipping the whole body in water. The same learned writer adds, as a further confirmation of his opinion, that the cup of blessing, added to the paschal supper, seems likewise to have been derived from a pagan original; as the Greeks at their feasts had one cup called ποτηριον αγαθου δαιμονος, *the cup of the good demon or god*, which they drank at the conclusion of their entertainment when the table was removed. Since, then, a rite of Gentile origin was added to one of the Jewish sacraments, namely, the passover, there can be no absurdity, he thinks, in supposing that baptism, which was added to the other sacrament, namely circumcision, might be derived from the same source. In the last place, he observes, that Christ, in the institution of his sacraments, paid a peculiar regard to those rites which were borrowed from the Gentiles; for, rejecting circumcision and the paschal supper, he adopted into his religion baptism and the sacred cup; thus preparing the way for the conversion and reception of the Gentiles into his church.

The design of the Jewish baptism, if baptism was practised by them, is supposed to have been to import a regeneration, whereby the proselyte was rendered a new man, and from being a slave became free. The effect of it was, to cancel all former relations; so that those who were before akin to the person, after the ceremony ceased to be so. It is to this ceremony Christ is supposed to have alluded, in his expression to Nicodemus, that it was necessary that he should be born again, in order to become his disciple. The necessity of baptism to salvation is grounded on these two sayings of our Saviour, "He that believeth, and is baptized, shall be saved;" and "Except a man be born of water and of the Spirit, he cannot enter into the kingdom of God." The ancients did not generally think the mere want of baptism, where the procuring of it was impracticable, excluded men absolutely from the hopes of eternal salvation. Some few of them, indeed, are pretty severe upon infants dying without baptism; and others seem also, in general terms, to deny eternal life to adult persons dying unbaptized. But when they interpret themselves, and speak more distinctly, they make some allowances, and specially except several cases in which the want of baptism may be supplied by other means. Such is martyrdom, which commonly goes by the name of "second baptism in men's own blood" in the writings of the ancients, because of the power and efficacy it was thought to have in saving men by the invisible baptism of the Spirit, without the external element of water. Faith and repentance were also esteemed a supplement to the want of baptism, in such catechumens as died whilst they were piously preparing themselves for baptism. Constantly communicating with the church was also thought to supply the want of baptism to persons who had been admitted to communion on a presumption of their having been duly baptized, though the contrary afterwards appeared. For infants dying without baptism, the case was thought more dangerous; as here, no personal faith, repentance, or the like, could be pleaded, to supply the defect, and to wash away original sin. On this account, they who spoke most favourably of them, as Gregory Nazianzen, and Severus, bishop of Antioch, only assigned them a middle state, neither in heaven nor hell. But the Latins, as St Augustin, Fulgentius, Marius Mercator, and others, who never admitted the opinion of a middle state, concluded, that, as they could not be received into heaven, they must go to hell. Pelagius and his followers, who denied original sin, asserted that they might be admitted to eternal life and salvation, although not to the kingdom of heaven; between which a distinction was made. Where the fault lay not on the side of the child, nor his parents, but on that of the minister, or where any unavoidable accident rendered baptism absolutely impossible, Hincmar and others made an exception, holding that the child might in that case be saved without baptism. Baptism.

The receiving of baptism is not limited to any time, nor to any age of life. Some contend for its being administered like circumcision, precisely on the eighth day, as Gregory Nazianzen; while others would have it deferred till the child is three years of age, and able to hear the mystic words, and make answer thereto, though he do not understand them. In the canon law we find divers injunctions against deferring the baptism of infants beyond certain days, as the ninth, thirtieth, and thirty-seventh, some of them involving pecuniary forfeitures in case of disobedience.

Salmasius, and Suicerus after him, deliver it as authentic history, that for the first two ages no one received baptism who was not first instructed in the faith and doctrine of Christ, so as to be able to answer for himself that he believed; and this by reason of the words, "He that believeth and is baptized;" which in effect is to say, that no infant, for the first two ages, was ever admitted to Christian baptism. They own, however, that pædobaptism afterwards came in, upon the opinion that baptism was necessary to salvation. But Vossius, Dr Forbes, Dr Hammond, Mr Walker, and especially Mr Wall, who has exactly considered the testimony and authority of almost every ancient writer who has said any thing upon this subject, endeavour to evince that infants were baptized even in the apostolical age; and it is certain that Tertullian pleads strongly against giving baptism to infants; which at least shows that there was some such practice in his age, though he disapproved of it. But the ordinary subjects of this sacrament in the first ages were converts from Judaism and Gentilism, who, before they could be admitted to baptism, were obliged to spend some time in the state of catechumens, to qualify them for making their professions of faith and a Christian life, in their own persons; for, without such personal professions, there was ordinarily no admission of them to the privilege of baptism. Those baptized in their sick beds were called *clinici*, and held in some reproach, as not being reputed good Christians; and hence we meet with several censures of clinic baptism in councils and ecclesiastical writers. But this clinic baptism was not sufficient to qualify the person, in case of recovery, for ordination. Some had their baptism put off by way of punishment, when they fell into gross and scandalous crimes, which were only to be expiated by a long course of discipline and repentance. This sometimes included five, ten, twenty, or more years; in particular cases the whole of life to the very hour of death, when very flagrant crimes had been committed.

In the earliest ages of the church, there was no stated time or place for the reception of baptism. Afterwards, Easter, Whitsuntide, and Epiphany, became solemn seasons, out of which baptism was not administered, except in cases of necessity. The catechumens who were to receive it at these times were called *competentes;* and it is to these that St Cyril addresses his catecheses. In the apostolical age, and some time after, before churches and baptisteries were generally erected, they baptized in any place where they had convenience; for example, John baptized in Jordan, Philip baptized the eunuch in the

Baptism. wilderness, and Paul baptized the jailer in his own house. But in after-ages baptisteries were built adjoining to the churches; and then rules were made that baptism should ordinarily be administered nowhere except in these buildings. Justinian, in one of his *novellæ*, refers to ancient laws appointing that none of the sacred mysteries of the church should be celebrated in private houses. Men might have private oratories for prayer in their own houses; but they were not to administer baptism or the eucharist in them, unless by a particular license from the bishop of the place. Such baptisms are frequently condemned in the ancient councils, under the name παραβαπτισμαται, *baptisms in private conventicles.*

As to the attendant ceremonies and manner of baptism in the ancient church, the person to be baptized, if an adult, was first examined by the bishop or officiating priest, who put some questions to him; as, first, whether he abjured the devil and all his works, and, secondly, whether he gave a firm assent to all the articles of the Christian faith; to each of which he answered in the affirmative. If the person to be baptized was an infant, these interrogatories were answered by his *sponsores* or godfathers. Whether the use of sponsors was as old as the days of the apostles is uncertain; the probability is it was not, since Justin Martyr, speaking of the method and form of baptism, says not a word of them. After the questions and answers, followed exorcism, the manner and end of which was this: The minister laid his hands on the person's head, and breathed in his face, implying thereby the driving away or expelling of the devil, and preparing the convert for baptism, by which the good and holy spirit was to be conferred upon him. After exorcism followed baptism itself. And, first of all, the minister, by prayer, consecrated the water for that purpose. Tertullian says, "any waters may be applied to that use; but then God must be first invocated; on which the Holy Ghost presently comes down from heaven, and moves upon them, and sanctifies them." The waters having been consecrated, the person was baptized "in the name of the Father, and of the Son, and of the Holy Ghost;" by which "dedication of him to the blessed Trinity, the person," says Clemens Alexandrinus, "is delivered from that corrupt trinity, the devil, the world, and the flesh." In performing the ceremony of baptism, the usual custom, except in clinical cases, or where there was scarcity of water, was to immerse the whole body. Thus St Barnabas, describing a baptized person, says, "We go down into the water full of sin and filth, but we ascend bearing fruit in our hearts." And this practice of immersing the whole body was so general, that we find no exception made from respect either to the tenderness of infants or the bashfulness of the other sex, unless in case of sickness or disability. But, to prevent any indecency, men and women were baptized apart; to which end, either the baptisteries were divided into two apartments, one for the men, the other for the women, as Bingham has observed; or the men were baptized at one time and the women at another, as is shown by Vossius, from the *Ordo Romanus*, Gregory's *Sacramentarium*, and other authorities. Add to this, that there was anciently an order of deaconesses, one part of whose business was to assist at the baptism of women. These precautions, however, rather indicate a scrupulous attention to delicacy, than imply any indecency in the circumstance of immersion itself. From the circumstance of candidates being immersed, however, there is no reason to infer that immersion was made in a state of nudity. The present Baptists never baptize naked, though they always immerse. After immersion followed the unction; by which, according to St Cyril, was signified that they were now cut off from the wild olive, and were ingrafted into Christ, the true olive tree; or else to show that they were now to be champions for the gospel, and were anointed thereto, as the old athletæ were for their solemn games. With this anointing was joined the sign of the cross, made upon the forehead of the person baptized; which being done, he had a white garment given him, to denote his being washed from the defilements of sin, or in allusion to that of the apostle, "As many as are baptized in Christ have put on Christ." From this custom the feast of Pentecost, which was one of the annual seasons of baptism, came to be called *Whitesunday* or Whitsunday. The garment in question was afterwards laid up in the church, that it might be an evidence against such persons as violated or denied that faith which they had owned in baptism. When the baptism was performed, the person baptized, according to Justin Martyr, "was received into the number of the faithful, who then sent up their public prayers to God for all men, for themselves, and for those who had been baptized." Baptism.

The ordinary ministers, who had the right of administering this sacrament, that is, of applying the water to the body, and pronouncing the formula, were presbyters or bishops; but on extraordinary occasions laymen were admitted to perform the same.

The present form of administering baptism in the church of Rome is as follows:—When a child is to be baptized, the persons who bring it wait at the door of the church for the priest, who comes thither in his surplice and purple stole, attended by his clerks. He begins with questioning the godfathers, whether they promise, in the child's name, to live and die in the true Catholic and Apostolic faith, and what name they would give the child. Then follows an exhortation to the sponsors; after which the priest, calling the child by its name, asks, "What dost thou demand of the church?" The godfather answers, "Eternal life." The priest proceeds: "If you are desirous of obtaining eternal life, keep God's commandments, thou shalt love the Lord thy God," &c.; after which he breathes three times in the child's face, saying, "Come out of this child, thou evil spirit, and make room for the Holy Ghost." Then he makes the sign of the cross on the child's forehead and breast, saying, "Receive the sign of the cross on thy forehead and in thy heart;" upon which, taking off his cap, he repeats a short prayer, and laying his hand gently on the child's head, repeats a second prayer; then he blesses some salt, and, putting a little of it into the child's mouth, pronounces these words, "Receive the salt of wisdom." All this is performed at the church door. The priest, with the godfathers and godmothers, coming into the church, and advancing towards the font, repeat the apostles' creed and the Lord's prayer. Arrived at the font, the priest exorcises the evil spirit again; and taking a little of his own spittle, with the thumb of his right hand rubs it on the child's ears and nostrils, repeating, as he touches the right ear, the same word, *Ephatha, be thou opened*, which our Saviour made use of to the man born deaf and dumb. Lastly, they pull off its swaddling-clothes, or strip it below the shoulders, during which the priest prepares the oil. The sponsors then hold the child directly over the font, observing to turn it due east and west; whereupon the priest asks the child, "whether he renounces the devil and all his works;" and the godfather having answered in the affirmative, the priest anoints the child between the shoulders in the form of a cross; then taking some of the consecrated water, he pours part of it thrice on the child's head, at each perfusion calling on one of the persons of the Holy Trinity. The priest concludes the ceremony of baptism with an exhortation. It may be added, that the Romish church allows midwives, in cases of danger, to baptize a

Baptism. child before it comes entirely out of its mother's womb; but it is to be observed, that as some part of the body of the child must appear before it can be baptized, it is baptized on that which first appears: if it be the head, it is not necessary to rebaptize the child; but if only a foot or hand appears, baptism must be repeated. A still-born child thus baptized may be buried in consecrated ground.

The Greek church differs from the Romish as to the rite of baptism, chiefly in performing it by immersion, or plunging the infant all over in the water.

The forms of administering baptism among us being too well known to require a particular description, we shall only mention one or two of the more material differences between the form as it stood in the first liturgy of King Edward, and that in the English Common Prayer Book at present. First, the form of consecrating the water did not make a part of the office in King Edward's liturgy, as it does in the present, because the water in the font was changed and consecrated but once a month. The form itself likewise was something different from that now used, and was introduced with a short prayer, that Jesus Christ, upon whom (when he was baptized) the Holy Ghost came down in the likeness of a dove, would send down the same Holy Spirit, to sanctify the fountain of baptism; which prayer was afterwards left out at the second review. By King Edward's first book the minister was required to dip the child in the water thrice; first, the right side; secondly, the left; and, lastly, the face toward the foot. This triple immersion was a very ancient practice in the Christian church, and used in honour of the Holy Trinity; though some later writers say that it was done to represent the death, burial, and resurrection of Christ, together with his three days' continuance in the grave. But afterwards, when the Arians made an improper use of it, persuading the people that it denoted a distinct substantiality of the three persons in the Trinity, the orthodox left it off and used only one single immersion.

By the first common prayer of King Edward, after the child was baptized, the godfathers and godmothers were to lay their hands upon it, and the minister was to put on him the white vestment, commonly called the *chrysome*, and to say, "Take this white vesture as a token of the innocency which, by God's grace, in this holy sacrament of baptism, is given unto thee, and for a sign whereby thou art admonished, so long as thou livest, to give thyself to innocence of living, that after this transitory life thou mayest be partaker of the life everlasting." As soon as he had pronounced these words he was to anoint the infant on the head, saying, "Almighty God, the father of our Lord Jesus Christ, who hath regenerated thee by water and the Holy Ghost, and hath given unto thee remission of all thy sins, may he vouchsafe to anoint thee with the unction of his Holy Spirit, and bring thee to the inheritance of everlasting life."

The custom of sprinkling children instead of dipping them in the font, which at first was allowed in case of the weakness or sickness of the infant, has so far prevailed that immersion is now quite excluded. What principally tended to confirm the practice of affusion or sprinkling was, that several of our Protestant divines flying into Germany and Switzerland during the bloody reign of Queen Mary, and returning home when Queen Elizabeth came to the crown, brought back with them a great zeal for the Protestant churches beyond sea where they had been sheltered and received; and having observed that at Geneva and other places baptism was administered by sprinkling, they thought they could not do the church of England a greater piece of service than by introducing a practice dictated by so great an authority as Calvin. This, together with the coldness of our northern climate, was what contributed to banish entirely the practice of immersing infants in the font. Baptism.

The different notions which have been entertained concerning the effects of baptism, it would be endless to enumerate. The Remonstrants and Socinians reduce baptism to a mere sign of divine grace. The Romanists, on the contrary, exalt its power, holding, that thereby all sin is entirely taken away by it; that it absolutely confers justification, and consequently grace *ex opere operato*. Some also speak of an indelible character impressed on the soul by it, called *character dominicus*, and *character regius*; but others hold this a mere chimera, maintaining that the spiritual character conferred in regeneration may easily be effaced by mortal sins. Dodwell contends that it is by baptism that the soul is made immortal, and that those who die without it cannot rise again; but he limits this effect to episcopal baptism alone. From the effects ordinarily ascribed to baptism, even by ancient writers, it would seem that the ceremony is as much of heathen as Jewish origin, since Christians do not restrain the use of it, like the Jews, to the admission of new members into the church, but hold, with the heathens, that it contains a virtue for remitting and washing away sins. The Brahmins are still said to baptize with this latter view at certain seasons in the river Ganges, to the waters of which they ascribe a cleansing or sanctifying quality; and hence it is that people flock from all parts, even of Tartary, in expectation of being thus eased of their load of sins. But in this point many Christians seem to have gone beyond the folly of the heathens. It was only the smaller sins of infirmity which these latter held to be expiable by washing; for crimes of a blacker dye, they allowed, no water could efface, no purgation discharge them. The Christian doctrine of a total remission of sins by baptism could not fail, therefore, to scandalize many amongst the heathen, and furnished the apostate Julian with an occasion for ridiculing Christianity itself: "Whoever," says he, "is guilty of rapes, murders, sacrilege, or any abominable crime, let him be washed with water, and he will become pure and holy."

In the ancient church, baptism was frequently conferred on Jews by violence; but the church itself never seems to have allowed of force on this occasion. By a canon of the fourth council of Toledo, it is expressly forbidden to baptize any one against his or her will. That which looks most like force in this case is to be found in two orders of Justinian; one of which appoints the heathen, and the other the Samaritans, to be baptized, with their wives and children and servants, under pain of confiscation. By the ancient laws, baptism was not to be conferred on image-makers, stage-players, gladiators, *aurigæ* or public drivers, magicians, or even strolling beggars, until they quitted such professions. Slaves were not allowed the privilege of baptism without the testimony and consent of their masters; excepting the slaves of Jews, heathens, and heretics, who were not only admitted to baptism, but, in consequence of the rite, had their freedom conferred on them.

Baptism by Fire, spoken of by John the Baptist, has given rise to much conjecture. The generality of the fathers held that believers, before they enter paradise, must pass through a certain fire, which is to purify them from all pollutions remaining unexpiated. But some, with St Basil, understand it of the fire of hell; others, of that of tribulation and temptation; while a few, with St Chrysostom, will have it to denote an abundance of graces. Some suppose it to mean the descent of the Holy Ghost on the apostles, in the form of fiery tongues; others maintain, that the word *fire* here is an interpolation, and that we are only to read the text, "He that shall come after me will baptize you with the Holy Ghost."

Baptism. The ancient Selucians and Hermians, understanding the passage literally, maintained that material fire was necessary in the administration of baptism. But we do not find how or to what part of the body they applied it, or whether they were satisfied with obliging the person baptized to pass through the fire. Valentinus rebaptized all who had received water-baptism, and conferred on them the baptism of fire.[1] Heracleon, cited by Clemens Alexandrinus, says that some applied a red-hot iron to the ears of the person baptized, as if to impress some mark upon him.

Baptism of the Dead, a custom which anciently prevailed among some people in Africa, of giving baptism to the dead. The third council of Carthage speak of it as a thing which ignorant Christians were fond of. Gregory Nazianzen also takes notice of the same superstitious opinion prevailing among some who delayed to be baptized. In his address to this kind of men, he asks, whether they stayed to be baptized after death. Philastrius also notices it as the general error of the Montanists or Cataphrygians, that they baptized men after death. The practice seems to have been grounded on a vain opinion, that when men had neglected to receive baptism in their life-time, some compensation might be made for this default by receiving it after death.

Baptism of the dead was also a sort of vicarious baptism, formerly in use, when, in the case of a person dying without baptism, another was baptized in his stead. This, St Chrysostom tells us, was practised among the Marcionites with a great deal of ridiculous ceremony. When a catechumen happened to die, they hid a living man under the bed of the deceased: then coming to the dead man, they asked him whether he would receive baptism; and he making no reply, the other answered for him, and said he would be baptized in his stead; and so they baptized the living for the dead. Epiphanius assures us the like was also practised amongst the Corinthians. This practice they pretended to found on the Apostle's authority, alleging that text of St Paul for it, "If the dead rise not at all, what shall they do who are baptized for the dead?" a text which has given occasion to a great variety of different systems and explications. Vossius enumerates no less than nine different opinions among learned divines concerning the sense of the phrase, being "baptized for the dead."

Hypothetical Baptism was that formerly administered in certain doubtful cases, with the formula, "If thou art baptized, I do not rebaptize; if thou art not, I baptize thee in the name of the Father," &c. This sort of baptism, enjoined by some ancient constitutions of the English church, has now fallen into disuse.

Solemn Baptism was that conferred at stated seasons. Such, in the ancient church, were the paschal baptism, and that at Whitsuntide. This is sometimes also called general baptism.

Lay Baptism we find to have been permitted both by the common prayer-book of King Edward and by that of Queen Elizabeth, when an infant is in immediate danger of death, and a lawful minister cannot be had. This was founded upon the mistaken notion of the impossibility of salvation without the sacrament of baptism; but afterwards, when they came to have clearer notions of the sacraments, it was unanimously resolved, in a convocation held in the year 1575, that even private baptism, in a case of necessity, was only to be administered by a lawful minister.

Baptism is also applied abusively to certain ceremonies used in giving names to things inanimate. The ancients knew nothing of the custom of giving baptism to inanimate things, as bells, ships, and the like, by a superstitious consecration of them. The first notice we have of this is in the capitulars of Charles the Great, where it is mentioned with censure; but afterwards it crept by degrees into the Roman offices. Baronius carries its antiquity no higher than the year 968, when the great bell of the church of Lateran was christened by Pope John III. At last it grew to such superstitious height as to form a ground of complaint in the *Centum Gravamina* of the German nation, drawn up in the public diet of the empire held at Nuremberg in the year 1581; where, after describing the ceremony of baptizing a bell, with godfathers, who made responses as in baptism, and gave it a name, and clothed it with a new garment as Christians were used to be clothed withal, and all this to make it capable of driving away tempests and devils, they conclude against it as not only a superstitious practice, but contrary to the Christian religion, and a mere seduction of the simple people. Baptismal Vow ‖ Baptists.

BAPTISMAL Vow or Covenant, a profession of obedience to the laws of Christ, which persons in the ancient church made before baptism. It was an indispensable part of the obligation on catechumens before they were admitted to the ceremony of regeneration. The vow was made by turning to the east, for what mystical reason is not well agreed on.

Baptismal *Presents*, in use in Germany, were made by the sponsors to the infant, and consisted of money, plate, or even sometimes fiefs of lands, which by the laws of the country were to be kept for the child until he became of age; the parents having only the trust, not the right of disposing of them.

BAPTISTE, or Jean Baptiste Monnoyer, a painter of flowers and fruit, was born at Lisle in 1635, and educated at Antwerp. It was his first intention to become a painter of history; but finding that his genius more strongly inclined him to the painting of flowers, he applied his talents to those subjects, and in that style became one of the greatest masters. His pictures are not so exquisitely finished as those of Van Huysum, but his composition and colouring are in a bolder style. He was employed by William III. to decorate Kensington Palace. He died in 1699, leaving a son, Anthony, who followed his father's profession, and had great merit.

BAPTISTS, in *Ecclesiastical History*, a denomination of Christians, distinguished from other Christians by their particular opinions respecting the mode and the subjects of baptism.

Instead of administering the ordinance by sprinkling, they maintain that it ought to be administered only by immersion. Such, they insist, is the import of the word βαπτιζω; so that a command to baptize is a command to immerse. And thus it was understood by those who first administered it. John the Baptist and the apostles of Christ administered it in Jordan and other rivers and places where there was much water. Both the administrators and the subjects are described as going down into and coming up again out of the water; and the baptized are said to be buried in baptism, and to be raised again; which language could not, they say, be properly adopted on supposition of the ordinance being administered in any other manner than by immersion. Thus also, they affirm, it was in general administered in the primitive church; thus it is now administered in the Russian and Greek church; and thus it is at this day directed to be administered in the church of England to all who are thought

[1] Bis docuit tingi, transducto corpore flamma. (Tertull. *Carm. contr. Marc.* lib. i.)

Baptists. capable of submitting to it in this manner. With regard to the subjects of baptism, the Baptists say that this ordinance ought not to be administered to children or infants at all, nor to grown up persons in general; but to adults only of a certain character and description. Our Saviour's commission to his apostles, by which Christian baptism was instituted, is to go and teach all nations, baptizing them; that is, say they, not to baptize all they meet with, but first to instruct them, to teach all nations, or to preach the gospel to every creature, and whoever receives it, him to baptize in the name of the Father, and of the Son, and of the Holy Ghost. To such persons, and to such only, baptism appears to have been administered by the apostles and the immediate disciples of Christ. They are described as repenting of their sins, as believing in Christ, and as having gladly received the word. Peter acquaints those who were converted by his sermon, that without these qualifications he could not have admitted them to baptism; Philip holds the same language in his discourse with the Ethiopian eunuch; and Paul treats Lydia, the jailer, and others, in the same manner. Without these qualifications Christians in general think it wrong to admit persons to the Lord's supper; and for the same reasons, without these qualifications, or at least a profession of them, the Baptists think it wrong to admit any to baptism. Wherefore they withhold it, not only from the impenitently vicious and profane, and from infidels, who have no faith, but also from infants and children, who have no knowledge, and are incapable of every action civil and religious. They further insist that all positive institutions depend entirely upon the will and declaration of the founder; wherefore, that reasoning by analogy from abrogated Jewish rites is to be rejected, and the express commands of Christ respecting the mode and subjects of baptism ought to be our only rule.

The Baptists in England form one of the denominations of Protestant dissenters. They separate from the establishment for the same reasons as their brethren of the other denominations do; and an additional motive is derived from their particular tenets respecting baptism. The constitution of their churches, and their mode of worship, is congregational or independent; and in the exercise of it they are protected, in common with other dissenters, by the act of toleration. Before this act they were liable to pains and penalties as nonconformists, and often for their peculiar sentiments as Baptists. A proclamation was in fact issued out against them, and some of them were burnt in Smithfield in 1538. They bore a considerable share in the persecutions of the seventeenth and preceding centuries, and, as it should seem, in those of even an earlier date; for among the Lollards and the followers of Wickliffe there were several who disapproved of infant baptism, and there were many of this persuasion among the Protestants and reformers abroad. In Holland, Germany, and the North, they went by the names of Anabaptists and Mennonites; and, in Piedmont and the south, they were found among the Albigenses and Waldenses.

The *Baptists* subsist under two denominations; the Particular or Calvinistical, and the General or Arminian. The former is by far the most numerous. Some of both denominations allow of *mixed communion*, that is, with persons who have been sprinkled in their infancy, and therefore unbaptized in the view of the Baptists. Others, again, disallow it; and a few of them observe the seventh day of the week as the Sabbath, apprehending the law that enjoined it not to have been repealed by Christ or his apostles. But a difference of opinion respecting these and other matters is not peculiar to the Baptists, being common to all Christians, and to all bodies of men who think and judge for themselves.

BAPTISTERY, in ecclesiastical language, the name of a place in which the ceremony of baptism is performed. Baptistery ‖ Bar-le-Duc.

In the ancient church it was one of the exhedræ or buildings distinct from the church itself, and consisted of a porch or anti-room where the persons to be baptized made their confession of faith, and an inner apartment where the ceremony of baptism was performed. Thus it continued till the sixth century, when the baptisteries began to be taken into the church-porch, and afterwards into the church itself. The ancient baptisteries were commonly called φωτιστηρια, *photisteria*, or places of illumination, because they were the places of instruction preceding baptism; and in these the catechumens seem to have been trained up, and instructed in the first rudiments of the Christian faith.

Those baptisteries were anciently very capacious, because the stated times of baptism returning but seldom, there were usually great multitudes to be baptized at the same time; and also because the manner of baptizing by immersion or dipping under water made it necessary to have a large font. In Venantius Fortunatus it is called *aula baptismatis*, the large hall of baptism; which was indeed so large, that we sometimes read of councils meeting and sitting therein. This hall, or chapel, was always kept shut during Lent, and the door sealed up with the bishop's seal, not to be opened till Maunday-Thursday. The baptistery was always reputed a sacred place. In the Roman order baptisteries were built of a round figure, and distinguished with the image of St John the Baptist, while over the basin or font was a figure of a dove in gold or silver, to represent the Holy Ghost.

The name *baptistery* is sometimes also given to a kind of chapel in a large church, which served for the same office. It is an observation of some learned men, that anciently there was but one baptistery in a city, namely, at the bishop's church; and that afterwards they were set up in parish churches, with the special allowance, however, of the bishop.

BAR, in courts of justice, denotes an inclosure made with a partition of timber, where the counsel are placed to plead causes, and where prisoners are brought to answer to indictments, &c. It corresponds to what among the Romans was denominated *tribunal*. The French call it *barre d'audience*. In England, lawyers who are called to the bar, or licensed to plead, are termed *barristers*, an appellation equivalent to *licentiate* in other countries.

BAR, in *Heraldry*, an ordinary in form of the fess, but much less. See HERALDRY.

BAR, in *Music*, a stroke drawn perpendicularly across the lines of a piece of music, including between each two a certain quantity or measure of time, which is various as the time of the music is either triple or common. The use of bars is not to be traced higher than 1574; the time when the English translation of Adrian le Roy's book on the Tablature was published, and it was not until some time after that the use of bars became general. Barnard's cathedral music, printed in 1641, is without bars; but bars are to be found throughout in the *Ayres and Dialogues* of Henry Lawes, published in 1653; from which it may be conjectured that we owe this improvement to Lawes.

BAR, in *Hydrography*, denotes a bank of sand or other matter, whereby the mouth of a river is in a manner choked up. The term is also used for a strong beam wherewith the entrance of a harbour is secured; but this is more commonly called *boom*.

BAR-LE-DUC, or BAR-SUR-ORNAIN, a town of France, department of Meuse, and capital of an arrondissement of the same name. It occupies the declivity and base of a hill, on the river Ornain, a tributary of the Marne, 125 miles E. of Paris. Lat. 48. 46. 8. N. Long. 5. 9. 47. E. It has a college,

Bar-sur-Aube. ‖ Baralipton.

normal school, society of agriculture and arts, and public library. By the Ornain a considerable traffic is maintained in wood, wine, wool, &c. The manufactures of cotton stuffs, hats, hosiery, leather, and confections, are considerable. Pop. in 1851, 14,303. The arrondissement contains 8 cantons and 128 communes: pop. 86,358.

BAR-SUR-AUBE, an arrondissement of the department of the Aube, in France, comprehending 4 cantons and 88 communes. Area, 410 square miles. Pop. in 1851, 44,347. The chief place is the city of the same name, in a picturesque district, the wine of which is much esteemed. Pop. 4380. Long. 4. 44. E. Lat. 48. 13. N.

BAR-SUR-SEINE, an arrondissement of the department of the Aube, in France, comprehending 5 cantons and 85 communes. Area, 357 square miles. Pop. in 1851, 53,447. The chief place of the same name has a population of 2656 persons, employed in manufactures and the wine trade. In the middle ages this was a place of considerable importance. Long. 4. 24. E. Lat. 48. 5. N.

BARA, the name of a festival formerly celebrated with much magnificence at Messina, and representing the assumption of the Virgin. Though used as the general denomination of this festival, bara signifies more particularly a vast machine 50 feet high, at the top of which a young girl of fourteen, representing the Virgin, stood upon the hand of an image of the Saviour.

BARABA, a steppe or tract of land in Siberia, lying between the rivers Irtisch and Obi, in the province of Tobolsk. The soil is excellent for tillage, and part of it might also be laid out in meadows and pastures. It is interspersed with forests, and a great number of lakes which abound with a species of carp called by the people *karauschen;* and the country produces great numbers of elks, deer, foxes, ermines, and squirrels. Between the Irtisch and Obi are some rich copper mines, particularly on a mountain called Pictowa, from the *picta* or white firs that grow upon it. The ore, besides being rich in copper, yields a considerable portion of silver; and this, again, affords as much gold as makes a sufficient return for the trouble and expense of extracting it. The native population of this country are called Barabinzians.

BARACOA, a seaport town in the N.E. of Cuba. Long. 74. 30. W. Lat. 20. 22. N.

BARAHAT, a town of Northern Hindustan, situated among the Himalaya Mountains in the native state of Gurwhal. This town was almost destroyed by an earthquake in 1803; and from the houses having been built of large stones with slated roofs, the calamity was greatly aggravated. From its central position, it maintains a free communication with all parts of the hills, and those who make the pilgrimage to Gangautre generally halt here and lay in a stock of provisions for their journey. In the neighbourhood there is a curious trident, set up no doubt in honour of Siva, of whom, according to Hindu mythology, it is the proper equipment. The pedestal is of copper, the shaft of brass about 12 feet, and the forks about 6 feet in length. There is no tradition to show the origin of this curious relic of antiquity; and although it bears a legible inscription which most probably contains the information, no one has yet succeeded in deciphering the characters. The temple in which it was formerly inclosed was destroyed by the earthquake of 1803. The town is in Lat. 30. 43. Long. 78. 29. (E. T.)

BARALIPTON, in the *Old Logic*, a term denoting a syllogism of the first indirect mode of the first figure. Hence a syllogism in baralipton is when the first two propositions are universal affirmatives, the third a particular affirmative, and the middle term the subject in the first proposition, and the predicate in the second. For example,

BA. Every evil ought to be feared;
RA. Every violent passion is an evil;
LIP. Therefore something that ought to be feared is a violent passion.

Barangi ‖ Baratière.

BARANGI, officers among the Greeks of the lower empire. Cujacius calls them in Latin *protectores*, while others give them the name of *securigeri*. It was their business to keep the keys of the city gates where the emperor resided.

BARANYA, a province in the Austrian kingdom of Hungary, extending over 1960 square miles. It lies at the S.E. angle formed by the Danube and the Drave, and comprehends one city, 11 market-towns, and 341 villages, with about 260,000 inhabitants. The greater part of the land is fertile, but a portion of it is marshy and unhealthy. The chief products are corn, wine, flax, tobacco, aud potash. There are some valuable quarries of marble and millstones, and many mines of fossil coal. It is subdivided into six circles. The capital is Fünfkirchen.

BARANZANO, surnamed *Redemptus*, an eminent natural philosopher, born in Piedmont in 1590, was a Barnabite monk. His principal works are *Campus Philosophicus; Uranoscopia; Novæ Opiniones Physicæ.* He was greatly esteemed by Lord Bacon, with whom he corresponded. He died at Montargis in 1622.

BARATARIA, an island in the Gulf of Mexico, at the entrance of the bay of the same name.

BARATHRUM (*βάραθρον*, also called *ὄρυγμα*) in *Antiquity*, a deep dark pit at Athens, lined with sharp spikes, into which malefactors were cast. The *κεάδας* or *καιάδας* at Sparta was similar.

BARATIÈRE, or BARETTIER, JOHN PHILIP, an extraordinary instance of the early and rapid expansion of the mental faculties. This surprising genius was the son of Francis Baratière, minister of the French church at Schwabach, near Nuremberg, where he was born on the 10th January 1721. The French was his mother tongue; but in consequence of his father talking Latin to him, it became as familiar to him as his native idiom; and at four years of age, without knowing the rules of grammar, he talked French, Latin, and High Dutch, without mixing or confounding the respective languages. About the middle of his fifth year he acquired Greek in like manner; so that in fifteen months he perfectly understood all the Greek books in the Old and New Testament, which he readily translated into Latin. When he was five years and eight months old, he entered upon Hebrew, and in three years became so expert in the Hebrew text, that from a Bible without points he could give the sense of the original in Latin or French, or translate extempore the Latin or French versions into Hebrew, almost word for word; and he also acquired by heart all the Hebrew psalms. He composed at this time a dictionary of rare and difficult Hebrew words, with critical and philological observations; and, about his tenth year, amused himself for twelve months in reading the rabbinical writers. With these he intermixed the study of the Chaldaic, Syriac, and Arabic; and acquired a taste for divinity and ecclesiastical antiquity, by studying the Greek fathers, and the councils of the first four ages of the church. In the midst of these occupations a pair of globes having come into his possession, he was able in eight or ten days' time to resolve all the problems on them; and in about three months (January 1735) devised his project for the discovery of the longitude, which he communicated to the Royal Society of London and the Royal Academy of Sciences at Berlin. In June 1731 he was matriculated in the university of Altorf; and at the close of the year 1732 he was presented by his father at the meeting of the reformed churches of the circle of Franconia, which, astonished at his wonderful talents, admitted him to assist in the deliberations of the synod; and in order to preserve the memory of so singular an event, it was ordered to be registered in their acts. In 1734 the margrave of Brandenburg-Anspach granted this young scholar the use of whatever books he wanted from the Anspach library, together with a pension of fifty florins, which he enjoyed for three years. His father having received a call from the French church at Stettin in Pomerania,

Barbacan || Barbadoes.

young Baratière was, on the journey, admitted master of arts, with universal applause, at the university of Halle. While at Berlin he was honoured with several conversations with the king of Prussia, and received into the Royal Academy. Towards the close of his life he acquired a taste for the study of medals, inscriptions, and antiquities, which he relieved with metaphysical inquiries, and investigations in experimental philosophy. He wrote several essays and dissertations; made astronomical remarks and laborious calculations; prepared materials for a history of the heresies of the Anti-trinitarians, and of the Thirty Years' War in Germany; and, lastly, wrote a treatise, which appeared in 1740, on the succession of the bishops of Rome. The final work he engaged in, and for which he had accumulated large materials, was *Inquiries concerning Egyptian Antiquities*. But the substance of this blazing meteor was now almost exhausted. He had always been weak and sickly, and he died on the 5th October 1740, aged 19 years, 8 months, and 16 days. He published eleven different pieces, and left twenty-nine manuscripts on various subjects, the contents of which may be seen in his biography by Formey, Utrecht, 1741.

BARBACAN, or BARBICAN, a kind of watch-tower, or outer defence of a city or castle, used especially as a fence to the city or walls: also an aperture made in the wall of a fortress to fire through upon the enemy. It is also used to denote a fort at the entrance of a bridge or the outlet of a city, having a double wall with towers.

History.

BARBADOES, or BARBADOS, is one of the West India islands belonging to Britain, and the oldest of her settlements in that part of the world. The exact date of its discovery is unknown, but it was probably not later than the early part of the sixteenth century. The Portuguese are supposed to have been the first Europeans that visited this island, as it lay almost directly in their course to and from Brazil. They, however, had not regarded it as holding forth sufficient inducements for colonizing, as when first visited by the English in 1605 it was destitute of inhabitants, and covered with thick forests. The first English vessel that arrived there was the "Olive Blossom," the crew of which took possession of the island in the name of King James, by erecting a cross upon the spot where Jamestown was afterwards built, and cutting upon the bark of a tree that stood near, "James K. of E. and this island," James king of England and this island. The favourable accounts which Sir William Courteen, a London merchant, afterwards received of the island from one of his ships that had touched there, induced him to attempt a settlement. He accordingly fitted out two large vessels under the protection of Lord Ley, afterwards Earl of Marlborough, who had obtained a grant of this island from James I. One only of these ships arrived at its destination on 17th February 1625, and landed 40 English, and 7 or 8 negroes, who laid the foundation of a town, which, in honour of their sovereign, they called Jamestown.

The Earl of Carlisle, who had previously obtained from James I. a grant of all the Caribbean islands, disputed with Marlborough the possession of Barbadoes. This was at length settled by Carlisle agreeing to pay to Marlborough and his heirs an annuity of L.300, on which the island was made over to him by patent, dated 2d June 1627. Courteen was displeased at this arrangement, and accordingly applied to the Earl of Pembroke, who, during the temporary absence of Carlisle, obtained a grant of the island from Charles I. in 1628. On his return, however, Carlisle obtained the revocation of Pembroke's patent, and his own reinstatement in the possession. The insecure nature of his tenure now induced the earl to offer his lands in Barbadoes for sale, stipulating that each settler should pay him 40 lb. of cotton annually. On this condition a company of nine London merchants obtained a grant of 10,000 acres. They accordingly nominated as governor Charles Wolferstone, a native of Bermuda, who, with 64 settlers, to each of whom were allotted 100 acres, set out for Barbadoes, where they arrived in July 1628. The new colonists settled to the windward of the former settlers, and founded Bridgetown. The Pembroke men refused to submit to the authority of Lord Carlisle, in consequence of which disputes arose between them, which at length had to be referred to the two earls. These appealed to the king, who issued a second patent, dated 7th April 1629, confirming Carlisle as proprietor of the island. During the civil war that raged in England, a great number of families attached to the royal cause took refuge in Barbadoes. About the year 1647, Lord Carlisle, son of the original patentee, entered into an agreement with Francis Lord Willoughby, in terms of which the latter was to receive all the profits arising from the colony for twenty-one years, upon condition of paying one-half to the earl. This agreement received the sanction of the king, and Lord Willoughby was appointed governor of Barbadoes, and the other Caribbee islands. He accordingly arrived in Barbadoes in May 1650, where his first step was to convene the legislature, and to proclaim His Majesty's right to the dominion of the island. Soon after this the parliament sent out a strong force against the colony, under the command of Sir George Ayscue, and prohibited all foreign vessels from trading with the English colonies. Several attempts were made to get possession of the island, but without success, until a part of the inhabitants declared for the commonwealth, on which Lord Willoughby was obliged to treat for peace. Upon the restoration of the king, Lord Willoughby was again appointed governor, but, from the number of claimants on the island, the planters were apprehensive that the validity of their rights might sooner or later be disputed, and accordingly applied to His Majesty to have the grant to the Earl of Carlisle declared void. Carlisle, who died about this time, had bequeathed his West India possessions to the Earl of Kinnoul. Besides Lord Willoughby's claim for the moiety of the revenue during the remaining years of his lease, the creditors of the Earl of Carlisle now put in claims to a large amount, and the heirs of the Earl of Marlborough claimed the arrears of their annuity of L.300, which had never yet been paid. To satisfy these claims, Mr Kendall, in name of the planters, offered to consent to a tax of 4½ per cent. on all the exported produce of the island. An immediate settlement of the claims of the Earl of Kinnoul and the heirs of the Earl of Marlborough was proposed, and the division equally between Lord Willoughby and the earl's creditors of the net revenue during the remaining years of his lordship's lease, after which period, the remainder, after deducting as much as His Majesty should consider necessary for the support of the governor, was to be divided among the creditors. On the settlement of their claims, the whole revenue was to be at the disposal of the crown. The inhabitants of the island, however, denied the authority of Mr Kendall to offer the 4½ per cent., and at first refused to agree to it, but were at length induced to comply. This tax, for a long period, pressed heavily upon the planters of Barbadoes, and it was only repealed in the reign of Her present Majesty (1838). A fruitless attempt to get possession of this island was made in 1665 by the Dutch, under the command of Admiral De Ruyter. Bridgetown was nearly destroyed by fire in 1668, but was afterwards rebuilt in a more substantial manner. In 1669, the governor of Barbadoes was appointed governor-in-chief of all the Caribbee islands to the windward of Guadaloupe. An awful hurricane devastated the island in 1675. The following year a plot among the negroes to take possession of the island, was discovered in time to prevent much bloodshed. Two great fires in 1766 and 1767 nearly reduced Bridgetown to ashes. A tremendous hurricane in October 1780 destroyed almost every building on the island, and killed many of the inhabitants. The loss of human life has been estimated at 4326 souls, and of property at

Barbadoes.

Barbadoes. L.1,320,564. According to Poyer, however, 3000 persons perished, and the loss of property amounted to L.1,018,928. Between that and the last great hurricane of 1831, there were several others, the severest of which was that of October 1819, but these were less disastrous. The dreadful hurricane which desolated the island in August 1831 exceeded in violence any of the former. The number of persons who lost their lives is said to have amounted to upwards of 2000, and by some to upwards of 5000; and the loss of property to nearly L.1,602,800. There was an insurrection of the negroes in 1816, which involved a great sacrifice of life, and much destruction of property.

Physical description. Barbadoes is the most eastern of the Caribbee islands, lying 78 miles due E. of the island of St Vincent, between Lat. 13. 2. and 13. 19. N., and Long. 59. 26. and 59. 39. W. It presents almost the form of an irregular triangle; its greatest length in a direction N. by W. is nearly 21 miles, and its extreme breadth from E. to W. is 14½ miles. Its circumference, excluding the sinuosities of the bays, is 55 miles, and its area 106,470 acres, or about 166 square miles. In size, and in some measure in its outline, it bears a considerable resemblance to the Isle of Wight. It is almost encircled by coral reefs, which, in some parts, extend seaward for nearly three miles, and prove very dangerous to navigation.

Notwithstanding its small extent, Barbadoes presents considerable variety of surface, as valley, hill, table-land, &c. A deep valley running almost due E. from Bridgetown divides the island into two parts, of which the northern is by much the larger. Near the centre of the latter Mount Hillaby, the highest point of the island, rises to the height of 1147 feet. From the west coast the ground rises in distinct successive terraces, interrupted by ravines, to the central ridge; from which, and principally from Mount Hillaby, hills of a conical form radiate in a north-eastern direction toward the sea-shore: these are rugged and worn by the heavy rains and torrents which pour down their sides.

Geology. The north, west, and south parts of the island consist of rocks of coralline limestone, with beds of calcareous marl, containing numerous recent shells of various species: the east is composed of strata of siliceous sandstone, intermixed with ferruginous matter, calcareous sandstone passing into siliceous limestone, different kinds of clay, selenite, earthy marls, frequently containing minute fragments of pumice, strata of volcanic ashes, seams of bitumen, and springs of petroleum.

The rivers are all small, except during the rainy season, when they are much increased. There are several chalybeate springs, the principal of which are the Spa and the Cheltenham, so called from the fancied resemblance of their waters to the celebrated mineral springs of that name in Europe. These springs contain chiefly iron, carbonic acid, and fixed alkali, in different proportions. The "Boiling Spring" is a small spot where carburetted hydrogen escapes; and when the shallow excavation is filled with water, it has the appearance of being in a boiling state, though its temperature is not in the least changed. On the application of a flame, it burns with a whitish light.

Climate. Barbadoes is considered to be one of the healthiest islands of the West Indian archipelago. The climate, though warm, is very salubrious. In the forenoon, the mean temperature during the year is about 80°, and in the afternoon 82° Fahr.; the minimum being 75°, and the maximum 87°.

Population. Soon after its first settlement in 1625, the accounts of its great fertility attracted many immigrants from the mother country; and during the civil war in England, great numbers took refuge there. The accounts of its progress, however, are so contradictory, that they cannot be relied upon. In the report of the privy council in 1788, the population of the preceding year is stated to have been 16,127 whites, 2229 free coloured, and 64,405 negroes. According to the census of 1844, it contained 122,198 inhabitants, of whom 56,004 were males, and 66,194 females. This census, however, had been very carelessly taken, and the governor stated in his despatch, that the population was not less than 130,000. Even according to the census, there were 734·8 persons to each square mile, a denseness of population exceeding that of China. According to a census taken on the 25th of June 1851, the population (exclusive of the troops) was 135,939, of whom 62,272 were males, and 73,667 females; 15,824 white, 30,059 coloured, and 90,056 black. This gives 817·4 inhabitants to each square mile; yet notwithstanding this, it is stated in the government report, that so long as the seasons continue favourable, there is abundance for all its present population, and that "unless there should happen some material change for the worse in the returns of property here, the demand for labour will always rather exceed the quantity offering in the market than the contrary."

Barbadoes.

The island is divided into eleven parishes or districts, the area and population of which, according to the last-mentioned census, were as follows:—

	Area.	Population in 1851.		
		Male.	Female.	Total.
St Michael.....	9,580	16,071	21,395	37,466
Christ Church...	14,310	7,259	8,516	15,775
St Philip.....	15,040	6,550	7,348	13,898
St George.....	10,795	5,384	5,876	11,260
St John.....	8,600	4,235	4,660	8,895
St Thomas.....	8,500	4,679	5,131	9,810
St Peter.....	8,330	4,477	5,329	9,806
St Joseph.....	6,010	3,321	3,687	7,008
St Lucy.....	8,725	3,849	4,571	8,420
St James.....	7,800	3,168	3,716	6,884
St Andrew.....	8,780	3,279	3,438	6,717
	106,470	62,272	73,667	135,939

Bridgetown the capital, in the parish of St Michael, contained 20,026 inhabitants.

Religion. The Church of England is the established form of religion. The bishop has an income of L.4000; and in 1851 there were eleven rectors, who, besides a glebe and parsonage, and compensation in lieu of marriage and burial fees, had each a stipend of L.320; 18 curates at L.150; and two legislative chaplains. The dissenting bodies are not numerous, the Wesleyans and Moravians alone having missions here. The former have 8 churches, 4 preaching stations, with 3 missionaries, 14 local preachers, and about 2000 members; and the latter have 4 stations and 5 missionaries. There is a small Roman Catholic chapel, with one priest, principally for the soldiers of the garrison, the other adherents probably not exceeding 35 or 40. The Jews have a very handsome synagogue, erected in 1833; the congregation, however, numbers only about 70.

Education. Attached to almost all the churches and chapels there are Sunday-schools. Connected with the Established church are about 60 day-schools, almost all primary, in several of which the children are both clothed and fed. Harrison's free school was established in 1733 for the education of 24 poor children. The central school of Bridgetown was founded in 1819 for the maintenance and education of poor white children; and in 1846 it had 80 boarders and 71 day-scholars. The private schools are very numerous. The island is indebted to the munificence of General Codrington for the grammar school and college which bear his name. The course of studies pursued there embraces the classics, logic, mathematics, physics, surgery, theology, &c.

Public Institution. A small public library has been formed, which seems to be fully appreciated by the people; and the trustees accordingly have been encouraged to make exertions for its enlargement. There are also a literary and several agricultural societies. A general hospital was opened in 1844, and is attended gratuitously by six medical practitioners of

Barbara || Barbarossa

the first standing. There are also a leper and a lunatic asylum, an alms-house, and a number of charities for widows and orphans; and in Bridgetown a common jail, besides three houses of correction in the rural districts.

Commerce.

The chief staple articles produced in Barbadoes for export are sugar, arrow-root, aloes, and cotton. The following table gives the value of the imports and exports for the years 1849, 1850, and 1851:—

	Imports.	Exports.	Tonnage.
1849,	L.591,478	L.791,740	85,731
1850,	734,358	831,534	96,381
1851,	789,977	887,627	95,272

Carlisle Bay, the port or harbour of Barbadoes, forms an open roadstead, which is much exposed to the wind when blowing from the S. and S.W. It is spacious, and capable of containing upwards of 500 vessels of all sizes. It affords, however, no protection during gales; and at such times vessels at anchor generally prefer putting to sea, to running the risk of being driven ashore.

Government.

The local government consists of a governor-in-chief, assisted by a council and a house of assembly. The council consists of twelve members, appointed by mandamus of the sovereign, generally upon the recommendation of the governor, and holding office during the royal pleasure. The house of assembly is composed of 24 delegates, elected annually by the body of the people, two for each parish and two for the city of Bridgetown. The courts for the administration of civil justice are, the court of chancery, the court of common pleas, the court of exchequer, the court of ordinary, the court of admiralty, the court of error, and the court of escheat. The criminal courts are the court of grand sessions and the court of admiralty sessions. For dealing summarily, both in civil and criminal cases, police magistrates are appointed.

See Poyer's *History of Barbadoes;* Schomburgk's *History of Barbadoes*, 1848; *Colonial Reports*, &c.

BARBARA, in the *Old Logic*, the first mode of the first figure of syllogisms. A syllogism *in barbara* is one of which all the propositions are universal affirmatives, the middle term being the subject of the first proposition, and the predicate in the second.

BAR. All wicked men are miserable;
BA. All tyrants are wicked men;
RA. Therefore all tyrants are miserable.

BARBARIAN, a name given by the ancient Greeks and Romans to all who were not of their own country, or were not initiated in their language, manners, and customs. In this sense the word signified with them a foreigner; not, as among us, a rude or uncivilized person.

BARBARISM, in a general sense, a rudeness of language or behaviour.

BARBARISM, in *Grammar*, an offence against the purity of style or language, or a form of speaking or writing contrary to the true idiom of any particular language.

BARBAROSSA, ARUCH and HAYRADDIN, two famous corsairs in the sixteenth century, sons of a potter in the Isle of Lesbos. Having taken to piracy, they carried on their depredations with such success, that they soon became possessed of twelve galleys besides smaller vessels. Of this fleet Aruch, the elder brother, called *Barbarossa* from the redness of his beard, was admiral, and Hayraddin the second in command. They called themselves the "friends of the sea," and the "enemies of all who sailed upon it;" and their names became terrible from the straits of the Dardanelles to those of Gibraltar. They acquired territorial power in 1516, in consequence of an unwise application made to them by Eutemi, ruler of Algiers, for assistance against the Spaniards. Aruch, leaving his brother to command the fleet, carried 5000 men to Algiers, where he was hailed as a deliverer; but having secretly murdered the prince he had come to aid, he caused himself to be proclaimed king. To this usurpation he added the conquest of Tremecen, when his exploits and piracies induced the Emperor Charles V. to furnish the Marquis de Comares, governor of Oran, with troops to put him down; and in the contest which ensued he was defeated and killed near Tremecen, A.D. 1518. His brother, Hayraddin, known also by the name of Barbarossa, assumed the sceptre at Algiers with the same abilities, and with better fortune; for the Spaniards being too much employed in Europe to give him any disturbance, he regulated the interior police of his kingdom with great prudence, carried on his naval operations with vigour, and extended his conquests on the continent of Africa. He put his dominions under the protection of the Grand Signior, Suleiman the Magnificent, and obtained the command of the Turkish fleet. With so powerful a protector he acquired the kingdom of Tunis, in a manner similar to that by which his brother obtained Algiers. See ALGIERS.

Barbary || Barbauld.

BARBARY, the general designation of that part of Northern Africa which is bounded on the E. by Egypt, W. by the Atlantic, S. by the Sahara, and N. by the Mediterranean; comprising the states of Marocco, Algeria, Tunis, and Tripoli. See AFRICA, ALGIERS, MAROCCO, TRIPOLI, TUNIS, &c.

BARBASTRO, a city of Spain, in the province of Huesca, on the River Vero, near its junction with the Cinca. It is fortified, and has a cathedral and seven other churches, with several hospitals. Pop. 6200, chiefly employed in tanning and currying leather. Long. 0. 20. W. Lat. 41. 54. N

BARBATELLI, BERNARDINO, otherwise called *Pochetti*, a painter of fruit, animals, and flowers, was born at Florence in 1542. He was the disciple of Ridolfo Ghirlondaio at Florence. His touch was free, light, and delicate, and his colouring true. The historical subjects also which he designed from sacred or profane authors were much admired. He died in 1612.

BARBAULD, ANNA LETITIA, was born at Kibworth, in Leicestershire, on the 20th June 1743. She was the daughter of the Rev. John Aikin, LL.D., a minister of the Presbyterian denomination, who had a private seminary at Kibworth, and removed in 1758 to Warrington, in Lancashire, to superintend the public academy in that place. His daughter was remarkable for the abilities she displayed at a very early age; and, beside the usual female accomplishments, she soon acquired a knowledge of the Latin and Greek tongues. She was distinguished in the literary society of Warrington for the variety of her attainments and the elegance of her taste, which were rendered still more attractive by her personal beauty, vivacity, and amiable disposition. In 1774 she married the Rev. Rochemont Barbauld, who was descended of a French Protestant family, and had studied under her father. They opened a school at Palgrave, in Suffolk, which they carried on successfully during eleven years. Among the number of their pupils were Sir William Gell and Lord Denman. Mrs Barbauld's *Hymns in Prose*, which are poetry in everything but metre, were composed for the instruction of her pupils; as were also the *Early Lessons*, one of the standard works for children, published in 1775. Her *Devotional Pieces* appeared during the same year. Besides various other literary productions, she engaged with her brother, Dr Aikin, in the popular work entitled *Evenings at Home*, which appeared in 1793. After a sojourn of two years on the continent with her husband to recruit their health, Mr Barbauld accepted an invitation to become the pastor of a dissenting congregation at Hampstead, where they resided from 1787 till 1802. They then took up their residence at Stoke-Newington, in consequence of Mr Barbauld's having accepted a similar charge at Newington Green. Mrs Barbauld lost her husband in 1808; and her brother, Dr Aikin, died in 1822. Her own death followed on the 9th March 1825. She left no children. Her collected works, with a memoir of her life by her niece,

Barbe ‖ Barbezieux.

Miss Lucy Aikin, were published soon after her death, in 2 vols. 8vo.

BARBE, Barb, or Barde, is an old word, denoting the armour of the horses of the ancient knights and soldiers, who were accoutred at all points. It consisted of iron and leather, and defended the neck, breast, and shoulders of the horse.

BARBER, one whose occupation it is to shave or trim beards. In former times the barber's craft was dignified with the title of a profession, being conjoined with the art of surgery. In France the barber-surgeons were separated from the perruquiers, and incorporated as a distinct body in the reign of Louis XIV. In England the barbers and surgeons were not separated till the 18th of Geo. II. The functions of the barber-surgeon comprised the cure of wounds, simple surgical operations, and blood-letting, together with shaving, and the cutting and dressing of hair, technically termed *trimming*. The barber's shop in those days was a favourite resort of idle persons; and in addition to its attraction as a focus of news, a lute, viol, or some such musical instrument, was always kept for the entertainment of waiting customers. The barber's sign consisted of a striped pole, from which was suspended a basin, symbols the use of which is still preserved. The fillet round the pole indicated the ribbon for bandaging the arm in bleeding, and the basin the vessel to receive the blood. The setting of fractured limbs was confined to a distinct class of persons called *bone-setters*.

BARBERINI VASE. See Portland Vase.

BARBERINO, Francesco da, called by some authors Francesco Tafani, one of the best poets of his age, was born at Barberino, in Tuscany, in the year 1264. His mother was a native of Florence; and he settled in that city, where he followed the profession of the law, and became distinguished for the beauty of his poetry. The greater part of his works are lost; but that which is entitled *Documenti d'Amore*, a moral poem calculated to instruct those in their duty who have a regard for glory, virtue, and eternity, has had a better fate. It was published at Rome in quarto in 1640, by Frederic Ubaldini, who prefixed a life of the author; to which he added a glossary to explain the obsolete words it contains. Barberino died in 1348.

Barberino, a town of Tuscany, in Italy, situated at the foot of the Apennines. Lat. 43. 33. N. Long. 11. 18. E.

BARBERRY, *Oxyacanthus*, a spiny, shrubby plant, of the genus *Berberis*, which produces a berry, used in conserves, &c. The bark, especially that of the root, affords a fine yellow dye. It is remarkable for the irritability of its stamens.

BARBEYRAC, Jean, the son of Charles Barbeyrac a distinguished physician of Montpelier, was born at Beziers in Lower Languedoc, in 1674. He was successively professor of belles lettres at Berlin, of law and history at Lausanne, and of public law at Groningen. His death took place in 1729. He translated into French the two celebrated works of Pufendorf, his *Law of Nature and Nations*, and his *Duties of a Man and a Citizen*; to both of which he added excellent notes, and to the former an introductory preface. He translated also Grotius's treatise *De Jure Belli ac Pacis*, with large and excellent notes; several of Tillotson's *Sermons*; Cumberland's treatise on the *Law of Nature*; and various other works. He compiled a supplement, in five vols. folio, to the collection of treatises named *Grand Corps Diplomatique*; and was the author of an original work entitled *Traité de Jeu*, 2 vols. 8vo.

BARBEZIEUX, an arrondissement of the department of Charente, in France, extending over 400 square miles, and comprehending six cantons and eighty-seven communes, with 56,557 inhabitants. The town from which it takes its name is in a mountainous situation. Pop. in 1851, 3516. It is famous for its truffled capons. Long. 0. 11. W. Lat. 45. 29. N.

Barbieri ‖ Barbour.

BARBIERI, Giovanni Francesco (otherwise called Guercino, from his squinting), an eminent historical painter, was born at Cento, a village not far from Bologna, in 1590. At first he was a disciple of Benedetto Gennari; but he afterwards studied in the school of the Caracci, though he did not adopt the manner of that famous academy. He seemed to prefer the style of Caravaggio to that of Guido or Albano, imagining it impossible to imitate nature truly, without the assistance of strong lights and shadows; and on that principle the light was admitted into his atelier from above. His taste in design was natural, easy, and frequently grand. Towards the decline of his life he observed that the clearer and brighter style of Guido and Albano had attracted the admiration of all Europe; and he, accordingly, altered his manner, even against his own judgment. But he apologized for this conduct by declaring that formerly he had painted for fame and to please the judicious, but that now he painted to please the ignorant and enrich himself. He executed no fewer than 106 altar-pieces for churches, and 144 historical pictures, besides numerous works in fresco. His best performance is the history of Sta. Petronilla, which is considered one of the ornaments of St Peter's at Rome. He died in 1666.

Barbieri, *Paolo Antonio*, da Cento, painter of still life and animals, was the brother of Guercino, and born at Cento in 1596. He chose for his subjects fruits, flowers, insects, and animals, which he painted after nature with a lively tint of colour, great tenderness of pencil, and a strong character of truth and life. He died in 1640.

BARBITOS (Βάρβιτος), an ancient stringed instrument of music, said to have been invented by Anacreon. It resembled the *lyra*, but greatly exceeded it in the number of its strings. Yet Anacreon himself indiscriminately uses the two names for this instrument in his first ode.

Ἁ βάρβιτος δὲ χορδαῖς
Ἔρωτα μοῦνον ἠχεῖ.
——— λύρη δὲ
Ἔρωτας ἀντεφώνει.

BARBOUR, John, the contemporary and in some respects the rival of Chaucer, is the author of a poem which may justly be described as a national work: it relates the exploits of a very heroic monarch, whose memory is still cherished by his countrymen, and it displays so conspicuous a union of talent and patriotism, that, after the lapse of nearly five centuries, it has not ceased to attract an uncommon degree of attention. The orthography of this poet's name is very unsettled; it is to be found under the different forms of Barber, Barbere, Barbar, Barbare, and Barbour. It evidently belongs to that very numerous class of names originally derived from trades or occupations; but as *Barbour* appears to have been the ancient orthography of the word denoting this particular trade, there is sufficient propriety in adhering to the form now so generally adopted, and writing the name Barbour instead of Barber. Those authors who aver that he was born at Aberdeen, and educated in the abbey of Aberbrothick, seem to have substituted conjecture for evidence: no document which can enable us to ascertain the place of his birth or education has yet been discovered. His birth has been referred to the year 1316. When he describes the person of Randolph, says Lord Hailes, he seems to speak from personal observation; and as Randolph died in 1331 and Barbour in 1396, the poet, if we suppose him to have reached the age of 80, would have been 15 years old at the period of that illustrious warrior's death.[1] This however is but a vague calculation, resting on no solid basis; for he neither professes to describe the person of Randolph from actual observation,

[1] Hailes's *Annals of Scotland*, vol. ii. p. 3.

Barbour. nor is his description so minute and graphic as to justify the inference that he must have acquired his knowledge in this manner. It has been suggested by Dr Jamieson, that the strongest presumption of his having been born at so early a period, is to be found in the circumstance of his being a dignitary of the church in the year 1357. If we suppose him to have been born in 1316, he may have obtained this preferment about the age of forty; and the same learned writer remarks that it must have required very powerful interest to obtain it at a much earlier period. We are not however sufficiently acquainted with the details of his personal history, to be enabled to estimate the probability of his rapid promotion; but, according to the canon law, he could be regularly appointed an archdeacon at the age of twenty-five.[1] We must therefore be content to leave conjectural dates as we found them, without attempting to decide whether he was born in 1316, 1326, or 1330; but more authentic notices of this venerable archdeacon have fortunately been preserved. On the 13th of August 1357, Edward III., on the application of the Scottish king, granted Barbour a safeconduct to visit the university of Oxford, accompanied by three students.[2] This instrument expressly mentions that they are to repair thither for the purpose of study, and of performing scholastic exercises; and it has been stated by a distinguished ornament of the university that Barbour studied there during the years 1357 and 1365.[3] But as the safeconduct describes him as archdeacon of Aberdeen, we cannot so easily admit that he comes under the common denomination of an academical student, if by this term we understand a person subjected to college discipline, and following a prescribed course of study; nor is it unreasonable to conclude that the scholastic exercises were solely to be performed by the three scholars who accompanied him. That he completed his studies in this celebrated university, is however sufficiently probable, though it must apparently have been at an earlier period of life. We may venture to infer, that on the present occasion he repaired to Oxford, as many individuals still repair to it, for the purpose of conferring with learned clerks, and of consulting books which he had no opportunity of consulting at home; and such a document may therefore be regarded as an honourable testimony of his love of learning. Nor is it the only document of this kind. There is another safeconduct, dated on the 6th of November 1364, and authorizing the archdeacon of Aberdeen to visit England with four horsemen, in order to study at Oxford or elsewhere, as he may judge expedient;[4] and a third, dated on the 30th of November 1368, authorizes him to travel through England with two servants and two horses, on his way towards France for the same purpose of study.[5] On the 13th of September 1357, the bishop of his diocese had nominated him one of the commissioners who were to meet at Edinburgh, to deliberate concerning the ransom of the captive king;[6] but as he must then have received his passport for Oxford, it is conjectured that this nomination was only intended as a compliment, and that the actual duty was to devolve on a coadjutor, who is named in the same instrument. On the 16th of October 1365, Edward had granted him permission to travel through England, with six companions on horseback, towards St Denis and other sacred places;[7] an expression which seems to indicate that the object of his expedition was of a religious nature. After an interval of several years, his name occurs in another authentic record; namely, in the list of the auditors of exchequer, appointed on the 18th of February 1373, or, according to our present computation, 1374. Here he is described as archdeacon of Aberdeen, and "clericus probacionis domus domini nostri Regis;" and in the same commission we find the name of Sir Hugh Eglintoun.[8]

Barbour.

About this period, he was engaged in the composition of the work which has transmitted his name to posterity; for it appears from his own statement that in the year 1375 his work was more than half-finished.[9] Dr Henry has stated, but apparently without any competent authority, that it was undertaken at the request of David II., the son and successor of the heroic monarch whose actions the author commemorates; and that a considerable pension was granted to him as an encouragement to prosecute this design.[10] It is to be recollected that David died in 1371, several years before Barbour had written one half of his poem. The history of his pension was involved in much obscurity, which has at length been removed by the researches of Dr Jamieson. Hume of Godscroft had affirmed that his merit as the author of this poem was rewarded by a pension from the exchequer during his life, that he transferred this pension to the hospital of Aberdeen, and that it still continued to be paid in his own lifetime.[11] The terms of this statement are evidently at variance with each other; but the fact of his having received a pension, or rather two different pensions, from the crown, rests on unquestionable authority; and this fact cannot but be regarded as creditable to the government of his country, nor must the extent of such liberality be estimated by so fallacious a standard as the present value of money. At a much later period, Hector Boyce enjoyed a revenue of forty marks, as principal of King's College, Aberdeen. Barbour's pensions consisted of ten pounds payable from the customs of Aberdeen, and twenty shillings payable from the rent of the lands and fisheries which that city held of the crown.[12] The first was merely an annuity for his life, but the other was granted to him and his assignees, with an express permission to dispose of it in mortmain; and it appears from the records to have been granted by Robert II. as a reward for the composition of his historical poem.[13] This sum he did not bequeath to the hospital, but to the dean and chapter of Aberdeen, under the condition that they

Barbour. should say a yearly mass for the repose of his soul.[1] His larger pension seems likewise to have been conferred by the same king; and although this circumstance has not been traced in any record, it was probably conferred for the same reason.

Although the *Bruce* is the only work of Barbour that is known to be extant, it is not the only work of which he was the author. He appears to have written another book, doubtless in rhyme, comprising a genealogical history of the kings of Scotland, and deducing their origin from the Trojan colony of Brutus.[2] We may venture to conclude that his principal materials were drawn from very dubious sources; but although the historical value of this production may not have been very conspicuous, it would undoubtedly have been regarded as a curious relique of the literature of the middle ages. The existence of such a work is fully established by various passages in Winton's chronicle.

> This Nynus had a sone alsua,
> Sere Dardane lord of Frygia.
> Fra quham Barbere sutely
> Has made a propyr Genealogy,
> Tyl Robert oure secownd kyng,
> That Scotland had in governyng.[3]
>
> Of Brutus lyneage quha wyll her,
> He luk the tretis of Barbere,
> Mad in-tyl a Genealogy
> Rycht wele, and mare perfytly
> Than I can on ony wys
> Wytht all my wyt to yowe dewys.[4]

It is apparently the same book which the prior of Lochleven repeatedly quotes under the title of the Brute; and we agree with Dr Jamieson in thinking it highly probable that this book is quoted by Barbour himself in the subsequent passage.

> Als Arthur, that throw chevalry
> Maid Bretane maistres and lady
> Off twelf kinrykis that he wan;
> And alsua, as a noble man,
> He wan throw bataill Fraunce all fre,
> And Lucius Yber wencusyt he,
> That then of Rome was emperor
> Bot yeit, for all his gret valour,
> Mordreyt his systir son him slew
> And gud men als ma than inew,
> Throw tresoune and throw wikkitnes;
> The Broite beris thairoff wytnes.[5]

The archdeacon, as has already been hinted, died in 1396;[6] and as he had enjoyed his preferment for at least thirty-nine years, he must evidently have reached an advanced period of life. His character, if we may be allowed to form a conjecture from the general strain of his work, was of an amiable kind; and his name has long been respected by his countrymen. The earliest edition of the *Bruce* which has hitherto been traced was published at Edinburgh in 1616; but, as Patrick Gordon, whose poem was licensed in 1613, describes it as "the old printed book,"[7] there is reason to believe that the first impression is of a much earlier date. Several other editions appeared in the course of the seventeenth century; "and there are many later editions of no value, published by different booksellers, to answer the demand of the common people for this book; which, to the credit of their good sense, is very great."[8] A more elaborate edition was at length published by Mr Pinkerton, from a manuscript in the Advocates Library; but as the transcript was neither executed by himself, nor under his immediate inspection, many gross inaccuracies were suffered to escape.[9] After an interval of thirty years, another edition, the best that has yet appeared, was published by Dr Jamieson from a more careful collation of the same manuscript.[10] This appears from the colophon to have been transcribed in 1489, by John Ramsay, who is supposed to be the same person that was afterwards prior of the Carthusian monastery at Perth. The transcript was executed at the request of Simon Lochmalony, vicar of Moonsie; and thus every individual more immediately concerned, the poet, the copyist, and his employer, belonged to the church.

When we endeavour to appreciate the literary merit of Barbour, we must at the same time endeavour to transport ourselves to the remote and unrefined age in which he lived; we must recollect the general barbarism of many preceding centuries, the difficulty of acquiring liberal knowledge, the rude and grotesque taste of almost all his contemporaries. When all these circumstances are duly considered, his poem will be found entitled to an ample share of our approbation. Fortunate in the choice of a subject, he has unfolded a series of remarkable events, and has diffused over a very long narrative that lively interest which an ordinary writer is incapable of exciting. Here we are not to expect the blandishments of modern poetry: the author stands conspicuous amid the ruins of time, and, like an undecayed Gothic tower, presents an aspect of majestic simplicity. The lively strain of his narrative, the air of sincerity which he always exhibits, his earnest participation in the success or sufferings of his favourite characters, as well as the splendid attributes of the characters themselves, cannot fail of arresting the attention of every reader familiarly acquainted with the language in which he writes. The age of the great King Robert was the age of Scottish chivalry, and the monarch himself presented the most perfect model of a valiant knight. Whatever inconsistencies may have appeared in his early conduct, the best portion of his life was undoubtedly spent in the exercise of heroic valour or of political wisdom. Such a hero and such a crisis were a most fortunate selection; and although the intrinsic merit of the poet is very conspicuous, yet the attraction of the poem is partly to be ascribed to his judicious choice of a subject.

Barbour was evidently skilled in such branches of knowledge as were then cultivated, and his learning was so well regulated as to conduce to the real improvement of his mind: the liberality of his views, and the humanity of his

Barbour. sentiments, appear occasionally to have been unconfined by the narrow boundaries of his own age. He has drawn various illustrations from ancient history and from the stories of romance, but has rarely displayed his erudition by decking his verses with the names of ancient authors: the distichs of Cato,[1] and the spurious productions of Dares Phrygius and Dictys Cretensis are the only profane books to which he formally refers. He has borrowed more than one illustration from Statius, who was the favourite classic of those times, and who likewise appears to have been the favourite of Barbour: the more chaste and elegant style of Virgil and Horace was not so well adapted to the prevalent taste, as the strained thoughts and gorgeous diction of Statius and Claudian. The manner in which he has incidentally discussed the subject of astrology and necromancy, may be specified as not a little creditable to his good sense. It is well known that these branches of divination were assiduously cultivated during the ages of intellectual darkness. The absurdity of astrology and necromancy he has not openly attempted to expose; for as the opinions of the many, however unfounded in reason, must not be too rashly stigmatized, this might have been too bold and decided a step. Of the possibility of predicting events he speaks with the caution of a philosopher*; but the following passage may be considered as a sufficient indication of his deliberate sentiments:

> And sen thai ar in sic wenyng,
> For owtyne certante off witting,
> Me think quha sayis he knawis thingis
> To cum, he makys gret gabingis.[2]

To form such an estimate, required a mind capable of resisting a strong torrent of prejudice; nor is it superfluous to remark, that in an age of much higher refinement, Dryden suffered himself to be deluded by the prognostications of judicial astrology.[3] It was not however to be expected that Barbour should on every occasion evince a decided superiority to the general spirit of the age to which he belonged. His terrible imprecation on the person who betrayed Sir Christopher Seton, "In hell condampnyt mot he be!" ought not to have been uttered by a Christian priest. His detestation of the treacherous and cruel King Edward induced him to lend a credulous ear to the report of his consulting an infernal spirit. The misfortunes which attended Bruce at almost every step of his early progress, he attributes to his sacrilegious act of slaying Comyn at the high altar. He supposes that the women and children who assisted in supplying the brave defenders of Berwick with arrows and stones, were protected from Barbour. injury by a miraculous interposition. Such instances of superstition or uncharitable zeal are not to be viewed as marking the individual: gross superstition, with its usual concomitants, was the general spirit of the time; and the deviations from the ordinary track are to be traced in examples of liberal feeling or enlightened judgment.

His encomium on political freedom is distinguished by a manly and dignified strain of sentiment:

> A! fredome is a noble thing!
> Fredome mayss a man to haiff liking
> Fredome all solace to man giffis:
> He levys at ess that frely levys.
> A noble hart may haiff nane ess,
> Na ellys nocht that may him pless,
> Gyff fredome failyhe; for fre liking
> Is yharnyt our all othir thing.
> Na he that ay hass levyt fre,
> May nocht knaw weill the propyrte,
> The angyr, na the wrechyt dome
> That is cowplyt to foule thyrldome
> Bot gyff he had assayit it,
> Than all perquer he suld it wyt,
> And suld think fredome mar to pryss
> Than all the gold in warld that is.[4]

From the satisfaction with which the poet seems to contemplate any example of the gentler virtues, we may venture to draw a favourable inference respecting the native benevolence of his disposition. The subsequent passage cannot be passed without particular notice: the annals of heroes furnish but few instances of so pleasing a nature, whether it be that heroes seldom stoop to actions of mere benevolence,[5] or that their historians do not think it of much importance to transmit such actions to posterity.

> The king has hard a woman cry;
> He askyt quhat that wes in hy.
> "It is the layndar, Schyr," said ane,
> "That her child-ill rycht now has tane,
> "And mon leve now behind ws her;
> "Tharfor scho makys yone iwill cher."
> The king said, "Certis it war pite
> "That scho in that poynt left suld be;
> "For certis I trow thar is na man
> "That be ne will rew a woman than."
> Hiss ost all thar arestyt he,
> And gert a tent sone stentit be,
> And gert hyr gang in hastily,
> And othyr wemen to be hyr by,
> Quhill scho wes deliuer, he bad,
> And syne furth on his wayis raid:
> And how scho furth suld caryit be,
> Or euir he furth fur, ordanyt he.

---

[1] And Catone sayis ws in his wryt,
That to fenyhe foly quhile is wyt. (Barbour's *Bruce*, p. 13.)
This passage evidently refers to the collection of distichs which bears the name of Dionysius Cato, whom Chaucer likewise calls Caton or Cathon; a circumstance which, as Mr Warton remarks, shews that he was more familiarly known from the French translation than from the Latin original.

Insipiens esto quum tempus postulat aut res:
Stultitiam simulare loco, prudentia summa est. (Catonis *Disticha*, lib. ii. 18.)

This work of Cato was held in the highest estimation during the middle ages, and it has been translated into Greek, Anglo-Saxon, German, French, and English. It comprehends a series of moral lessons, which are often conveyed with a considerable degree of terseness and compression. The author possesses so much purity of diction, that Joseph Scaliger supposes he cannot have flourished subsequently to the reign of Commodus or Severus; and Hen. Cannegieter, who was alike conversant with philology and the civil law, has employed several arguments, drawn from the history of the Roman jurisprudence, to prove that this poet must at least have preceded the reign of Constantine. (*Rescripta Boxhornii de Catone*, cap. xviii.) Cato, for example, speaks of divorcing a wife, if she should become troublesome, "si cœperit esse molesta." (Lib. iii. 13.) But after the law of divorce had been modified by that emperor, it was not competent for a husband to dismiss his wife, merely because he did not find her agreeable. (*Codex Theodosianus*, lib. iii. tit. xvi.) The most complete edition of Dionysii Catonis *Disticha de Moribus ad Filium*, is the second published by Otto Arntzenius. Amst. 1754, 8vo. It contains the notes of many learned commentators, the Greek versions of Planudes and Scaliger, with the dissertation of Boxhornius, and the very copious reply of Cannegieter.

Barbour.

This wes a full gret curtasy,
That swilk a king, and sa mighty,
Gert his men duell on this maner
Bot for a pouir lauender.[1]

Barbour seems to have been acquainted with those nicer springs of human action which elude vulgar observation; he catches the shades of character with a delicate eye, and sometimes presents us with instances of nice discrimination. His work is not a mere narrative of events; it contains specimens of that minute and distinct delineation which marks the hand of a skilful artist. An illustration of this remark may perhaps be found in the following incident. When Bruce has with his single arm defended a narrow pass against a party of two hundred Gallovidians, his soldiers are represented as flocking around him with the same eager curiosity as if they had never had another opportunity of seeing him.

Syk wordis spak thai of the king,
And for his hey wndertaking
Farlyit, and yarnyt hym to se,
That with hym ay wes wont to be.[2]

In the opinion of an exquisite critic, Barbour has adorned the English language by a strain of versification, expression, and poetical imagery, far superior to the age.[3] And Dr Nott remarks that he "had given his countrymen a fine example of the simple energetic style, which resembled Chaucer's best manner, and wanted little to make it the genuine language of poetry."[4] The best method of estimating the merit of his versification, will be to compare it with that of some English poet who flourished about the same period; and, if placed in competition with the versification of Chaucer, Gower, or Lydgate, the most celebrated English poets of that era, it must certainly be admitted to appear with sufficient advantage. Although a general conclusion cannot safely be drawn from a particular instance, it may yet be worth while to compare the following quotations from Chaucer and Barbour:

The byrdes that han lefft her songe,
Whyle they han suffred colde full stronge
In wethers grylle, and derke to syght,
Ben in May, for the sunne bryght,
So glad that they shewe in syngyng
That in her herte is suche lyking,
That they mote syngen and ben lyght:
Than doth the nyghtyngale her myght
To maken noyse and syngen blythe;
Than is blysfull many a sythe
The chelaundre and the popyngay;
Than yonge folke entenden aye
For to ben gay and amarous,
The tyme is than so sauorious.[5]

This wes in ver, quhen wynter tid,
With his blastis hidwyss to bid,
Was our drywyn, and byrdis smale,
As turturis and the nychtyngale,
Begouth rycht sariely to synge,
And for to mak in thair singyng
Swete notis, and sownys ser,
And melodys plesand to her;
And the treis begouth to ma
Burgeans, and brycht blomys alsua,
To wyn the helyng off their hewid,
That wykkyt wyntir had thaim rewid.[6]

Here the versification of Barbour is certainly not inferior to that of Chaucer; but we have no intention to aver that the general merit of the two poets is equal. Chaucer has attempted a great variety of subjects, and, for the most part, with eminent success. His measures are also varied; and, if we compare his versification with that of preceding poets, or indeed with that of his immediate successors, it will be found entitled to high commendation. He reformed the taste and improved the language of his native country. The merit of Barbour, though more circumscribed, is yet so eminent as to entitle him to a very honourable place in the history of British poetry.

Barbour ‖ Barbuda.

The style of this poet is distinguished by its terseness, and he often exhibits a happy brevity of expression. His work contains a greater proportion of French idioms than we discover in the writings of the preceding Scottish poets, though their positive number is far from being considerable. Fiction is not inseparably connected with verse. The historical merit of Barbour's poem has been admitted by very competent judges; and, among others, Lord Hailes has repeatedly acknowledged the general fidelity of his narrative. King Robert died in 1329; and, as Barbour was employed in writing his poem within forty-six years from that period, he must have enjoyed many opportunities of collecting information. He might himself have conversed with warriors who fought at Bannockburn; and on one occasion he quotes the authority of a valiant knight, Sir Allan Cathcart, who was personally engaged in a particular exploit which he is about to relate.

A knycht, that then wes in his rowt,
Worthi and wycht, stalwart and stout,
Curtaiss and fayr, and off gud fame,
Schyr Alane off Catkert by name,
Tauld me this taile, as I sall tell.[7]

Of the general merit of Barbour's work, so favourable an estimate has been formed by Mr Pinkerton, that it may not be improper here to produce his testimony. "Perhaps the editor may be accused of nationality, when he says, that, taking the total merits of this work together, he prefers it to the early exertions of even the Italian muse, to the melancholy sublimity of Dante, and the amorous quaintness of Petrarca, as much as M. Le Grand does a *fabliau* to a Provençal ditty. Here indeed the reader will find few of the graces of fine poetry, little of the Attic dress of the muse; but here are life, and spirit, and ease, and plain sense, and pictures of real manners, and perpetual incident, and entertainment. The language is remarkably good for the time, and far superior in neatness and elegance even to that of Gawin Douglas, who wrote more than a century after. But when we consider that our author is not only the first poet, but the earliest historian of Scotland, who has entered into any detail, and from whom any view of the real state and manners of the country can be had; and that the hero whose life he paints so minutely, was a monarch equal to the greatest of modern times; let the historical and poetical merits of his work be weighed together, and then opposed to those of any other early poet of the present nations in Europe."[8] (D. I.)

BARBUDA, one of the Caribbee islands, is 15 miles in length by about 8 in breadth, presenting a very flat surface, covered to a great extent with forests of small trees, in which excellent deer abound. Many varieties of very fine shell and other fish are found on the coast, which is

Barca ‖ Barcelona.

also frequented by large flocks of water-fowl. The part of the island cultivated is fertile, but there is no sugar raised, nor are there any plantations of importance. The climate is very salubrious. Pop. about 1000. Long. 61. 46. W. Lat. 17. 36. N.

BARCA (the ancient *Cyrenaica*), a maritime district of Northern Africa, forming the eastern portion of Tripoli, and extending from the Gulf of Sert (the ancient Syrtes) to Egypt, between Lat. 30° and 33° N and Long. 20° and 25° E. Its name is derived from Barce or Barca, an ancient city of Cyrenaica, and which probably was originally a Libyan settlement, but afterwards colonized by Greeks from Cyrene, about B.C. 560. This territory is traversed from east to west by a mountain chain varying in height from 400 or 500 to upwards of 1800 feet. A great part of Barca, particularly towards the coast, is very fertile, abounding with excellent pasturage, and producing large supplies of corn. The chief town is Bengazi. See CYRENAICA.

BARCAROLLE (from the Italian *barcarola*, a bargeman), a popular song sung by the Venetian gondoliers.

BARCELONA, one of the four provinces into which the ancient Spanish principality of Catalonia was divided in 1833. It is bounded N.E. by Gerona, N.W. by Lerida, S.W. by Tarragona, and S.E. by the Mediterranean. Area, about 220 square leagues. Pop. (1849) 533,695. See CATALONIA.

BARCELONA, capital of the above province, and formerly the capital of Catalonia, is a strongly fortified city and seaport on the shore of the Mediterranean, between the mouths of the rivers Besos and Llobregat. Lat. 41. 22. N. Long. 2. 9. E. It stands in a plain of great fertility, which is covered with villas and gardens. The Montjuich hills lie to the west, and on the other side the view is bounded by the sea. On the north-east the city is defended by the citadel, fortified on Vauban's plan; and on the south-east by the fortress of Montjuich, which occupies a commanding position. The ramparts embrace about three-fourths of the town, forming a terrace from which there is a magnificent view of the city and its environs. A fine promenade called *La Rambla* divides the city into two parts, the high and the low town. The buildings, chiefly of brick, are irregular, and usually from four to five stories in height, with numerous windows and balconies; and the fronts are occasionally decorated with fresco-painting. The streets are generally narrow, but some of the *plazas* or squares are handsome, especially that of the Palacio, which contains the governor's palace, the exchange, and the custom-house. Among the more remarkable of the other public edifices, may be mentioned the cathedral, an ancient and majestic building in the later Gothic style; the churches of Sta Maria del Mar, S^{tos} Justo y Pastor, and San Miguel; the Casa de la Diputacion, or court of the chief justice, which contains the archives of Aragon, a most precious collection of historical documents; the Casa Consistorial; the Palacio Real, or ancient palace of the kings of Aragon; the Palacio de la Reina; the palace of the marquises of Aitona; the theatre, and the prison. At the highest part of the city, in the Calle del Paradis, are some magnificent columns and other Roman remains, which, however, are almost hidden by the surrounding buildings.

The public institutions of Barcelona are numerous and important. The university, originally founded in 1430, was suppressed in 1714 by Philip V., and transferred to Cervera; but it was restored in 1841, and is now in a flourishing condition. The education comprises languages, philosophy, jurisprudence, and medicine. There are two academies of literature and science, and several public libraries. The Museo-Salvador, besides a fine collection of objects in natural history, contains a valuable library with a considerable number of scientific MSS., and an archæological collection comprising a rich cabinet of coins and medals; forming altogether the most complete establishment of its kind in Spain. Besides this, there are two smaller museums, and several colleges and educational seminaries. Among these is an admirable institution, with a most extensive scheme of education, comprehending arithmetic and mathematics, modern languages, navigation, experimental philosophy and chemistry, practical agriculture and botany, architecture, painting, sculpture, engraving, mechanics, and commerce. This institution, which is liberally supported by the Board of Trade, affords gratuitous instruction to upwards of 2000 pupils. Among the other important institutions are the *Casa de Caridad* or house of industry, a foundling and deaf and dumb institution, and several hospitals for the sick. The *Montes de Piedad*, or pawnbroking establishments of Barcelona, are, in fact, mutual benefit societies. The *Monte de Piedad de N. Sra. de la Esperanza* has this peculiarity, that loans on deposits are made without interest to necessitous persons. In 1849 the number of persons that availed themselves of its benefits was 5686.

Barcelona ‖ Barclay.

Barcelona is the see of a bishop, the seat of the captain-general of Catalonia, and of an audiencia. It is an important military station, and possesses a naval arsenal, a cannon foundry, and barracks. In a commercial point of view it is the industrial centre of Catalonia. Its trade declined greatly after the emancipation of the Spanish American colonies, but afterwards revived; and notwithstanding the disastrous consequences of the French invasion, it is still the chief commercial emporium of Spain. According to Mr Ford, it is the "Manchester of Catalonia, which is the Lancashire of the Peninsula." The exports consist chiefly of wrought silks, laces, ribbons, calicoes, hats, paper, soap, steel and iron-ware, fire-arms, &c. The chief imports are the produce of America, consisting of cotton, sugar, coffee, cinnamon, indigo, bees' wax, horns, hides, &c. The number ef vessels that entered its port in 1849 was 1896, with a tonnage of 140,369: of these 1372 were Spanish vessels. The harbour is protected on the south by a mole, with a lighthouse and a battery at its extremity. The depth of water within the mole is from 18 to 20 feet; but a bar, which has frequently but ten feet of water, prevents the entrance of large ships. There are consuls here from all the principal states of Europe and America. Population by census of 1842, 121,815. Steamers ply regularly to Marseilles and Cadiz.

The Spaniards ascribe the founding of Barcelona to the Carthaginians under Hamilcar Barca, after whom it was called *Barcino*. It was the theatre of hostilities, both during the Moorish sway in Spain, and in the wars subsequent to that period. During the War of the Succession it adhered to the house of Austria. The seizure of Montjuich, and the subsequent capture of Barcelona by the Earl of Peterborough, formed one of the most brilliant achievements of that remarkable man. At the close of the war it was reluctantly reconciled to the dynasty of the Bourbons. At the commencement of Buonaparte's attempt to seize on the government of Spain, the French troops obtained possession of the fortress; and thus, during the continuance of that war, the city was held in unwilling subjection to the enemies of the cause which its inhabitants most zealously espoused.

Barceloneta, a large suburb to the S.E. of the city, contains 11,000 inhabitants. (Madoz, *Diccionario de España*.)

BARCELONA, *New*, a seaport town, capital of the province of the same name, in Venezuela, South America, founded in 1634. It stands on the left bank of the Neveri, about three miles from the sea. The town is ill-built and unhealthy, but has a considerable trade in horses and cattle. Lat. 10. 6. 52. N. Long. 64. 47. W.

BARCLAY, ALEXANDER, an English poet, generally believed to have been a native of Scotland, though most of his life was spent in England. He is said to have been partly educated in the university of Oxford, and on one occasion makes an allusion to what he had observed at Cambridge. He spent some of his earlier days at Croydon in Surrey; and in 1508 he was a prebendary of the collegiate church of St Mary Ottery

Barclay. in Devonshire. He afterwards became a Benedictine monk of the monastery of Ely, and at length assumed the habit of St Francis at Canterbury. Having survived the dissolution of the monasteries, he became successively vicar of Much-Badew in Essex, and, in 1546, of Wokey in Somersetshire; and was finally presented by the dean and chapter of Canterbury to the rectory of All-Saints in Lombard-street. As he retained some of his preferments in the reign of Edward VI., it is presumed that he must have complied with the changes of the times. Having reached a very advanced age, he died in the year 1552, and was interred at Croydon.

Barclay wrote at a period when the standard of English poetry was extremely low; and, as excellence is always comparative, this circumstance may partly enable us to account for the high reputation which he enjoyed among his contemporaries. If not entitled to the name of a poet, he is at least a copious versifier. His most conspicuous performance is the *Ship of Fooles*, first printed by Pinson in the year 1509. The original design, and many of the details, were derived from Sebastian Brandt,[1] a civilian of Strasburg, who in 1494 published a poem entitled *Das Narren Schyff*,[2] which was so well adapted to the taste of the age that a Latin and a French version appeared in 1497, and another French version in 1498. Barclay professes to have translated "oute of Laten, Frenche, and Doche;" but to the original cargo he has added many fools of English growth. Under the representation of a ship freighted with fools of various denominations, the poet exposes the prevalent vices and follies of the age; and although, as Warton remarks, the poem is destitute of plot, and the voyage of adventures,[3] the general design was found to possess many attractions. Another publication of Barclay is the *Mirrour of good Manners*, translated from the poem of Mancini *De quatuor Virtutibus*. His *Eglogues* chiefly excite curiosity as the earliest specimen of pastoral poetry in the English language, but their other attractions are not very powerful. They are of a more recent date than Henryson's *Robene and Makyne*, and are certainly very inferior in poetical merit. Among his prose works we find a version of Sallust's history of the war with Jugurtha: it was twice printed by Pinson, and is an early specimen of an English translation from the classics. (D.I.)

Barclay, *William*, M. D. was the brother of Sir Patrick Barclay of Tolly,[4] and was likewise related to his learned namesake mentioned in the next article. This latter fact is ascertained by the hendecasyllables subjoined to his notes on Tacitus, and bearing the subsequent inscription: "Nobili et clarissimo viro Guil. Barclayo cognato meo, pro explicato Taciti Agricola, Joannes Barclayus Guil. F. scripsi." The writer of these verses, we may remark, must then have been only seventeen years of age. Barclay prosecuted his studies in the university of Louvain under Justus Lipsius, a great master of Roman literature; and to him this distinguished professor has Barclay. addressed two of his printed letters.[5] He describes himself as A. M. and M. D.; but where he took those degrees we are not informed. Having been appointed a professor in the university of Paris, he there taught humanity for several years, and acquired a considerable share of reputation by his talents and learning. He afterwards visited his native country, where he appears to have followed the medical profession; but it may be inferred from Dempster's brief notice, that, in consequence of his adherence to popery, his situation was rendered uncomfortable by the clergy, and having returned to France, he resumed his former occupation at Nantes in Bretagne.[6] The same literary historian mentions, that, at the period of his writing, Barclay was residing in Scotland, and, according to his information, was pursuing the practice of physic.

The following is a list of all the publications of Dr Barclay with which we are acquainted.

1. Guilielmi Barclayi Oratio pro Eloquentia. Ad v. cl. Ludovicum Servinum, Sacri Consistorii Regii Consiliarium, et in amplissimo Senatu Parisiensi Regis Advocatum. Paris. 1598, 8vo.

2. C. Cornelii Taciti Opera quæ exstant, ad exemplar quod J. Lipsius quintum recensuit. Seorsim excusi commentarii ejusdem Lipsii meliores plenioresque cum curis secundis, et auctariolo non ante adjecto. Guil. Barclayus Præmetia quædam ex Vita Agricolæ libavit. Adjecti sunt indices aliquanto ditiores. Paris. 1599, 8vo.—Menage, in his *Remarques sur la Vie de Pierre Ayrault*, p. 230, has ascribed these *Præmetia* to the civilian, and the same error has been committed by other writers.

3. Nepenthes, or the Vertves of Tabacco. By William Barclay, Mr of Art, and Doctor of Physicke. Edinb. 1614, 8vo.—This tract is dedicated to the author's nephew, Patrick the son and heir of Sir Patrick Barclay of Tolly; and the dedication is preceded by "A merie Epistle of the Author to the Printer," who is no other than "good Master Hart." To this worthy friend he makes the following communication: "If I find fauour in this essay, I shal send you shortly, Godwilling, a scholasticall subiect, and a curious litle worke, fit onely for those which aspire to the top of Pindus. The one wil bring to your shop the common sort of people, the other the most learned." At the end of the tract he has inserted six little poems, the first of which is addressed to Alexander Craig.

4. Guil. Barclayi, Amœniorum Artium, et Medicinæ Doctoris, Judicium de Certamine G. Eglisemmii cum G. Buchanano, pro Dignitate Paraphraseos Psalmi ciiii. Non violandi Manes. Adjecta sunt, Eglisemmii ipsum Judicium, ut editum fuit Londini, typis Eduardi Aldæi, an. Dom. 1619; et, in gratiam studiosæ juventutis, ejusdem Psalmi elegans paraphrasis Thomæ Rhædi. Lond. 1620, 8vo.—Dr Eglisham, like a fair as well as a bold critic, exhibited his own verses in competition with those of Buchanan,

---

[1] Sebastian Brandt, doctor of laws, was born at Strasburg about the year 1458. He studied in the university of Basel; and after having publicly taught there, as well as in his native city, he became syndic of Strasburg, where he died in the year 1520. (Adami *Vitæ Germanorum Jureconsultorum et Politicorum*, p. 5. edit. Francof. ad Moen. 1706, fol.) He is extolled by his contemporary Trithemius as "utriusque juris professor insignis, et tam in divinis Scripturis, quam aliis sæcularis literaturæ disciplinis egregie doctus, poeticam non mediocriter callens, ingenio subtilis, eloquio disertus, consilio ac actione præcipuus." (*De Scriptoribus Ecclesiasticis*, f. ccii. a. edit. Paris. 1512, 4to.) His writings embrace a considerable variety of subjects. We have a copy of one of his professional works, entitled *Titulorum omnium Juris tam Civilis quam Canonici Expositiones*. Lugduni, 1608, 8vo.

[2] See Dr Ebert's *Allgemeines bibliographisches Lexikon*, Band i. S. 230.

[3] Warton's *Hist. of English Poetry*, vol. iii. p. 74.

[4] Dr Barclay has himself mentioned the place of his birth. "Nam Collonia (sic castrum vocatur in quo primum terram tetigi) sita est in littore quod 'tam vasto atque aperto mari pulsatur.' Quo loco, ut obiter dicam, non pauca sunt vestigia veterum bellorum, cum Anglis præsertim. Est in eodem littore, in territorio gentis Barclayanæ, portus quidam, qui nostra lingua *Auld-heauen* appellatur." (*Præmetia*, p. 561.)

[5] Lipsii *Epist. select.* cent. iii. ep. xxxiii. *Epist. cent. ad Germanos et Gallos*, ep. lvi.

[6] "Inde in Scotiam profectus aliquantisper substitit, donec ministri illi Sathanæ magna eum molestia afflicientes solum vertere coegerunt, qui in Galliis iterum docere bonas artes sustinuit Nanneti in Britannia Minore." (Dempster. *Hist. Ecclesiast. Gentis Scotorum*, p. 120.)

Barclay. and had no reason to congratulate himself on the issue. He was likewise assailed by another learned physician, Arthur Johnston, who, in two sarcastic and elegant poems, treated his case as one of decided insanity.

5. Guil. Barclaii, M. D. Poemata. *Delitiæ Poetarum Scotorum*, tom. i. p. 137.—These poems only occupy four pages and a half. (D. I.)

Barclay, *William*, LL. D. a distinguished civilian, was born in Aberdeenshire in the year 1541. He spent the early part of his life, and much of his fortune, at the court of Mary queen of Scots, from whose favour he had reason to expect preferment. In 1573 he went over to France, and at Bourges commenced student of the civil law under the famous Cujacius. He continued some years in that seminary, where he took his doctor's degree; and was soon after appointed professor of the civil law in the university of Pontamousson, recently founded by the duke of Lorraine. That prince afterwards made him counsellor of state and master of requests. In the year 1581 Barclay married Anne de Malleville, a French lady, by whom he had a son, who became a celebrated author, and of whom the reader will find an account in the next article. This youth the Jesuits would gladly have received into their society; but his father refused his consent, and for that reason these disciples of Jesus soon contrived to ruin him with the duke his patron. Barclay now embarked for Britain, where King James offered him a considerable preferment, provided he would become a member of the church of England; but not chusing to comply with this condition, he returned to France in 1604, and, soon after his arrival, was appointed first professor of the civil law in the university of Angers, where he died the year following, and was buried in the Franciscan church.

Barclay was a man of superior talents, and still maintains a conspicuous place among civilians.[1] In his political opinions he was directly opposed to his illustrious countryman Buchanan, and was a strenuous defender of the rights of kings: his own speculations on the principles of government are best known to some readers from an incidental confutation by Locke, in his *Treatises on Government*. A list of his publications shall close this very brief notice.

1. De Regno et Regali Potestate, adversus Buchananum, Brutum, Boucherium, et reliquos Monarchomachos, libri sex. Paris. 1600, 4to.—This volume contains, or ought to contain, a portrait of the author, which however has in many instances been transferred to the portfolio of some collector.

2. In Titulum Pandectarum de Rebus creditis et Jurejurando Commentarii. Paris. 1605, 8vo.—This commentary is reprinted in Otto's *Thesaurus Juris Romani*, tom. iii.

3. De Potestate Papæ; an et quatenus in Reges et Principes seculares jus et imperium habeat: Liber posthumus. Mussiponti, 1610, 8vo.—This work may likewise be found in Goldasti *Monarchia*, tom. iii. p. 621. It was translated into French; and an English version is printed with the treatise of Sheldon, *Of the Lawfulness of the Oath of Allegiance*. Lond. 1611, 4to. Barclay's two treatises, *De Regno* and *De Potestate Papæ*, have repeatedly been printed in the same volume. Hanoviæ, 1612, 8vo. Ha- Barclay. noviæ, 1617, 8vo.

Barclay, *John*, son of the eminent civilian mentioned in the last article, was born at Pontamousson on the 28th of January 1582. He was there educated in the College of the Jesuits, and excited in his instructors so favourable an opinion of his capacity, that they made an attempt to entice him into their order; an attempt which was indignantly resisted by his father. At the age of nineteen, he evinced his literary ambition by publishing annotations on the Thebais of Statius. In 1603, when his father resigned his professorship in disgust, the young and aspiring scholar accompanied him to London; and at the beginning of the following year he presented his *Kalendæ Januariæ* as a poetical offering to King James, to whom he soon afterwards dedicated the first part of his work entitled *Euphormionis Lusini Satyricon*. Both the father and the son were willing to accept of employment, and no doubt they both expected preferment. But, as Lord Hailes has remarked, "William Barclay was conscientiously attached to the church of Rome, and his son professed the religion of his forefathers. In those days a pension bestowed upon a Scottish Papist would have been numbered among the national grievances; and the vulgar would not have distinguished between favour shown to genius or learning, and partiality for the opinions of the person favoured."[2] In the year 1604 they both returned to France, and Dr Barclay was again placed in a situation suited to his talents and learning, having been appointed first professor of the civil law in the university of Angers. His taste for external magnificence appears to have been somewhat prominent: when he went to read his lecture, he was dressed in a superb gown, with a massy chain of gold about his neck, and was followed by his son and two valets.[3]

The younger Barclay, whose hopes of advancement had begun to revive, returned to England in 1605; but after a further residence of twelve months, he still found himself unsuccessful in his pursuit. His father died towards the close of the same year; and he afterwards removed to Paris, where he married Louise, the daughter of Michael Debonnaire, "Trésorier des Vieilles Bandes." He speedily fixed his abode in London, and there his wife bore him a son and two daughters, William, Anne, and Louise. M. de Peiresc, who was himself a man of learning, and was very extensively connected with the learned, found him in this metropolis in the year 1606, and their acquaintance was succeeded by an intimate friendship. During this year he published the second part of his *Satyricon*, which he dedicated to the earl of Salisbury; and likewise a brief narrative of the gunpowder plot, bearing the title of *Series patefacti divinitus Parricidii, in ter maximum Regem Regnumque Britanniæ cogitati et instructi*. In 1610 he published an apology for his *Satyricon*, which had excited so much resentment that he found it necessary to attempt some palliatives and explanations. A tract was published at Paris in 1620, under the title of *Censura Euphormionis*;[4] and this was answered in a *Censura Censuræ Euphormionis*, written by Pierre Musnier, canon of Vezelay.

[3] Menage, *Remarques sur la Vie de Pierre Ayrault*, p. 230.

[4] "On croit, pour le marquer icy en passant, que Séton, Ecossois, est l'auteur de ce petit livre." (Menage, p. 233.) The writer apparently alludes to Dr Seaton, a learned civilian, whom Tomasini enumerates among the eminent scholars of the age. (*Parnassus Euganeus, sive de Scriptoribus ac Literatis hujus Ævi claris*, p. 8. Patavii, 1647, 4to.) Balzac celebrated him in his Latin verses; Scioppius addressed the second epistle of his *Paradoxa Literaria* "Guilhelmo Setonio Scoto Jurisconsulto;" and his name is mentioned with much respect by various other writers of the same period. He is highly extolled in Sir Thomas Urquhart's *Discovery of a most exquisite Jewel*, p. 177. Lond. 1652, 8vo.

Barclay. During the same year, 1610, he published an able work of his father, *De Potestate Papæ*, to which he prefixed a preface of nine pages, concluding with a clear intimation of his purpose to defend his father's memory against any unseemly attack. "Quod si aliquis hoc opus refellere instituet, velim ne oratoria fraude tantum levia quædam carpat, in quibus nec ipse author multum subsidii posuerit; sed ipsam vim rationum excutiat, diluendi aut asserendi vitia accuset. Si quis aliter faxit, sciat Guilielmi Barclaii cineres loqui posse." It was not the object of this treatise to controvert the spiritual supremacy of the pope, which the author was ready to admit in its most orthodox sense; but while he acknowledged his power and jurisdiction in things spiritual, he strenuously contended against his usurped power over sovereign princes in things temporal. The work, which is written with learning and ability, excited no small degree of attention; and it was soon attacked by Cardinal Bellarmin, one of the most formidable defenders of the doctrines of the church, and of the pretensions of its visible head. The son was anxious to evince that the ashes of his revered father were yet capable of speaking. He had not neglected to study the law under so excellent a preceptor; and as he was by no means diffident of his own abilities, he did not shrink from a contest with so redoubtable an antagonist. He accordingly published a large volume bearing the title of *Joannis Barclaii Pietas; sive publicæ pro Regibus ac Principibus, ac privatæ pro Guilielmo Barclaio Parente Vindiciæ, adversus Roberti S. R. E. Cardinalis Bellarmini Tractatum de Potestate Summi Pontificis in Rebus Temporalibus.* Parisiis, 1612, 4to. To this work the cardinal did not himself reply, but an answer was speedily published under the name of *Andreæ Eudæmon-Johannis Epistola monitoria ad Joannem Barclaium de Libro ab eo pro Patre suo contra Robertum Bellarminum S. R. E. Cardinalem scripto.* Col. Agrip. 1613, 8vo.

In 1614 Barclay published at London his *Icon Animorum*, which forms the fourth part of his *Satyricon*. This work is written with talent and vivacity, and may still be perused with pleasure. It is, as Lord Hailes has correctly stated, a delineation of the genius and manners of the European nations, with remarks, moral and philosophical, on the various tempers of men. For the land of his forefathers the author has not failed to testify a sufficient degree of affection. He duly extols the antiquity of the royal line, "inclyto sceptro supra fidem et ætatem regnorum cæterorum." Nor is the literary character of the people left without its share of commendation. "Animi illis in quæcunque studia inclinant, mirifico successu inclyti, ut nullis major patientia castrorum, vel audacia pugnæ, et Musæ nunquam delicatius habeant quam cum inciderunt in Scotos."[1] Some of his sketches of the national character are happy and graphic.

After a residence of ten years in England, Barclay found himself without any sufficient inducement to prolong his stay. To some extent or other, he had experienced the bounty of the earl of Salisbury; and although it does not appear that he obtained any regular provision from the king, we may perhaps suppose that he at least received occasional gratuities; but his resources continued to be scanty, and his situation precarious. Towards the close of the year 1615 he proceeded to Paris, where he had the pleasure of meeting his friend M. de Peiresc, and the honour of being introduced by him to the keeper of the seals, Guillaume du Vair. Having been invited to Rome by Pope Paul V., he there fixed his residence in the beginning of the ensuing year, and by the publication of his next work he endeavoured to prove himself a worthy denizen of this pious city. The work to which we allude is entitled *Joannis Barclaii Parænesis ad Sectarios, libri ii.* Romæ, 1617, 8vo. "It is probable," says Lord Hailes, "that by this exhortation to the sectaries, he meant to give evidence of his own orthodoxy, and to atone for the liberties, almost heretical, which he had taken, as well with the papal court, as with its most faithful adherents. But that court, which had Cardinal Bellarmin for its champion, required not the feeble and suspicious aid of the author of Euphormion.—Although Barclay found much civility at Rome, yet it does not appear that he obtained any emolument. Incumbered with a wife and family, and having a spirit above his fortune, he was left at full leisure to pursue his literary studies. It was at that time that he composed his Latin romance called *Argênis*. He employed his vacant hours in the cultivating of a flower-garden. Rossi (or Erythræus) relates, in the turgid Italian style, that Barclay cared not for those bulbous roots which produce flowers of a sweet scent; and that he cultivated such as produced flowers void of smell, but having variety of colours. Hence we may conclude that he was amongst the first of those who were infected with that strange disease, a passion for tulips, which soon after overspread Europe, and is still remembered under the name of the *Tulipo-mania*. Barclay had it to that excess, that he placed two mastiffs as centinels on his garden; and, rather than abandon his favourite flowers, chose to continue his residence in an ill-aired and unwholesome habitation." The preceding account of his success at Rome is not reconcilable with that of Erythræus, who avers that from Cardinal Barberini he obtained riches as well as civility;[2] but as these benefits are said to have been conferred after the cardinal's elevation to the papal chair, the narrative is liable to some degree of suspicion. The election of Urban VIII. did not take place till the year 1623, and Barclay was then beyond the reach of preferment. It is not however probable that a writer of high reputation, who had been invited by the pope, and was caressed by cardinals, was left without some substantial mark of favour. Bellarmin, whom he had formerly undertaken to refute, was so far from cherishing any resentment, that he honoured him with various marks of kindness.

Barclay died at Rome on the twelfth of August 1621, in the fortieth year of his age. The disease which proved fatal to him was the stone; a disease for which, in his *Satyricon*, he had pronounced the plant called golden rod to be a specific remedy. His remains were interred in the church of S. Onufrio; and at the church of S. Lorenzo, on the road to Tivoli, his widow erected for him a monument, with his bust in marble; but on learning that Cardinal Francesco Barberini had there erected a similar monument in honour of his preceptor, she indignantly caused the bust to be removed. The inscription on Barclay's monument was soon erased; but by whom, or for what reason, is not very clearly ascertained. There is however no improbability in the reason assigned by Freherus, who imputes this act to the vindictive feelings of the Jesuits, an order of men very frequently subjected to his satire.[3]

Barclay. At the time of his death, the romance of *Argenis* was printing under the superintendence of Peiresc,[1] and was soon afterwards given to the public. Paris. 1621, 8vo. Besides a son and two daughters born in England, Barclay had a son who was born at Rome. His elder son is represented by Erythræus as having obtained a rich benefice from Urban VIII. With one of his sons Menage was acquainted at Paris in the year 1652; and, in his opinion, "ce n'estoit pas un grand personnage." Like his father, he was a writer of Latin verses, and at this period he there printed an elegy. We are not aware that the descendants of Barclay are at present to be traced either in France or Italy.

This ingenious writer, who was thus arrested in the middle of his literary career, left an unpublished history of the conquest of Jerusalem by the Franks, and some fragments of a general history of Europe. Erythræus informs us that he had himself transcribed a manuscript tract of his, relating to the defection of M. Ant. de Dominis, archbishop of Spalato; and that from his knowledge of the national character, as well as of the disposition of the king, the author foretold that he could not long remain in England.

The ambition of Barclay was greater than his fortune; nor did his propensity to satirize one class of individuals prevent him from offering abject flatteries to another. But at that period few men of letters knew how to blend self-respect with a proper deference to their superiors in the artificial scale of society. His personal character, with an ample allowance for his vanity as an author, appears to have been respectable. "Some very indecent descriptions in Euphormion," as Lord Hailes has remarked, "lead us to form an unfavourable conjecture as to the manners of Barclay. There is however no proof that he was a loose man; and indeed it is probable that he wrote loosely because Petronius, whom he had chosen for his model in satire, affected that style. Barclay entered into the married state at a very early period of life; and he appears to have continued the fond husband of his *Aloysia*.... There is a presumption, at least, that he who was a good son and a good husband, was also a virtuous man in other respects; and if there had been any remarkable blemish in the morals of Barclay, some of his numerous and virulent adversaries would have pointed it out." He appears to have been subjected to considerable annoyance in consequence of the jealousy of his wife; but in many cases jealousy is a wayward passion, and proceeds from the mere excess of affection, as well as from the knowledge or suspicion of specific and painful facts.

Barclay was evidently a man of genius, and with a vigorous imagination he united a competent share of learning. His literary efforts were sufficiently varied; quitting the regions of poetry and romance, he ventured to discuss subjects of jurisprudence and theology. His Latin poems exhibit marks of fancy and ingenuity, nor is his skill as a versifier less conspicuous.[2] The *Satyricon* is formed on the model of Petronius, and includes occasional verses interspersed with the prose. The talent displayed in this work would alone have been sufficient to secure him a high reputation among the writers of the age; but the fame of all his other productions has in a great measure been eclipsed by that of his *Argenis*, which, after the lapse of two centuries, still finds readers and admirers. "*Argenis*," says Lord Hailes, "is generally supposed to be a history under feigned names, and not a romance. Barclay himself contributed to establish this opinion, by introducing some real characters into the work. But that was merely to compliment certain dignitaries of the church, whose good offices he courted, or whose power he dreaded. The key prefixed to *Argenis* has perpetuated the error. There are no doubt many incidents in it that allude to the state of France during the civil wars in the seventeenth century; but it requires a strong imagination indeed to discover Queen Elizabeth in Hyanisbe, or Henry III. of France in Meleander. On the whole, *Argenis* appears to be a poetical fable, replete with moral and political reflections." This is a sober and correct account of the work; but Cowper has expressed his approbation in more glowing terms. "The work I mean is Barclay's *Argenis;* and, if ever you allow yourself to read for mere amusement, I can recommend it to you (provided you have not already perused it) as the most amusing romance that ever was written. It is the only one indeed of an old date that I ever had the patience to go through with. It is interesting in a high degree, richer in incident than can be imagined, full of surprizes, which the reader never forestalls, and yet free from all entanglement and confusion. The stile too appears to me to be such as would not dishonour Tacitus himself." In another letter he expresses himself thus:—"I have also read Barclay's *Argenis*, a Latin romance, and the best romance that was ever written."[3] This romance was a special favourite with Cardinal Richelieu, and also with Leibnitz, a much greater man than the cardinal. Barclay.

Cowper appears to have been struck with the point and vivacity of his style, which indeed are sufficiently distinguishable; but for the purity of his Latin diction Barclay is not entitled to equal commendation. Being probably impelled by the rapid current of his fancy, he adopts a variety of words and idioms which well express his meaning, but which nevertheless do not belong to the best ages of Latinity. The distich of Grotius, engraved under Barclay's portrait, seems therefore to contain a compliment which must not be too literally interpreted:

Gente Caledonius, Gallus natalibus, hic est
Romam Romano qui docet ore loqui.

Joseph Scaliger, whose literary judgments were frequently severe, and not unfrequently capricious, mentions Barclay's *Satyricon* in terms of great disparagement; but whether his censure is chiefly directed against the Latinity or against the general strain of the work, is not altogether certain.[4] This book, whatever may be its demerits, has passed through many editions, and has been translated into the French and German languages.[5] It has likewise had the advantage of being illustrated with notes. Lugd. Bat. 1674, 8vo. The fourth part, the *Icon Animorum*, has repeatedly been printed in a separate form. One edition bears this inscription: "Joannis Barclaii Icon Animorum, celeberrimi viri Augusti Buchneri notis, adjecto rerum indice, illustrata." Dresdæ, 1680, 8vo. The book soon appeared in an English dress: "The Mirror of Minds, or Barclay's *Icon Animorum;* Englished by Tho. May, Esq." Lond. 1633, 12mo. Of this translation there is another edition in the same form; but the only copy

Barclay. to which we have access contains a mutilated title, and we therefore cannot discover the date. Two French versions had appeared in the course of one year. "Le Pourtrait des Esprits de Jean Barclai, mis en François." Paris, 1625, 12mo. "Le Tableau des Esprits de M. Jean Barclay: par lequel on cognoist les humeurs des Nations, leurs advantages et defaux, les inclinations des hommes, tant à cause de leurs propres naturels que des conditions de leurs charges. Nouvellement traduict de Latin en François." Paris, 1625, 8vo. The dedication of the duodecimo is subscribed Nantevil de Boham; and he has taken such liberties with the original, that his work can scarcely claim the name of a translation. There is a German translation of a very recent date: "Johann Barklai's Gemälde der menschlichen Charaktere nach Verschiedenheit der Alter, Zeiten, Länder, Individuen und Stände: aus dem Lateinischen übersetzt, und mit Anmerkungen und geschichtlichen Nachweisungen begleitet, von Anton Weddige, Pastor zu Lippborg." Münster, 1821, 8vo. A continuation of the *Satyricon* had been published by Claude Morisot, under the title of *Alitophili Veritatis Lachrymæ;* and Lord Hailes describes it as a masterpiece of absurdity.

The editions and versions of the *Argenis* are much more numerous. An edition with notes appeared under the title of "Joannis Barclaii Argenis, nunc primum illustrata." Lugd. Bat. et Roter. 1664, 8vo. This was followed in 1669 by a uniform edition of the continuation: "Archombrotus et Theopompus, sive Argenidis secunda et tertia pars, ubi de Institutione Principis." The notes, which are not held in much estimation, were written by Bugnot, a Benedictine who taught rhetoric in the abbey of Tiron. Lord Hailes mentions a French translation published at Paris, 1622, 8vo; and another with the subsequent title now lies before us: "L'Argenis de Jean Barclay: traduction nouvelle, enrichie de figures." Paris, 1625, 8vo. There are other two French versions of a more recent date, one by the Abbé Josse, a canon of Chartres, 1732, 3 tom. 12mo; and another by M. Savin, Paris, 1776, 2 tom. 8vo. Barclay's romance soon appeared in Spanish; and a copy of this rare version belongs to the Astorga collection in the Advocates Library: "Argenis, por Don Joseph Pellicer de Salas y Tobar. A Don Antonio de Negro, Noble de la Serenissima Republica de Genoua." Madrid, 1626, 4to. Don Joseph has somewhat unfairly excluded Barclay's name from the title-page. An English version was speedily published by Sir Robert Le Grys and Thomas May, Esq. Lond. 1628, 4to. And another was executed by Kingsmill Long, Esq. Lond. 1636, 4to. After a long interval appeared "The Phœnix, or, the History of Polyarchus and Argenis. By a Lady." London, 1772, 4 vols. 12mo. The preface of this publication states that "the editor has made use of both the former translations occasionally, and, whenever a doubt arose, had recourse to the original." Lord Hailes has judiciously enough suggested that "the lady would have done as well had she made use of the original, and only consulted the translations when any doubt arose." The *Argenis* was at an early period translated into German: "Joan. Barclai Argenis, verdeutscht durch Martin Opitzen." Amsterdam, 1644, 12mo. In this country, the version of Opitz is extremely rare; and the only copy that has fallen under our inspection belongs to the writer of the present notice. Another German translation was published by J. Ch. L. Haken. Berlin, 1794, 2 Bde. 8vo. An Italian version was executed by Francesco Pona; and this celebrated romance has even been translated into the Polish, Swedish, and Icelandic languages. Among the northern manuscripts in the Advocates Library there is a *Saga af Argenide*, translated in the year 1694 by a schoolmaster named Einarson.[1] (D. I.) Barclay.

Barclay, *Robert*, one of the most eminent members of the Society of Friends, was born at Gordonstown, in Morayshire, in 1648. He was educated under an uncle at Paris, where every effort was used without success to draw him over to the Popish religion. In 1669 he joined the Quakers, and distinguished himself by his zeal and abilities in defence of their doctrines. In 1676 he published, in Latin, at Amsterdam, his *Apology for the Quakers*, which is the most celebrated of his works, and esteemed the standard of the doctrine of the Quakers. The *Theses Theologicæ*, which were the foundation of this work, and addressed to the clergy generally, were published before the *Apology*, and printed in Latin, French, German, Dutch, and English. The dedication of his *Apology* to King Charles II., is very remarkable for the uncommon frankness and simplicity with which it is written. Amongst many other extraordinary passages, we meet with the following: "There is no king in the world who can so experimentally testify of God's providence and goodness; neither is there any who rules so many free people, so many true Christians; which thing renders thy government more honourable, thyself more considerable, than the accession of many nations filled with slavish and superstitious souls. Thou hast tasted of prosperity and adversity; thou knowest what it is to be banished thy native country, to be over-ruled as well as to rule and sit upon the throne; and being oppressed, thou hast reason to know how hateful the oppressor is both to God and man: if, after all those warnings and advertisements, thou dost not turn unto the Lord with all thy heart, but forget Him who remembered thee in thy distress, and give thyself up to follow lust and vanity, surely great will be thy condemnation." He travelled with the famous William Penn through the greater part of England, Holland, and Germany, and was everywhere received with the highest respect; for though both his conversation and behaviour were suitable to his principles, there was so much liveliness and spirit in his discourse, and such serenity and cheerfulness in his deportment, that he made himself agreeable to all sorts of people. When he returned to his native country, he spent the remainder of his life in a quiet and retired manner. He died at his own house at Ury, on the 3d of October 1690, in the 42d year of his age.

Barclay, *John, M.D.*, a distinguished anatomist, was born in Perthshire in 1760, and died at Edinburgh in 1826. After the usual routine of parochial education, he completed his academical course at the United College of St Andrews. He subsequently studied divinity there, and was licensed as a preacher by the presbytery of Dunkeld. Having repaired to Edinburgh in 1789, as tutor to the family of Sir James Campbell of Aberuchill, he began to give his attention to the study of medicine, and particularly to anatomy, both human and comparative. He became assistant to the late Mr John Bell, and took the degree of M.D. in 1796, after having defended an inaugural dissertation, *De Anima, seu Principio Vitali*, a subject which occupied his maturer powers toward the close of his life. Immediately after his graduation, he repaired to London, and studied for some time under the late Dr Marshall of Thavies Inn, at that time a very distinguished teacher of anatomy in the metropolis. Soon after his return to Edinburgh, he commenced his lectures on anatomy in November 1797; and by his

[1] This translator of Barclay was "Joh. Einari, scholæ primum Skalholtinæ hypodidascalus, deinde rector scholæ Holensis designatus." (Halfdani Einari *Sciagraphia Historiæ Literariæ Islandicæ*, p. 66. Havniæ, 1777, 8vo.) He appears to have been a writer of verse as well as prose.

Bar-cochebas || Bard.

punctual attention to his engagements, and assiduous devotion to the instruction of his pupils, he speedily attracted a respectable audience, which continued gradually to increase in numbers until the period of his retirement, a short time before his death.

Of Dr Barclay's professional writings, the earliest, we believe, was the article PHYSIOLOGY, which he furnished for the third edition of this work.

In 1803, six years after he commenced his career as a teacher, Dr Barclay attempted a reform in the language of anatomy, with a view to render it more accurate and precise; a task for which his acquirements as a classical scholar rendered him peculiarly fit. Although the *Nomenclature* which he published upon that occasion has not been generally adopted, we believe that the profession, with one voice, acknowledges the importance of the object which he had in view, and the talent and learning with which it was executed.

In 1808, he published his *Treatise on the Muscular Motions of the Human Body*, and in 1812 his *Description of the Arteries of the Human Body;* a work displaying much acute observation and laborious research, and which may perhaps be considered the most practically useful of all his writings. His last publication, completed only a few years before his death, was *An Inquiry into the Opinions, Ancient and Modern, concerning Life and Organization;* a work replete with learning and sound original criticism. His introductory lectures, published after his death, contain a valuable abridgment of the history of anatomy.

As a testimony of gratitude to the Royal College of Surgeons of Edinburgh, Dr Barclay bequeathed to that learned and public-spirited body his anatomical collection, now known as the Barclayan Museum, which contains many valuable specimens in comparative anatomy, and some of the finest vascular preparations which are anywhere to be found.

BAR-COCHEBAS, or BAR-COCHAB, a celebrated Jewish impostor, in the second century, whose real name was Simeon. See JEWS and PALESTINE.

BARD, a word denoting a poet by profession. Anciently bards were necessary persons at every festival and at every solemnity. Their songs, which, by recording the achievements of kings and heroes, animated the soul of the hearer, were the entertainment of every warlike nation. We have Hesiod's authority, that in his time bards were as common as potters or joiners, and as prone to envy:—

> Bard, potter, joiner, beggar, 'tis decreed,
> Each with his kind shall never be agreed.

Cicero tells us that anciently at Roman festivals the virtues and exploits of their great men were celebrated in song. The same custom prevailed in Peru and Mexico, as we learn from Garcilaso and other authors. But in no part of the world did the profession of bard appear with such lustre as in Gaul, in Britain, and in Ireland. Wherever the Celtæ or Gauls are mentioned by ancient writers, we seldom fail to hear of their druids and their bards, the institution of which two orders was the capital distinction of their manners and policy. The druids were their philosophers and priests, the bards their poets and recorders of heroic actions; and both these orders of men seem to have subsisted among them as chief members of the state from time immemorial. The Celtæ possessed, from very remote ages, a regular system of discipline and manners, which appears to have had a deep and lasting influence. Ammianus Marcellinus expressly declares, that there flourished amongst them the study of the most laudable arts, introduced by the bards, whose office it was to sing in heroic verse the gallant actions of illustrious men; and by the druids, who lived together in colleges or societies after the Pythagorean manner, philosophizing upon the highest subjects, and maintaining the immortality of the soul. Though Julius Cæsar, in his account of Gaul, does not expressly mention the bards, yet it is plain that under the title of druids he comprehends that whole college or order, of which the bards, who, it is probable, were the disciples of the druids, undoubtedly made a part. According to his account, the druidical institution first took its rise in Britain, and passed from thence into Gaul; so that they who aspired to be thorough masters of that learning were wont to resort to Britain. He adds, too, that such as were to be initiated among the druids were obliged to commit to memory a great number of verses, insomuch that some employed twenty years in this course of education; and that they did not think it lawful to record these poems in writing, but handed them down by tradition from race to race.

Bardas || Bardili.

So strong was the attachment of the Celtic nations to their poetry and their bards, that amidst all the changes of their government and manners, even long after the order of the druids had been extinct, and the national religion altered, the bards continued to flourish, not as a set of strolling songsters, like the Greek ἀοιδοι or *rhapsodists* in Homer's time, but as an order of men highly respected in the state, and supported by a public establishment. According to the testimonies of Strabo and Diodorus, they existed before the age of Augustus Cæsar; and we find them flourishing under that sovereign, and exercising the same functions as of old, in Ireland and in the north of Scotland, almost down to our own times. It is well known that, in both these countries, every *regulus* or chief had his own bard, who was considered an officer of rank and consequence in his little court.

The bards, as well as the druids, were exempted from taxes and military services, even in times of the greatest danger; and when they attended their patrons in the field to record and celebrate their great actions, they had a guard assigned them for their protection. At all festivals and public assemblies they were seated near the person of the king or chieftain, and sometimes even above the greatest nobility and chief officers of the court. Nor was the profession of the bards less lucrative than it was honourable. For, besides the valuable presents which they occasionally received from their patrons when they gave them uncommon pleasure by their performances, they had estates in land allotted for their support. Nay, so great was the veneration which the princes of these times entertained for the persons of their poets, and so highly were they charmed and delighted with their tuneful strains, that they sometimes pardoned even their capital crimes for a song.

BARDAS, the brother of the Empress Theodora, and uncle of the famous Photius. He is said to have had no good quality besides that of loving the sciences and polite literature, which he established in the eastern empire; for otherwise he was treacherous, cruel, and ambitious. In the year 856 he assassinated Theoctistus, general of the Emperor Michael's forces, and obtained his post. At length he caused the disgrace of the Empress Theodora; and when St Ignatius, patriarch of Constantinople, reproached him for his vices, he had the prelate deposed, in 858, in order to make room for Photius. Bardas was assassinated by Basilius the Macedonian in 866.

BARDESANES, a Syrian of Edessa, in Mesopotamia, born about A.D. 154. After his conversion to Christianity he became eminent for his zeal against heretics, and wrote many books against them. He at first embraced the errors of Valentinus, but afterwards laboured to refute them. His followers, who were called Bardesanists, went further than their master, and denied the incarnation of Christ, and the resurrection. His dialogues against Marcion, and his treatise *On Fate*, are much commended. (Euseb. iv. 30; Jerome, c. xxxix.)

BARDILI, CHRISTOPH GOTTFRIED, a German metaphysician, distinguished by his opposition to the system of Kant, was born at Blaubeuren in Wurtemburg, in 1761, and died at Stuttgard in 1808. Of his numerous works the principal is his *Elements of Logic* (*Grundriss der ersten Logik*,

Bardsey ‖ Baretti.

&c.) Stuttgard 1800; in which he has developed his own peculiar views.

BARDSEY, a small island on the Welsh coast, at the northern extremity of Cardigan Bay. It is 2½ miles long by 1 in breadth, with an area of about 370 acres, of which one-third is hilly. The island produces barley and oats. Pop. 90. Its only harbour is on the S.E. side, and admits vessels of 40 tons. The lighthouse has a fixed light 129 feet above high water, in Lat. 52. 45. N. Long. 4. 47. W.

BARÈGES, a small town situated between two mountain chains in the department of Hautes Pyrénées in France, celebrated for its warm sulphurous springs. Their temperature varies from 24° to 36° Reaumur. Upwards of a thousand visitors annually repair to the baths, most of them military men, the benefit of the waters being granted to the army at the expense of government. Their chief value is in cutaneous diseases.

BAREILLY, a large and populous city of Hindustan, and the capital of a district of the same name, is situated on the left bank of the Jooah, a tributary of the Ramgunga. It is a place of some importance with respect both to commerce and manufactures, and, according to the census taken in 1848, has a population of 92,208. The cantonment for the troops is at the south side of the town, and forms the head-quarters for the military division of Rohilcund. Elevation of Bareilly above the sea, 470 feet. Distance from Delhi 152 miles, from Calcutta 788. Lat. 28. 22. Long. 79. 28.

The district of Bareilly is bounded on the N. by Kumaon; on the E. by Oude and Shahjehanpore; on the S. by Budaon, and on the W. by the native state of Rampore and the British district of Moradabad. Its principal rivers are the Gogra, the Western Ramgunga, the Gurrah, and the Goula. The area is 2937 square miles. There are only two cities in the district, viz. Bareilly and Pilleebheet; Aoulah, formerly a larger place than Bareilly, being now in ruins. According to official return, the population amounts to 1,143,657, of which number 883,795 are Hindus, and 259,862 Mahometans and others not Hindu. In summer, notwithstanding the high latitude of Bareilly, the heat is intense; but in winter, water sometimes freezes in the tents. After the devastation of Rohilcund in 1774 by Surajah Dowlah the vizier of Oude, aided by the British troops, the country became a complete waste. Subsequent disturbances called for the renewed interference of the British, and in 1796 the Rohillas were again defeated by the troops under the command of Sir Robert Abercrombie. These events resulted in the transfer of the district of Bareilly to the vizier, by whom in 1802 it was ceded to the East India Company, in commutation of the annual payment agreed to be made to the British government for the maintenance of a subsidiary military force.

The city of Bareilly was in 1816 the seat of a serious outbreak against the British government, which for a time threatened disastrous consequences. It originated in discontent created by certain fiscal arrangements, but was speedily converted by Mahometan fanaticism into a religious quarrel. It was however happily suppressed; but not without a conflict between the government troops and the insurgents, which was followed by the dispersion of the latter. (E. T.)

BARETTI, GIUSEPPE, a native of Turin, was born in 1716. He came to London in 1751, where he became known by the publication of his *Italian Library*, and obtained the appointment of secretary to the Royal Academy, which he retained till his death in 1786. He was the author of an excellent Italian and English grammar, and a valuable dictionary of the same languages; and he afterwards compiled a Spanish and English dictionary. He had the misfortune, in a brawl in the streets of London, to stab a man, who died of the wound. He was tried for his life; and defended himself with great ability. He proved that the homicide had been committed in self-defence from an unprovoked attack; and was acquitted by the jury. On this trial Dr Johnson, Garrick, and Burke, gave favourable testimony to his character, and spoke of him as intimately known to them.

Barfleur ‖ Bark.

BARFLEUR, an ancient town of Normandy, in France, now in the department of Manche, 15 miles E. of Cherbourg. It was ruined and had its harbour filled up by the English in 1346. Cape Barfleur has a lighthouse 271 feet above the sea, in Long. 1. 16. W. Lat. 49. 40. N.

BARGE (*bargie*, Dutch, from *barga*, low Latin), a boat of state or pleasure, sometimes furnished with elegant canopies and cushions, equipped with a band of rowers, and decorated with flags and streamers. There are likewise barges of a smaller kind for the use of admirals and captains of ships of war. These are of a lighter frame, and may be easily hoisted into and out of the ships to which they belong. See BOAT.

BARI, TERRA DI, a province of the kingdom of Naples, bounded on the N. by the Adriatic, E. and S.E. by the province of Otranto, S.W. by Basilicata, and W. by Capitanata. It has an area of 1782 geographical square miles, and is divided into 3 districts and 53 communes. Pop. in 1845, 491,331. Except in the S. and S.W., where branches of the Apennines occur, the surface is generally level. The only considerable river is the Ofanto; this province, however, is the best cultivated in the kingdom, producing abundance of grain, flax, tobacco, cotton, wine, oil, almonds, &c. Swine, asses, goats, and sheep with a very fine wool, are numerous; and the salt and nitre works form important branches of industry.

BARI, the ancient *Barium*, capital of the above province, is situated on a tongue of land projecting into the Adriatic, in Lat. 41. 7. 41. N. Long. 16. 52. 16. E. The town is strongly fortified, but the houses are generally mean, and the streets narrow and filthy. It is the seat of an archbishopric, and has a cathedral, several parish churches, an old priory founded in 1087, a college for the education of nobles, a lyceum, a diocesan seminary, a theatre, arsenal, and several hospitals. The manufactures comprise cotton goods, cloth, hats, soap, glass, &c.; and the liquor called "acqua stomachica" is prepared here. The roads afford good anchorage, with a depth of from 16 to 18 fathoms, but the port is accessible to small vessels only. Pop. 20,000.

BARILLA, the commercial name of an impure carbonate of soda, which is produced by the incineration of several marine and other plants inhabiting the shores of Spain and the Levant, especially those of the genus *Salsola*, which for this purpose are extensively cultivated in the *huerta* of Murcia, and other places on the eastern shores of Spain. Barilla is largely used in the manufacture of glass and soap, and in bleaching. Kelp is an inferior alkali prepared from certain kinds of sea-weed in a similar manner. The manufacture of barilla was introduced into Europe by the Saracens, who called it *kali*; whence, by the addition of the Arabic prefix *al*, came the term *alkali*. Since the introduction of artificial soda (*soude factice*), the importation of barilla has greatly declined. (M'Culloch's *Com. Dict.*)

BARK, the exterior part or skin of trees. Several kinds of barks are met with in commerce, some being used exclusively and largely in the arts, others only in medicine, and a third class as spices. The chief barks met with in commerce are oak bark, mimosa or wattle bark; larch, willow, and alder barks, all chiefly, if not entirely, used in the process of tanning; quercitron bark, used in the production of a yellow dye; cork bark, for the manufacture of corks for bottles, &c.; Peruvian or cinchona bark, cascarilla, and some other barks used in medicine. From the Peruvian bark is prepared the valuable medicine sulphate of quinine, so efficacious in the cure of agues, &c. The other barks occurring in commerce are classed under the head of spices, being

Bark || Barlow.

the cinnamon and cassia barks. With the exception of cinnamon and cassia, barks now pay no import duty. The quantity of bark for tanners' or dyers' use imported in 1852 was 403,930 cwt. Of mimosa or wattle bark, both in its crude state and in the form of extract, we possess no certain information, the custom-house not having published separate and distinct accounts of the imports of each since 1832. In that year, however, the imports of this bark amounted to 28,410 cwt., and have been increasing since that period. Of quercitron bark, the average consumpt amounts to somewhere about 23,000 or 24,000 cwt. annually. In 1852 the quantity of cinchona bark imported amounted to 18,206 cwt., of which 10,092 were re-exported. The quantity of cork bark imported in 1850 amounted to 60,696 cwt. The quantity of cassia bark imported in 1852 amounted to 496,833 lb. It pays an import duty of 1d. per lb. The quantity of cinnamon imported into this country in 1852 amounted to 541,888 lb. Cinnamon pays a duty of 2d. per lb. In 1853 the distinctive colonial and foreign duties were equalized.

BARK, in *Navigation*, a general name given to small ships; it is, however, peculiarly appropriated by seamen to those which carry three masts without a mizentopsail. Our northern mariners who are trained in the coal-trade apply this distinction to a broad-sterned ship which carries no ornamental figure on the stern or prow.

BARKER, ROBERT, the inventor of the modern panorama, and a painter by profession, was born at Kells, in Ireland, in 1740. The first picture of this kind was a view of Edinburgh, which was first exhibited by Mr Barker in that city in 1788. Barker died at London in 1806, having realized a considerable fortune by his invention.

BARKER'S MILL. See HYDRODYNAMICS.

BARKING, a market-town of England, county of Essex, 7 miles E.N.E. of London, on the river Roding, not far from the Thames. It was celebrated for its nunnery, one of the oldest and richest in England, founded about 670, the abbess of which was a baroness *ex officio*. The church of St Margaret is an ancient edifice of considerable beauty, with some curious monuments. It has also an ancient market-house and an embattled gateway. Pop. in 1851, 4930, principally engaged in fishing and the cultivation of vegetables for the London market.

BARLÆUS, or BAERLE, *Gaspar*, professor of philosophy at Amsterdam, and one of the best Latin poets of the seventeenth century, was born in 1584. There was scarcely any event of importance while he lived that was not celebrated by him, when reasons of state opposed no obstacle to it. He was a great defender of Arminius, and showed his abilities in history by his relation of what passed in Brazil during the government of Count Maurice of Nassau, published in 1647. He died in 1648.

BARLETTA, a fortified seaport town of Naples, province of Terra di Bari, 33 miles N.W. of Bari. Lat. 41. 19. 26. N. Long. 16. 18. 10. E. The town is well built and handsome, the houses large, and the streets wide and well paved. It has a fine Gothic cathedral with a lofty spire, a number of churches and convents, an orphan asylum, college, theatre, and a colossal statue of the Emperor Heraclius. The harbour is formed by a mole on which a lighthouse is erected, and it is commanded by the citadel. It is only capable of admitting small vessels, but has a considerable trade in grain, wine, oil, fruit, salt, &c. Pop. 20,000.

BARLEY. See AGRICULTURE and BREWING.

BARLEY-Corn is used to denote a measure, containing in length the third part of an inch. The French carpenters also use barley-corn, *grain d'orge*, as equivalent to a line, or the twelfth part of an inch.

BARLOW, FRANCIS, an English painter, born in Lincolnshire about 1626. On his coming to London he was placed with a portrait painter; but his genius led him chiefly to the drawing of birds, fishes, &c. There are six books of animals from his drawings; and he painted some ceilings with birds for noblemen and gentlemen in the country. His etchings are numerous, but his best work is his illustrations of Æsop. He died in 1702. There is something pleasing in the composition and manner of this painter, though neither is excellent. His drawing is indifferent, nor does he characterize any animal justly. His birds in general are better than his beasts. Barlow.

BARLOW, *Joel*, an American literary and political character of considerable note, was born in the year 1756, in the village of Reading, in Connecticut, the youngest of ten children. His father died when he was yet a boy; and he was sent to the college of Newhaven, in his native state, in 1774. In the course of the prescribed exercises of composition he discovered a taste for poetry, and two productions crept into public view, one entitled *The Prospect of Peace*; the other *An Elegy on the Death of Mr Hosmer*, member of the American congress. It appears that Mr Barlow was destined for the clerical profession; and that his friends solicited and obtained for him the appointment of chaplain to a militia company of Massachusetts, the functions of which he performed till the peace.

At the conclusion of peace between the United States and Great Britain, he abandoned the ecclesiastical life, and settled at the village of Hartford, where, two years afterwards, he published the poem entitled *The Vision of Columbus*.

After quitting the service of the church, he appears for some time to have practised law; but in 1788 he abandoned that profession likewise, and came to Europe as the agent of the Scioto Land Company, a fraudulent association, of whose real character and designs he was ignorant.

Having during this period become deeply interested by the events of the French revolution, he published, in the years 1791 and 1792, several political pieces of a republican character, and in 1793, from motives of curiosity, accompanied the four commissioners of the National Convention who were sent to Mont Blanc to organize that department.

Objects of a commercial nature at length drew him to Hamburg, and afterwards to the coast of Africa, where he received the commission of consul-general of the United States, with instructions to enter into and conclude treaties with the Barbary powers for the purpose of procuring the ransom of the American citizens who were detained as slaves in those countries. The execution of this commission was prompt and successful; and, after residing for some time in Paris, to which he returned from Barbary, he, in 1805, proceeded to America, and purchased a neat habitation in the territory of Columbia, the seat of the general government, to which he gave the name of *Kalorama*. Here he formed an acquaintance with certain influential members of Congress, to whom he greatly recommended himself by the publication of a short sketch of a plan of national education, and an address to the citizens of Washington upon occasion of one of the anniversaries of American independence. He now also published the superb quarto edition of his national poem, to which he finally gave the name of *The Columbiad*. Having returned to the United States, in 1811 he received the appointment of minister-plenipotentiary to the court of France. This nomination met with powerful opposition in the senate, and passed only by a small majority.

The great object of his mission was to obtain compensation for the American property confiscated in virtue of the Berlin and Milan decrees. This arrangement was to be regulated in a manner the least onerous to the French treasury. American ships and cargoes were, at the same time, to be freed from unjust detention, and a new commercial treaty was to be formed on principles of national justice and reciprocity.

Barlow ‖ Barmen.

In pursuit of this object he followed the Emperor Napoleon to Wilna in the memorable winter of 1812; but this diplomatic journey was without advantage, and the failure was the more mortifying, as it was undertaken without the advice or instructions of the American government. Mr Barlow was returning to Paris, when he was seized with a violent inflammatory disease, of which he died on the 26th of December, in the fifty-eighth year of his age; and was interred at Zarnowitch, an obscure village near Cracow.

BARLOW, *Thomas*, was born at Orton in Westmoreland, in 1607. He was appointed fellow of Queen's College, Oxford, in 1633, and two years after chosen reader of metaphysics to the university. He was keeper of the Bodleian library, and in 1657 was chosen provost of Queen's College. After the restoration of Charles II. he was nominated one of the commissioners for restoring the members unjustly expelled in 1648. He wrote at that time *The Case of Toleration in Matters of Religion*, to Mr R. Boyle. In 1675 he was made bishop of Lincoln. After the popish plot he published several tracts against the Roman Catholic religion, in which he showed an uncommon extent of learning, and skill in polemical divinity. Nevertheless, when the Duke of York was proclaimed king, with expressions of affection for His Majesty he veered towards popery; but after the Revolution he as readily voted that the king had abdicated his kingdom, and zealously excluded from their benefices such of the clergy as refused the oaths. He died at Buckden, in Huntingdonshire, on the 8th of October 1691, in the 85th year of his age.

BARLOW, *William*, bishop of Chichester, descended of an ancient family in Wales, was born in the county of Essex. In his youth he favoured the Reformation, and travelled into Germany to be instructed by Luther and other preachers of the new doctrine. He was one of those who, in the transition state of religious opinion in England, veered as the wind blew from the court. In early youth a Protestant, when lured by the possession of rich priories, he was a Papist. In consequence of the readiness with which he resigned these, he was a favourite with Henry VIII., who, in 1547, made him bishop of Bath and Wells. On the accession of Edward VI., he found it convenient to return to his first faith. When Mary succeeded to the crown, he was not prepared for another turn, and was consequently deprived of his bishopric, and imprisoned in the Fleet, where he continued for some time. At length he found means to escape, and joined the English Protestants in Germany. When Queen Elizabeth ascended the throne, he was raised to the see of Chichester, and soon after made first prebendary of the collegiate church of Westminster. He died in 1568, and was buried in the cathedral of Chichester. His five daughters were all married to bishops. He wrote a book upon *Cosmography*, and several other works.

BARLOW, *William*, an eminent mathematician and divine, the son of the bishop of Chichester, was born in Pembrokeshire, whilst his father was bishop of St David's. In 1560 he was entered a commoner of Baliol College, Oxford; and in 1564 took a degree in arts, after which he left the university and went to sea, but in what capacity is uncertain. While at sea he acquired considerable knowledge in the art of navigation. About the year 1573 he entered into orders, and became prebendary of Winchester, and rector of Easton, near that city, and in 1614 he was appointed archdeacon of Salisbury. He was the first English writer on the nature and properties of the magnet, on which he published several treatises. Barlow died in the year 1625, and was buried in the church at Easton.

BARM, or YEAST. See BAKING and BREWING.

BARMEN, a town of Rhenish Prussia, in the government of Dusseldorf, and circle of Elberfeld. It is a long straggling town, stretching along the northern valley of the Wupper, and is formed of the town of Gemarke and several villages. Its manufactures are very extensive, and similar to those of the contiguous town of Elberfeld; which see. Pop. in 1849, 35,984.

Barmouth ‖ Barnard-Castle.

BARMOUTH, a small market-town in the county of Merioneth, North Wales. It is the only port in that division of the Welsh coast, and is much frequented in the summer as a bathing-place. The picturesque scenery in the neighbourhood largely contributes to its attractions.

BARNABAS, ST, one of the earliest apostles of Christianity, was born in Cyprus, and descended of the tribe of Levi. His proper name was *Joses* or *Joseph*, to which, after his conversion to Christianity, the apostles added that of *Barnabas*, signifying either "the son of prophecy" or "the son of consolation." He was educated at Jerusalem under Gamaliel. The time of his conversion is uncertain; but he is generally supposed to have been one of the seventy disciples chosen by our Saviour himself.

At Antioch Paul and Barnabas, in consequence of differing about the propriety of taking with them Mark as their minister on their second evangelizing journey, separated. The subsequent travels and acts of Barnabas are not related in the Acts of the Apostles. Some say that he went into Italy and founded a church at Milan. It is generally believed that he suffered martyrdom at Salamis, where some Jews from Syria set upon him as he was disputing in the synagogue, and stoned him to death. He was buried in a cave near that city by his kinsman Mark, whom he had taken along with him. The remains of his body are said to have been discovered in the reign of the Emperor Zeno, together with a copy of St Matthew's Gospel, written with his own hand, and lying on his breast. The festival of St Barnabas is celebrated on the 11th of June.

BARNABAS, Epistle of, an apocryphal work ascribed to Barnabas, and frequently cited by Clement of Alexandria and by Origen. It was first published in Greek, from a copy of Father Hugo Ménard, a Benedictine monk. An ancient version of it, nearly a thousand years old, was found in a manuscript of the abbey of Corbey. Vossius published it in the year 1646, together with the epistles of St Ignatius; and it has been several times reprinted.

BARNABAS, Gospel of, an apocryphal work ascribed to Barnabas, wherein the history of Jesus Christ is related in a manner very different from the account given us by the four evangelists. The Mahometans possess this gospel in Arabic, and it corresponds very well with those traditions which Mahomet followed in his Koran. It was probably a forgery of some nominal Christians, and afterwards altered and interpolated by the Mahometans, the better to serve their purpose. It has been translated into Italian, Spanish, and English.

BARNABITES, a religious order founded in the sixteenth century by three Italian gentlemen who had been advised by a famous preacher of those days to read carefully the epistles of St Paul. Hence they were called *Clerks of St Paul*, and also *Barnabites*, because they performed their first exercise in a church of St Barnabas at Milan. Their habit was black, and their office to instruct, catechize, and serve in mission.

BARNACLE. See BERNICLE.

BARNACLES, in *Farriery*, an instrument, composed of two branches joined at one end with a hinge, to put upon a horse's nose when he will not stand quietly to be shod, bled, or dressed.

BARNARD-CASTLE, a market-town in the parish of Gainford and Darlington Ward, county of Durham, 247 miles from London, on the banks of the Tees. The corn-market, which is one of the largest in the north of England, is held on Wednesday. The town consists chiefly of one long and spacious street, the chief ornament of which is a handsome octagonal market-cross. Its principal manufactures are carpets and thread. Pop. in 1851, 4357. This

Barhaul || Barnstaple.

town derives its name from a castle founded about the year 1180 by Barnard Baliol, an ancestor of the competitor with Bruce for the Scottish crown. The remains of the castle extend over a space of more than six acres.

BARNAUL, a mining town of Siberia, situated on a river of the same name, near its junction with the Obi. It is the capital of an extensive mining district, and the seat of a board of administration. Large quantities of gold, silver, copper, and iron ores are smelted here. Pop. about 10,000.

BARNES, JOSHUA, an eminent English scholar, was born about the middle of the seventeenth century. In 1695 he was chosen queen's professor of Greek, a language which he wrote and spoke with the utmost facility. His first publication was a whimsical tract entitled *Gerania*, or a new discovery of the little sort of people called Pygmies. He also wrote a *Life of Edward III.*, in which he introduces his hero making long and elaborate speeches, besides several other books, particularly *Sacred Poems;* the *Life of Oliver Cromwell the Tyrant*; some dramatic pieces; a poetical paraphrase on the history of Esther, in Greek verse, with a Latin translation, &c. He also published editions of Euripides, Anacreon, and Homer's Illiad and Odyssey, with notes and a Latin translation. He wrote with even greater facility in Greek than in English, and yet he is generally allowed not to have understood the niceties of that language. He died in 1712, in the 58th year of his age.

BARNET, or CHIPPING BARNET, a market-town in the hundred of Caisho, and county of Hertford, 11 miles from London, on the great northern road. Near it, in 1471, was fought the decisive battle between the houses of York and Lancaster, in which the great Earl of Warwick fell. The market, held on Monday, is large; as it has great cattle fairs. Pop. of parish in 1851, 2380.

BARNEVELDT, JAN D'OLDEN, a celebrated Dutch statesman, and one of the founders of the civil liberty of Holland, was born at Amersfoort in 1547. His patriotic zeal having led him to limit the authority of Maurice Prince of Orange, the second stadtholder of Holland, the partisans of that prince falsely accused him of a design to deliver his country into the hands of the Spanish monarch. On this absurd charge he was tried by 26 commissaries deputed from the Seven Provinces, condemned, and beheaded at the Hague in 1619. His sons, William and Réné, with the view of avenging their father's death, formed a conspiracy against the stadtholder, which was discovered. William fled, but Réné was taken and condemned to die; which fatal circumstance has immortalized the memory of his mother, of whom the following anecdote is recorded. She solicited a pardon for Réné; upon which Maurice expressed his surprise that she should do that for her son which she had neglected for her husband. To this remark she replied with indignation, "I would not ask a pardon for my husband, because he was innocent; I solicit it for my son because he is guilty."

BARNSLEY, or BLACK BARNSLEY, a town in the parish of Silkstone, of the wapentake of Staincross, in the West Riding of Yorkshire, 171 miles from London. It formerly had considerable manufactures in iron, but it has of late years become the seat of extensive factories of linen and other cloth. The trade has been greatly increased in consequence of the extension of canal navigation, which connects the town with Wakefield, and the other canals and navigable rivers which unite at that place. There is a large market every Wednesday for cattle and corn. Pop. in 1851, 13,437.

BARNSTAPLE, a market, seaport, and borough town of England, county of Devon, 34 miles N.W. of Exeter. It is a handsome and well-built town, standing on the river Taw, 6 miles from its mouth. This stream, which is only navigable for small craft, is here crossed by an ancient stone bridge of 16 arches. The town was incorporated in the reign of Henry I., and is governed by a mayor, 6 aldermen, and 18 councillors. It has returned two members to parliament since the time of Edward I. The woollen trade, for which it was once famous, has now much declined; but it has extensive potteries and tanneries, &c. The public buildings and institutions include a large church, guildhall, theatre, free grammar school, mechanics' institute, national and charity schools, an infirmary, and dispensary. The poet Gay was born in the vicinity, and received his education at the grammar school here. Pop. in 1851, 11,371.

Barnstaple || Baroco.

BARNSTAPLE, a seaport town, and capital of the county of the same name, in the state of Massachusetts, North America. It is situated on the south side of a bay of the same name, which opens into Cape Cod Bay. In 1848 it had 64,309 tons of shipping, of which about 30,000 tons were employed in the coasting trade, and about 16,000 in the cod and mackerel fisheries. Pop. 4301.

BARO, or BARON, PETER, professor of divinity in the university of Cambridge in the sixteenth century, was born at Estampes, in France, and educated in the university of Bourges, where he was admitted a licentiate in the law; but being of the Protestant religion, he was obliged to leave his native country in order to avoid persecution. After residing some time at Geneva, he came to England, and was kindly received by Lord Burleigh. He afterwards settled at Cambridge, and, by the recommendation of his noble patron, in 1574 was chosen Lady Margaret's professor there. For some years he enjoyed his professorship in quiet; but a restless faction was at last raised against him by his opposing the doctrine of absolute predestination; and this rendered his situation so uncomfortable that he chose to leave the university and settle in London. He wrote *In Jonam Prophetam Prælectiones xxxix.; De Præstantia et Dignitate Divinæ Legis;* and some other treatises. He died in London about the year 1600.

BAROCCHIO, or BAROZZI, *Giacomo da Vignola*, a celebrated architect, born at Vignola, in the Modenese territory, in 1507. He succeeded Michael Angelo as the architect of St Peter's, and executed various portions of that fabric, besides a variety of works in Rome and other parts of Italy. He is the author of an excellent work on the *Five Orders of Architecture*. His character as a man was worthy of his genius; for to his extensive acquirements and exquisite taste was superadded an amenity of manners and disposition, and a noble generosity, that won the affection and admiration of all who knew him. Da Vignola died in 1573, at the age of sixty-six.

BAROCCI, or BAROCCIO, FREDERIGO, a celebrated painter, born at Urbino, where the genius of Raphael inspired him. In his early youth he travelled to Rome, where he painted in fresco. He then returned to Urbino, and giving himself up to intense study, acquired great fame as a painter, particularly of religious subjects. He also etched from his own designs a few prints, which are highly finished, and executed with great softness and delicacy. He died a Urbino in 1612, aged 84.

BAROCO, in the *Old Logic*, a term given to the fourth mode of the second figure of syllogisms. A syllogism in baroco has the first proposition a universal affirmative, but the second and third particular negatives, and the middle term is the predicate in the first two propositions. For example,

Nullus homo non est bipes:
Non omne animal est bipes:
Non omne animal est homo.

BAROMETER.

Barometer. Our dictionaries contain such an account of the discovery and construction of this most valuable instrument, as can be drawn from the popular treatises of natural philosophy in the English language. But, unfortunately, the compilers of elementary works have seldom taken the trouble to remount to the original sources of information, and have frequently, by substituting their own fancies, or servilely copying the mistakes of others, contrived to disfigure egregiously the relation of facts, and the history of the progress of invention. We purpose, therefore, as far as our limits will admit, to discuss the subject with more careful research; but, passing rather lightly over the description of the different kinds of barometers and other practical details, to dwell more especially on the successive steps which led to the fine discovery of atmospheric pressure and its application to physical science.

Opinions of the ancients; The opinions entertained by the ancients concerning physical subjects appear at best only splendid visions. They speculated boldly in cosmological theories, but were easily satisfied with those conclusions which merely soothe the fancy. Many of the philosophical notions adopted in remote ages have, however, left a durable impression in the structure of language, and still continue to exercise a visible influence in moulding the current sentiments of mankind. The early sages of Greece distinguished matter into the four primary elements, of *earth*, *water*, *air*, and *fire*, which, by their various combinations, were supposed to produce the animated spectacle of the universe. With these elements were associated corresponding qualities, in a binary conjunction; *hot* and *cold*, *dry* and *moist*. *Earth* and *water* were considered as ponderous and inert; but *air* and *fire*, endued with elastic virtue, were imagined to possess lightness and activity. *Fire*, though extracted from all bodies by the operations of nature or of art, was yet conceived to be derived, by invisible emanation, from that diffuse lambent fluid which, under the name of *Æther*, occupied the highest heavens, and furnished the substance and nutriment of the celestial bodies. While the earthy matter would, therefore, naturally settle towards the centre, and the aqueous fluids roll along the surface of the solid globe, the air and fire soared aloft; the former occupying the whole of the region below the moon, and the latter streaming through the boundless extent of space. This *sublunary* scene is exposed to incessant change, calamity, and decay; but above it was supposed to reign a perpetual calm, the seat of bliss, and of divine and imperishable essence.

Aristotle and some other philosophers, viewing *æther* as altogether distinct from *culinary fire*, were disposed to consider it as a *fifth* element, of a pure, divine, and incor-
and of the schoolmen. ruptible nature; an opinion which afterwards gave occasion to the famous *Quinta Essentia*, or *Quintessence* of the schoolmen. The alchemists, who sprung up nearly about the same benighted period, in adopting these notions, modified them to suit their own peculiar views. To the elements commonly received, they joined the active auxiliaries of *mercury* and *sulphur*. For *quintessence* they substituted *spirit* and *elixir*; the former, drawn off by the application of fire, being conceived to represent the animating principle of each body; while the latter, extracted by the combined action of heat and moisture, was supposed to exhibit its concentrated and most select qualities.

Some of the ancient cosmologists imagined a vacuum beyond the shining expanse of æther, destined to receive the exhalations from this nether world. Others denied Barometer.
the existence of a separate void, but admitted small vacuities interspersed through bodies. Aristotle, however, Physical
maintained the necessity of a plenum, asserting that our tenets of
idea of space or extension is inseparable from that of Aristotle.
body. To this principle he ascribed the suspension of water in a tube, when the finger is applied to shut the upper end. Yet the very contempt in which that philosopher, from a consciousness of his own superiority, was accustomed to hold the received opinions, might have led him to take juster views. He rejected the notion that air has levity inherent in its nature; nor would he admit the more plausible idea, that a fluid so easily moved must possess the quality of perfect indifference, and be neither light nor heavy. Aristotle not only maintained that air is ponderous, but did not scruple to appeal to direct experiment in support of this assertion. A bladder, he says, will be found to gain some weight, on being blown or filled with air. But this was evidently a mere random assertion, betraying his ignorance of the constitution of fluids. A bag filled with air, and suspended in a like medium, it is obvious, from the laws of hydrostatics, must weigh exactly the same as before. If it be alleged that, in blowing up the bladder, a portion of air would be introduced immediately from the lungs, and containing therefore a small admixture of carbonic acid gas, which is specifically heavier than the common atmospheric fluid; the additional weight, amounting scarcely perhaps to a grain, would be too minute to be detected by any of the jewellers' balances constructed in ancient Greece.

The mutual opposition of the leading philosophical sects of antiquity had, in general, most fatally discouraged the application of mathematical reasoning to the system of the material world. The Academicians, or the disciples of Plato, who cultivated geometry with ardour and brilliant success, were disposed to regard that science as a pure intellectual contemplation; and resigning themselves to the illusion of their lofty dreams, they turned with disdain from the investigation of individual facts and all the vulgar realities of life. The mind of Aristotle was of a more sober and practical cast; acute, profound, and discriminating, it ranged with incredible industry over an immense field of inquiry. That judicious philosopher recommended a careful and constant appeal to external observation, as the only sure ground on which to erect the structure of physics; but unfortunately his scholars neglected too much the study of mathematics, the most powerful instrument for conducting physical research. The precepts of Aristotle, though excellent in some respects, were hence in the sequel unproductive of any genuine fruit. On the contrary, the weight of his opinions, during a long course of ages, repressed the efforts of human genius.

It must be gratefully acknowledged, that the alche- Modern
mists, styled also *philosophers by fire*, were the first among experi-
the moderns who dared to explore new paths of science. mentalists
Their projects were, indeed, highly chimerical, but they had the merit at least of setting the example of investigating the properties of matter by actual experiment. They likewise formed associations among individuals for the more effectual prosecution of such researches. Hence the origin of that obscure sect known by the fanciful title of *Rosicrucians*, who sprung up in Germany, and insensibly spread their influence over the Continent. Those principles were afterwards transplanted into the matured

Barometer. soil of Italy, where philosophy, succeeding to the cultivation of letters, wore a more attractive garb. Baptista Porta, a Neapolitan nobleman, who flourished about the latter part of the sixteenth century, was particularly distinguished by his zeal in promoting such pursuits. Having spent many years in travelling over Europe to gain information respecting natural objects, he invited a few individuals of a congenial taste to assemble at stated times in his house, and assist him in making new experiments. These meetings, however, gave umbrage to the watchful jealousy of the clergy, and they were soon suppressed by a mandate from the court of Rome. But the example was imitated in other parts of Italy, where the papal authority enjoyed less respect; and academies for the promotion of natural science were successfully instituted under the patronage of different princes, especially those of the illustrious house of Medici.

Galileo. In this ferment of inquiry, Galileo arose, a man fitted alike by the gifts of nature and the lights of education to be the founder of experimental science. His elegant genius was invigorated by the study of the Greek geometry; and he conceived the happy and prolific idea of employing that refined instrument to explore facts and combine the results. Archimedes, indeed, among the ancients, had anticipated this road of discovery, having most successfully applied the powers of geometrical analysis to the investigation of some parts of mechanics and hydrostatics. But his was a solitary instance, unheeded by succeeding ages. The ingenuity of Galileo prepared a complete revolution in science. By means of a few simple but striking experiments performed on the lagoons of Venice, he established the laws of motion, which he now transferred from the surface of our globe, to direct the revolutions of the heavenly bodies. The publication of his *Dialogues*, which unfold the right process of induction, and are not less distinguished by fineness of conception than beauty of diction, forms a new era in the annals of philosophy. He was the first who attempted to ascertain the weight of air by actual experiment; and considering the nicety of the operation, and the rudeness of the instruments constructed at that period, he made a very tolerable approach to the truth. It had been known for many ages that air is capable of being highly condensed; and Ctesebius of Alexandria had invented an engine, which, by the force of the sudden expansion of this compressed fluid, hurled missile weapons. This was afterwards improved into the wind or air-gun, which seems to have been not uncommon in Europe as early as the fifteenth century, though soon afterwards generally superseded in practice by the introduction of fire-arms. Galileo, being led by a different path from that pursued at present, set himself to examine the weight which air acquires by condensation. Having fitted a large copper ball with a valve, he injected air into its cavity by means of a syringe, and then suspended it to a balance. The additional increase of weight being thus found, he opened the valve under an inverted glass receiver full of water, and measured, by the displacement of this liquid, the surplus quantity of air which had been injected into the copper vessel.[1] He thence concluded that air is 400 times lighter than water, being about the double of the true estimate; an error probably arising from some imperfection of the valve that confined the air within the ball. Barometer.

After he had, by such researches, acquired celebrity in the scientific world, Galileo accepted an invitation, with a very handsome appointment, from Cosmo de' Medici; and devoting himself intensely to astronomical observations, aided by the telescope, which, from an obscure hint, he had recently constructed, yet occasionally unbending his mind with elegant recreation, he spent almost the whole of the evening of his life at the villa of Arcetri, near Florence, in a style of comfort and even splendour. But, while occupied with those delightful pursuits, exploring the planetary phases, and discovering new worlds, he was for a moment recalled to his early studies by an incident destined to form an epoch in the history of physical science. Some artisans, in the service of the grand duke, having been employed to construct a lifting or sucking pump for a very deep well, found, with equal surprise and vexation, that, in spite of all the pains they had taken in fitting the piston and valves, the water could by no effort be made to rise higher in the barrel than eighteen palms, or thirty-two feet. In this dilemma they applied to Galileo for an explication of the cause of a failure then so unexpected and perplexing. But the philosopher was not yet prepared to encounter such a discordant fact. The Aristotelian tenet of the impossibility of the existence of a void, was, at this period, universally received as an unquestionable truth. It had become a favourite axiom of the schoolmen, deceiving themselves, as Leibnitz did afterwards in proposing his principle of *sufficient reason*, by the glimmer of a metaphorical expression, the *fuga vacui*, or *nature's horror of a void*. To create a vacuum, they gravely maintained, would require the hand of Omnipotence, transcending the utmost power of men or even devils. But Galileo, though borne along by the current of opinion, saw the necessity of at least modifying the general principle. Without questioning nature's abhorrence of a vacuum, he supposed the influence of this horror to be confined within certain limits, not exceeding the pressure of a column of water eighteen palms in height. This was evidently evading, rather than meeting, the difficulty proposed for his solution. Yet, in the last of his Dialogues, he actually mentions an experiment to ascertain this power, or *virtù*, as he calls it, of a vacuum. A piston with a valve, exactly fitted into a smooth hollow cylinder, was rammed quite to the end, and this carefully shut up; then placing the cylinder in an upright but inverted position, successive weights were appended to the rod, till it was drawn from the close end, and pulled down. It may seem strange that the Tuscan philosopher, after advancing so far, should have stopt on the verge of a great discovery. He had already weighed the air, and it was only another small step thence to infer the effect of its incumbent mass. But the atmosphere was still believed to reach to the moon, and the pressure of columns of such enormous altitude seemed to mock all calculation, and overwhelm the imagination.[2] Yet, on reconsidering the subject, Galileo began to suspect the solidity of the explication which he had given; but it was now too late for

Incidental failure of a sucking pump.

Timid and imperfect explication of Galileo.

[1] From this remarkable experiment it is easy to perceive that Galileo was really the inventor of our pneumatic apparatus, though his title has been so long overlooked by chemists.

[2] This narrative, which marks so well the slow and timid steps whereby men, even of the highest intellectual endowments, usually advance in the search after truth, is drawn from the writings of Galileo himself. The carelessness of some authors in mis-stating facts, and imputing unworthy motives to those patriarchs of science who could not open their eyes all at once to the bright effulgence of day, deserves severe reprehension. We may remark, in passing, that M. Biot, who ranks among the first mathematicians and philosophers in France, has not scrupled, in an elaborate compilation on physics, to allege that Galileo merely joked with the artisans who asked him the reason of the failure of their pump; that he had an idea of the true explication, but chose to keep his secret, and suffer it to die with him. Such conduct would certainly have been a reproach to Galileo's acknowledged candour.

Barometer. him, in his advanced age, loaded with bodily infirmities, and dispirited by clerical persecution, to attempt any further innovation in science. Recommending it earnestly to his friend and pupil Torricelli to resume the investigation, this illustrious precursor of Newton expired in 1642, the very year in which the English philosopher was born. His uniform kindness and urbanity rendered him extremely beloved; and his disciples, particularly Torricelli, Viviani, and Ricci, venerating his memory, caught the same taste, and followed similar pursuits.

Torricelli's famous experiment.

Torricelli now conceived the happy idea of exhibiting the action of a pump on a contracted scale, by means of a column of mercury, which is nearly fourteen times heavier than water. This experiment he first communicated to his friend Viviani, who performed it with success in 1643; and he afterwards repeated and varied it himself. The method which he adopted brought very neatly under one view all the circumstances affecting the question. Having selected a tube about a quarter of an inch wide, and four feet long, he sealed one of the ends hermetically, or closed it under the flame of a lamp; he then filled the cavity of the tube with mercury, and applying his finger to the open end, he inverted it in a basin likewise containing mercury, though covered with a portion of water. The mercury instantly sunk to nearly thirty inches above the lower surface; but on raising the tube, till its orifice communicated with the layer of water, the mercury ran all out, and the water now sprung up to the top, and occupied the whole of the cavity. It was thus proved, that the water and mercury are each supported by the same equipoise, which Torricelli, after some hesitation, at last concluded to be the pressure of the external atmosphere. He next converted the mercurial column into a form adapted for observation, by bending the lower end of the tube, and constructing what has since received the name of the *siphon barometer*. (See fig. 1. Plate CIV.) Thus provided with a commodious instrument, he soon detected the variation of atmospheric pressure, which depends on the change of weather. These important results were published in the year 1645; but Torricelli did not live to enjoy the fame of his great discovery, for this most promising genius was snatched away by a putrid fever in the flower of his age.

The report of Torricelli's first experiments having been carried to France before he had ventured to draw his capital conclusion, set philosophers to speculate on the cause of such an unexpected fact. Descartes, with his usual rapidity and boldness of conception, did not hesitate, in his correspondence with Mersenne, to refer the suspension of the mercury in the tube at once to the pressure of the external atmosphere. But this inference appears not very consistent with his system, which assumed the existence of an absolute plenum, and only supplied the place of a void by the diffusion of subtile abraded particles of matter. He suspected, besides, the accuracy of Galileo's estimate of the weight of the air, which he thought could be scarcely appreciable by experiment.

Pascal's experiments.

But, in the same country, the subject was now pursued with deliberate caution, and through all its details, by another genius of the highest order; one of the finest and most original that France has ever produced. Pascal had shown premature and extraordinary talents, which were encouraged by his father, a man of learning, who lived in habits of intimacy with the literati of Paris. The young philosopher happened to be residing at Rouen, in 1646, when he was informed of the famous Italian experiment. Having access, fortunately, to a glass-house, he resolved immediately to repeat the observations on a large scale. He had already suspected the justness of the principle, that "nature abhors a vacuum," and thought that the condensation and rarefaction of the air point to a different, or at least a modified conclusion. With a view to clear up this subject, Pascal performed a number of satisfactory experiments, of which we shall cite a few of the more striking, nearly in his own language, tinctured evidently with the prevailing opinions of the age:—1. Having fitted a piston to an open glass tube, and rammed it quite down, he applied his finger close to the lower end, and plunged the whole under water; then drawing back the piston, which was done with ease, the finger felt strongly and rather painfully *attracted*, while an *apparent vacuity* was formed above it, and continued to enlarge; but instantly on removing the finger, the water, *contrary to its nature*, darted up and filled the whole of the cavity. 2. A glass tube, about fifty feet long, sealed hermetically at one end, and filled with water, or rather red wine, as a more visible fluid, was inverted perpendicularly in a basin of the same. The liquid immediately subsided, leaving a vacant space of thirty-five feet; but on gradually reclining the tube the liquid rose again, and continued to mount till it struck a sharp blow against the top of the glass. 3. A siphon, having one leg fifty-five feet high, and the other only fifty, being filled with water, and planted in two basins containing the same, such that the shorter branch had a perpendicular position, the water sunk in both to the same level, without being *attracted*, as usual in siphons, to the longer branch; but, on leaning the siphon back the columns rose till they united at the top, and then the water began to flow towards the lower basin. The same experiment was also performed with mercury, the siphon having one leg ten feet, and the other only nine feet and a half in length, the mercury being found to divide itself into two columns, which continued suspended at an altitude of about thirty inches. 4. Having nicely fitted a piston to a long glass syringe, and pushed it down to the end, he immersed this in a basin of mercury, and held the tube in a vertical position; on gently drawing up the piston, the mercury closely followed it to the height of twenty-nine inches, but then stopt, leaving the piston to form above it an apparent vacuity. In this state, also, the syringe weighed exactly the same, whatever was the magnitude of the vacant space.

His cautious induction.

From these and other similar experiments, Pascal led his inductive process, with a degree of caution that might seem to border on timidity. He inferred that all bodies have a *reluctance* to a visible separation, or that nature abhors an apparent void; that this reluctance is exactly the same for a small as for a great vacuity; and that the force is limited, and exceeds not the pressure of a column of water thirty-three feet in height. He next ventured one step farther, and concluded, that this apparent vacuity was not filled by air lodged in the pores of the glass, or derived from external filtration; that it contained no subtile matter secreted from the atmosphere, and was not occupied by mercurial vapours or spiritous exhalations; in short, that a real and absolute vacuum had been formed.

Attacked by Noël.

Pascal, then only twenty-four years of age, proposed to write a treatise on the subject of those inquiries; but thought proper, in the mean time, to publish a short abstract of it, which appeared in 1647, and involved him in a wretched controversy. Father Noël, rector of the Jesuits' College at Paris, keenly attacked it, armed with all the miserable sophisms of the schools, and the absurd dogmas of the Romish church. He contended, that the space above the mercurial column was corporeal, because it was visible and admitted light; that a void being a mere non-entity, cannot have different degrees of magnitude; that the separation produced in the experiments was violent and unnatural; and he presupposed that the atmosphere, like blood, containing a mixture of the seve-

Barometer. ral elements, the fire and the finer part of the air were detached from it, and violently forced through the pores of the glass, to occupy the deserted space. To enforce these puerile arguments, the reverend prelate did not scruple to employ the poisoned weapon which his order has often wielded with deadly effect, namely, hinting an oblique charge of heresy. This rude attack only roused Pascal, and disposed him boldly to throw off the fetters of inveterate opinion. He began to perceive that "*abhorrence*" cannot, in strict logic, be applied to nature, which is a mere personification, and incapable of passion; and was inclined, by degrees, to adopt the clear disembarrassed explication of Torricelli, referring the suspension of the mercurial column to the pressure of the external atmosphere. In stating this conclusion, he makes some remarks which would deserve the serious attention of philosophers in the present age. "When the weakness of men is unable to find out the true causes of phenomena, they are apt to employ their subtilty in substituting imaginary ones, which they express by specious names that fill the ear, without satisfying the judgment. It is thus that the sympathy and antipathy of natural bodies are asserted to be the efficient and unequivocal causes of several effects, as if inanimate substances were really capable of sympathy and antipathy. The same thing may be said of the antiperistasis, and various other chimerical causes, which afford only a vain relief to the avidity of men to know hidden truths, and which, far from discovering them, only serve to conceal the ignorance of those who invent such explications, and nourish it in their followers." These remarks, equally judicious and profound, are the more striking, since Lord Bacon, while he proposed to reform and new-model the whole structure of human learning, yet complied with the taste of his age in retaining much of the jargon and barbarous distinctions of the schools.

Pascal's decisive experiment.

But Pascal did not rest satisfied with mere reasoning, however strictly conducted; and he soon devised an experiment which should palpably mark, under different circumstances, the varying effects of atmospheric pressure. It occurred to him, that, if the mercury in the Torricellian tube were really supported by the counterpoising weight of the atmosphere, it would be affected by the mass of superincumbent fluid, and must therefore partially subside in the higher elevations. He was impatient to have his conjecture tried in a favourable situation; and, in November 1647, he wrote a letter communicating those views to his brother-in-law, Perier, who held an office of considerable trust in the province, and commonly resided at Clermont in Auvergne, in the immediate vicinity of the Puy de Dôme, a lofty conical mountain, which rose, according to estimation, above the altitude of 500 toises. Various avocations, however, prevented that intelligent person from complying with his instructions till the following year. Early in the morning of the 19th September 1648, a few curious friends joined him in the garden of a monastery, situated near the lowest part of the city of Clermont, where he had brought a quantity of mercury, and two glass tubes hermetically sealed at the top. These he filled and inverted, as usual, and found the mercury to stand in both at the same height, namely, 26 inches and $3\frac{3}{4}$ lines, or 28 English inches. Leaving one of the tubes behind, in the custody of the subprior, he proceeded with the other to the summit of the mountain, and repeated the experiment, when his party were surprised and delighted to see the mercury sink more than three inches under the former mark, and remain suspended at the height of 23 inches and 2 lines, or 24·7 English inches. In his descent from the mountain, he observed, at two several stations, that the mercury successively rose; and, on his return to the monastery, he found it stood exactly at the same point as at first. Encouraged by the success of this memorable experiment, Perier repeated it on the highest tower of Clermont, and noted a difference of two lines at an elevation of twenty toises. Pascal, on his part, as soon as the intelligence reached him at Paris, where he then chanced to be, made similar observations on the top of a high house, and in the belfry of the church of St Jacques des Boucheries, near the border of the Seine; and so much was he satisfied with the results, that he proposed already the application of the barometer for measuring the relative altitudes of distant places on the surface of the globe. Barometer.

The investigation of the existence and effects of atmospheric pressure was now completed, and it threw a sudden blaze over the whole contexture of physical science. The fame of the experiments performed in Italy and in France, quickly spread over Europe. Yet such is the force of habit and early prejudice, that, after the first moments of surprise and confusion, few of the learned at this period had the courage to open their eyes to the light which had so unexpectedly burst upon them; but, secretly cherishing their inveterate notions, they sought to comfort themselves by starting a variety of captious objections. Father Mersenne, though a man of some abilities, conceived that suction was occasioned by certain hooked particles dispersed through the atmosphere, which laid hold of any fluid in contact with them, and drew it towards the general mass. Father Linus, plunging still deeper in mysticism and absurdity, gravely proposed the *funicular hypothesis*, which attributes the suspension of the mercurial column to the agency of certain small invisible threads. But others of the clergy attacked Pascal with envenomed bitterness. The Jesuits of the college of Montserrand scrupled not, in their public theses, to pervert his expressions, and even contest the originality of his experiments. The philosopher was justly incensed at their base conduct; and those repeated provocations served, no doubt, to give a keener edge to his wit, when he afterwards directed it with such overwhelming force against that insidious and formidable order of priesthood. He composed in 1653, though they were not published till after his death, two short treatises, *On the Equilibrium of Liquors*, and *On the Weight of the Mass of Air*, remarkable for their neatness, perspicuity, and lucid order. The laws of the equilibrium of fluids are there beautifully deduced from a single principle, which suggests a variety of original views and admirable remarks. In those tracts he likewise gives a description of the Hydraulic Press, a most useful and powerful machine, which has lately been revived in this country, and by some considered as a new invention. Opposition which it experienced.

A similar discovery, which was made about the same time in Germany, came seasonably to support the triumph of innovation. Otto Güricke, a wealthy magistrate of Magdeburg, who amused his leisure by constructing pieces of mechanism, and instituting curious physical inquiries, finding that the belief in the impossibility of a vacuum, with other scholastic tenets, was on the gradual decline, had the boldness to conceive that the forming of a void was a task perhaps within the reach of human ingenuity. Fired with the idea of accomplishing what for ages had been deemed unattainable, he directed all his efforts to compass that end. In his first trials he failed, as might be expected; but, by perseverance, he was enabled to surmount every obstacle. Having filled a wooden cask with water, he attempted to extract this again, by means of a small sucking pump, introduced at the bottom of the cask, and worked vigorously by three stout men; a hissing noise was heard like that of boiling Discovery of the air-pump by Güricke.

Barometer. water, the air entered from above through the interstices of the wood, and the water flowed out. The more effectually to exclude the air, he next took a smaller cask, with a sucker attached to it, and placed it within a larger one, having filled up the space between them with water. On working the pump as before, the water was forced through the pores of the wood into the inner cask, but none was extracted by the action of the piston. Foiled in these attempts with wooden casks, he had recourse to a copper ball, to the under part of which he screwed an inclining sucker; and, with this apparatus, he at last succeeded in extracting the air. He continued the operation, till no further portion of air was perceived to issue from the vent. On opening the cock again, the air rushed into the cavity of the ball with violence; and the same effect took place, with scarcely any diminution of power, after an interval of a day or two. The construction of the machine was afterwards rendered more perfect, by substituting a large inclined metal sucker, with its joints secured by immersion in water.

Such was the origin of that most valuable addition to philosophical apparatus, the air-pump, which long retained its earliest rude and simple form on the Continent. By help of this new and powerful instrument, Gürické was enabled to perform some interesting and very important experiments. One of these, which demonstrates in a very striking way the pressure of the atmosphere, has since been deservedly styled the Magdeburg Experiment. It was performed with two hollow copper hemispheres, closely fitted together, and the air exhausted from their cavity. This singular experiment Gürické had the honour of exhibiting, in the year 1654, before the princes of the empire and the foreign ministers, assembled at the diet of Ratisbon. The force of two teams, each consisting of a dozen of horses, made to pull in opposite directions, was found insufficient to separate the hemispheres. It was now that the burgomaster of Magdeburg heard, for the first time, of Torricelli's great discovery, and the intelligence must have appeared quite delightful to him, who, by a path so different, had yet arrived at a similar conclusion.

After his return from this splendid assembly, Gürické pursued at home various pneumatical researches. He showed the diminished pressure of the atmosphere at an elevation above the surface, by means of a hollow ball fitted with a stop-cock; having carried this to a height, a portion of the contained air rushed out on turning the cock; but when it was brought down again and opened, the same measure of air apparently flowed into its cavity. He actually weighed the air by ascertaining, with the help of a nice balance, the loss which a large bottle sustained on being exhausted, and found that the air is 970 times lighter than water; a very near approximation, if allowance be made for the residuum of air still left in the bottle. He was the first who proposed the *Statical Balance* for measuring the variations of atmospheric density, consisting of a hollow glass ball about a foot in diameter, hermetically sealed, and freely suspended in the air, to indicate by its different buoyancy the changes which take place in the gravity of the external fluid.

Statical balance.

But Gürické took great pleasure in a huge water barometer erected in his house.[1] It consisted of a tube above thirty feet high, rising along the wall, and terminated by a tall and rather wide tube hermetically sealed, containing a toy, of the shape of a man. The whole being filled with water, and set in a basin in the ground, the column of liquid settled to the proper altitude, and left the toy floating on its surface; but all the lower part of the tube being concealed under the wainscoting, the little image, or weather-mannikin, as he was called, made its appearance only when raised up into view in fine weather. This whimsical contrivance, which received the name of *anemoscope*, or *semper vivum*, excited among the populace vast admiration; and the worthy magistrate was in consequence shrewdly suspected by his townsmen of being too familiar with the powers of darkness.

Barometer

Anemoscope.

Before the taste for experimental science was imported from the Continent into England, the great struggle for the security of public rights had called forth the national energy, and its triumphant success had infused among all classes of men a spirit of boldness and enterprise most favourable to the reception of the new philosophy. The parliamentary commissioners, by removing the more violent and bigoted members of the universities, contributed, on the whole, to encourage a more liberal tone of thinking in those opulent seminaries. Near the close of the civil war, and during the vigorous administration of Cromwell, the philosophy by experiment found some proselytes at last in the cloisters of Oxford, where the mass of antiquated opinions had lain so long embalmed and protected by religious awe. A small association was there formed, for combining together the efforts of individuals in the prosecution of such inquiries; and the fruits of this mutual compact were afterwards visible in the composition of various philosophical works. But the Restoration, by which the nation, in a burst of inconsiderate loyalty, surrendered the privileges which it had purchased with torrents of blood, threw the government of the universities again into the hands of men decidedly hostile to the very shadow of improvement. Experimental science withdrew to a more congenial soil, and sought shelter and support in the wider scope of the capital. The college, founded by the munificence of Sir Thomas Gresham, for the benefit of the citizens of London, though now unfortunately sunk in absolute neglect, had the merit of being the first to extend its protection to the pursuits of inductive philosophy. It produced a succession of professors, eminent in mathematical learning, which is so closely allied with experimental research. A more extensive association was accordingly formed in London, which regularly met at the apartments within the Exchange, and was afterwards, at the suggestion of Oldenburg, the resident from the city of Hamburg, and in imitation of the foreign academies, constituted by charter into the Royal Society. Such was the humble beginning of that illustrious body, and such all the countenance it received from a needy and profligate government. The institution, however, proved at first eminently useful, by its influence in directing public opinion, and the shelter it afforded to experimental philosophy against the jealousy and declared hostility of the clerical and scholastic seminaries. The union of rank, or wealth, or talent, though still very limited in its range, bestowed a degree of lustre on the infant society, that was quite necessary for its defence against the attacks of ignorance and the undermining of bigotry.

Introduction of experimenta. science into England.

Royal Society.

One of the most active members of the Royal Society was the honourable Mr Boyle, who having become acquainted with experimental researches in the course of

[1] It deserves perhaps to be mentioned, that the theatre of the natural philosophy class, in the University of Edinburgh, has for several years been furnished with a water barometer, constructed by Mr Adie. It consists of a fine drawn tube of tin, of half an inch bore, rising thirty feet from a copper basin inclosed under the benches of a class below, and cemented at the top to a glass cylinder two inches wide and about six feet high, exposed to view, but terminating in a small basin containing water. Both ends of this compound column are fitted with stop-cocks, which are opened or shut at pleasure by means of concealed wires. By this large apparatus the Torricellian experiment is likewise exhibited in a very striking manner.

Barometer. his travels, devoted, after his return home, his time and his fortune to such calm but engaging pursuits. In this occupation he derived the most essential aid from Dr Hooke, whom he had the discernment to engage as his assistant,—the most skilful mechanician, and one of the best practical philosophers, of the age. The same ingenious person was likewise employed as operator to the society, and undertook to produce at each meeting some new experiments for the instruction and entertainment of the members. One of the favourite subjects was to exhibit the properties of the atmosphere. Hooke, at the instance of Boyle, had given a more convenient form to the air-pump, and had materially improved its construction, especially by the application of oil to the joints and valves. With this improved machine, a more perfect vacuum was procured than Gürické had obtained; and the English philosophers were thus enabled to perform a variety of delicate and interesting experiments, which extended the influence of the original discovery.

In those early meetings, too, of the Royal Society, the suspension of the mercury in the Torricellian tube had still the attraction of novelty. The famous Italian experiment, as it was called, was frequently repeated and varied in the presence of a few of the more assiduous members, who, though delighted with the exhibition, still continued to argue and to doubt concerning the cause of the phenomenon. These doubts acquired new force from a singular experiment which the celebrated Huygens some years afterwards communicated, during a visit he made to London. Having filled a glass tube eighty inches long with mercury, and carefully expelled whatever air was lurking about the sides, he gently inverted it, as usual, in a basin; when the mercury notwithstanding remained still hanging from the top of the tube, and did not subside to the proper height till it was struck with a slight blow. This anomalous fact appeared then extremely puzzling. The experiment, indeed, requires great nicety and address on the part of the operator, and evidently depends on a concurrence of circumstances which have not yet been sufficiently explained. There can, at present, exist no doubt that this extraordinary suspension of the mercury is occasioned by its obstinate adhesion to the inside of the tube, which, in the process of purging the air, becomes probably lined with a very thin film of mercurial oxyd. But Huygens, who had embraced the leading principles of the Cartesian philosophy, was inclined to draw a very different conclusion. He thought that the fact proved the existence of another fluid besides the atmosphere, and one possessed of such extreme subtilty and power, as to be capable of permeating the grosser bodies. In ordinary cases, this fine ethereal substance might be supposed to escape through the pores of the glass, and leave the mercurial column to the pressure merely of the atmosphere. Such was the unfortunate introduction of that ideal being—an æther—into experimental science, which it has continued to infest with mysticism, and to dazzle with a false glare. Similar notions are perpetually renewed by a certain class of superficial inquirers, and have exercised a visible and most pernicious influence in retarding the progress of sound philosophy.

Huygens's experiments.

Cistern barometer. It was soon perceived that the siphon barometer of Torricelli has a disadvantageous form. Both branches of the tube being assumed to be of the same width, the mercury must evidently sink as much in the one as it will rise in the other; so that the variations in the height of the column are thus reduced to half the true quantity. A small basin, or semicircular wooden box, to hold the surplus mercury, was therefore attached to the frame of the instrument; and this construction, with very little change, was adopted, during the course of a century, by the makers of the ordinary barometer. But the syphon barometer itself was afterwards materially improved by having its lower branch blown into a wide bulb for holding the charge of mercury. (See fig. 2, Plate CIV.) This form of the barometer is not quite accurate, owing to the smallness and unequal shape of the round bulb; but being very convenient for carriage, it has grown into general use, at least for the cheaper and more common sort of instruments. Barometer.

As soon as the barometer came to be regarded as a weather-glass, ingenuity was set at work to devise the means of enlarging its scale of variations. Descartes first proposed a simple method for effecting that object, by combining a mercurial with a water barometer; which arrangement, though subject to imperfection, has led to many of the subsequent improvements. (See fig. 4.) He directed two short barometric tubes to be cemented, the one into the bottom, and the other to the neck of a phial; or, still better, that the tubes should be joined, by the flame of a lamp, to the opposite ends of a wide and regular cylinder. The lower tube, and a portion of the cylinder, were then to be filled with mercury, and above it was to be introduced pure water, reaching to the top of the upper tube, and there sealed close. When this compound tube was inverted in a basin of mercury, it is evident that the columns both of mercury and of water would sink, till their joint pressure became just equal to the superincumbent weight of the external atmosphere. But the variation of this weight would afterwards be indicated chiefly by the large motion of the water; since the mercurial column, spreading out above into a broad surface, must, in any case, experience a very slight difference of altitude. Thus, suppose the cylinder to have eight times the diameter of the upper tube, or a section sixty-four times greater, mercury being 13·6 times denser than water: for each inch of increase of altitude which the ordinary mercurial column gains, the top of the water would be raised in the tube 11·4 inches, its own rise being 11·18 inches, and that of the wide mercurial cylinder only ·18 of an inch, yet equal in pressure to 2·4 inches of water. But Descartes, generally satisfied with mere theory and speculation, did not live to see his construction of the barometer carried into effect; and Chanut, the French resident at Stockholm, to whom he had imparted his views, met with such difficulty in the execution of the project, that, after some fruitless attempts, he abandoned it altogether. Barometer of Descartes.

Huygens was more fortunate, and succeeded, by dint of perseverance and skill, in constructing the Cartesian barometer. But he had the mortification to find that, in spite of all the pains he could take, the water, after it was relieved from the pressure of the atmosphere by the sealing up of the tube, constantly discharged a portion of air, which collected at the top, and by its elasticity depressed the compound column below its due altitude. Convinced that this source of imperfection is irremediable, he sought to rectify the construction of the instrument, and produced his *Double Barometer*; a form of combination frequently used, especially when the object is rather to make the variations very sensible than to obtain delicate results. (See fig. 5.) He joined a barometric tube of the usual length, by the flame of a blow-pipe, to two wide cylinders, the one sealed at the top, and the other annexed likewise hermetically to a tall and narrow tube, open at its extremity; he then bent the thicker tube a little above the lower cylinder, and brought the two branches to be parallel. The instrument being thus formed, he filled the first branch with mercury, and introduced above, in the second branch, some liquid of comparative lightness. Alcohol would, in this respect, answer extremely well, if it were not so lia- Huygens's double barometer

Barometer. ble to waste by evaporation. An alkaline lye, or the deliquiate salt of tartar, which also readily admits of being coloured, was therefore, on the whole, preferred.

The principle of this construction is evidently the same as in that of Descartes; but the vacuum lying contiguous to the mercury itself, can have no admixture of disengaged air or of aqueous vapour. Since the cylinders are made very much wider than the bore of the annexed tube, the variation of pressure will be produced almost entirely by the change of altitude which the alkaline liquor undergoes, the mercury suffering only a very minute alteration of ascent or descent. The divisions of the ordinary scale will be about tenfold enlarged, if a section of each cylinder should exceed twenty times that of the tube in which the liquor plays.

Its advantages and defects. A barometer of this construction has decided advantages with respect to the extent of its variations, but still it is not exempt from considerable defects. The moisture on the inner surface of the cylindrical reservoir increases the adhesion of the mercury, and retards its movements. But a much greater source of error proceeds from the influence of heat in extending the volume of liquor contained in that reservoir, and rising into the narrow stem. This instrument, therefore, to a certain extent, blends the indications of the barometer with those of the thermometer, which are essentially different, and can seldom accord.

Hooke's double barometer. About the same period Dr Hooke likewise proposed a double barometer, of a similar construction. He afterwards resumed the subject, and with a view to correct the defect of the former arrangement, he produced, in 1685, an instrument of a more complex form, but very ingeniously conceived. (See fig. 6.) To the upper end of the open stem he joined a third cylinder of the same dimensions as the two former, but tapering away to a fine orifice at the top. The principal tube being filled as usual with mercury, extending to occupy the bottoms of both the connected cylinders, he introduced a liquor immediately over the mercury in the second cylinder, rising partly into the stem; above this, again, he poured another liquor specifically lighter and differently coloured, filling up the rest of the stem, and mounting into the third cylinder. By this artificial and delicate combination, the mercury is left perfectly stationary, and all the movements corresponding to the atmospheric pressure are performed by the counterpoising liquors, and marked by their line of mutual separation. Since the stem or narrow tube remains constantly full, the variation of its pressure must depend on the different proportions of its length occupied by the two fluids. If the weight of external atmosphere should, for instance, increase, the denser liquor will rise, and consequently cause the lighter liquor to contract its column. The action of this compound barometer, being thus produced merely by the difference of the gravity of the two fluids, might, therefore, be augmented indefinitely. Suppose the liquid resting on the mercury to be pure water, and the superincumbent liquid to be olive oil, which is about one twelfth part lighter; the scale would be enlarged no less than 163 times, or an alteration of one tenth in the altitude of the common mercurial column would be marked by a motion through $12 \times 1{\cdot}36$ inches, or 16·3 inches. But such a vast enlargement of the scale is far greater than would ever be desirable in practice. It were better, therefore, to introduce next the mercury some fluid which is denser than water. If oil of sassafras were combined with oil of oranges, the divisions of the scale would be augmented only sixty-eight times, and consequently the whole range might not exceed ten or twelve feet. Those oils, however, would move rather sluggishly, especially in cold weather, and might, from their incessant shiftings, during a lengthened period, become insensibly mixed. On the other hand, fluids of distinct characters are seldom free from chemical action; they expand differently with heat, and by coating with other traces the inside of the tube, they are the more apt to retard the motion of the column. In general, the advantage of any very great augmentation of the scale is counterbalanced, as the fluids then work by irregular starts; and the instrument loses in delicacy whatever it has gained in extent of action. Barometer

Wheel barometer. Another method of augmenting the variations of the barometer was invented by the same fertile genius, which has the advantage of uniting great simplicity with tolerable accuracy. (See fig. 7.) Resuming the siphon barometer, he made a small float of iron or glass to rest on the exterior surface of the mercury, and suspended by a slender thread passed round a small wheel or cylindrical axis that carried an index. Though the varieties of the height of the mercurial column are, in a tube of this form, reduced to half the ordinary measure, yet, from the great length of the index compared with the diameter of its axis, the divisions on the circumference of the circle in which it travels are much amplified. The little machinery being concealed within the frame of the instrument, the index only is brought into view, protected by a circular plate of glass. Thus fitted up, the whole forms rather a handsome piece of furniture. The *Wheel Barometer*, as it is called, has long maintained its reputation among ordinary observers.

Inclined barometer. A very simple method of enlarging the divisions of the barometer is commonly ascribed to Sir Samuel Morcland, the same speculative adventurer who invented, or rather introduced from abroad, the *Speaking Trumpet*. (See fig. 8.) It consisted in merely bending the upper part of the tube into a very oblique position. By this deflexion, however, the scale which depends on the perpendicular altitude cannot be augmented beyond three or four times without incurring evident risk of inaccuracy. The instrument is called the *Inclined* or *Diagonal Barometer*. The form has been sometimes varied by the fancy of artists, who, repeating the inclination of the tube, have occasionally given the upper part a zig-zag appearance.

Square barometer. The most ingenious barometer, filled with mercury only, and yet admitting a scale of any extent, was invented by Cassini and by John Bernoulli, who first gave the description of it in 1710. (See fig. 9.) A wide cylinder is annexed to the top of the main tube, at the bottom of which there is joined at the right angles another long and narrow tube. The mercury, in ascending or descending within the wide cylinder, must, therefore, run along this horizontal tube. If that cylinder have a diameter only four times greater than the bore of the tube, the scale of variation will be augmented sixteen times. This instrument is, from its shape, called the *Square Barometer*. It is not found in practice to answer so well as the theory might lead us to suppose. The mercury creeps along the horizontal tube with difficulty, and by desultory advances; and these irregularities increase when, from its motion and exposure, it becomes covered with dust and partial oxidation.

Conical barometer. The simplest of all the barometers with an enlarged scale, and at the same time one of the most ingenious, is the *Conical* or *Pendant Barometer*, invented and described in 1695 by Amontons, a French philosopher, who, being afflicted with total deafness in consequence of a fever in his infancy, had devoted himself to mechanical contrivances. (See fig. 3, Plate CIV.) This instrument consists merely of a tube, four feet or more in length, with a bore narrower than ordinary, and tapering regularly to the top. The width at the bottom must hardly exceed three twentieth parts of an inch, while near the

Barometer. top it may be contracted to about one tenth. A column of about thirty-one inches of mercury being introduced, the tube is gently inverted and held perpendicular; the cohesion of such a narrow column is sufficient to prevent it from dividing and admitting air unless it be shaken; but, overpowering the atmospheric pressure, it descends till it has contracted into the equiponderant altitude, by passing into a wider part of the tube. To obtain equal divisions on the scale, it is necessary that the tube should have a uniform taper. The most accurate construction of a barometer of this kind is, therefore, attained by joining together two tubes that have even but unequal bores, the longer and narrower one being uppermost. If the width of the upper tube were supposed to be to that of the under one as two to three, the scale would be enlarged three times, since, by descending three inches from the top, and consequently two at the bottom, the column would suffer a contraction of one inch in height.

This species of barometer is thus recommended by its simplicity and its ample range. But the bore of the tube being indispensably narrow, the mercury moves with difficulty, and resists the impression of minute changes of external action. When the conical-shaped tube is retained, the instrument is liable to some inaccuracy from the influence of the cohesion of the mercury, which varies with the diameter of the column in different parts of the tube.

Amontons likewise proposed another form of barometer, in which the mercurial column is subdivided among several short connected branches. (See fig. 10.) Suppose the instrument were to have only the third part of the usual height, the first, third, and fifth branches, enlarged above and below into very short cylinders, are filled with mercury; and the second, fourth, and sixth branches, which may have their bores narrower, are occupied with some light fluid, or simply with air. If the external pressure should suffer any diminution, the three mercurial columns which produce the counterpoise will each descend and push up the last fluid of the series by their combined effects. It is evident that, by multiplying those branches, the barometer will have its altitude proportionally reduced. But this construction, though specious in theory, is found to have no practical advantages. The instrument is, from its complication, very difficult to construct; its motions are sluggish, owing to the multiplicity of tubes and the conjunction of fluids, and they are subject to derangements from the variable influence of temperature. It has therefore been generally abandoned.

Sectoral. Barometer. These different forms of the instrument have been variously modified, and often brought forward with claims of novelty. We may notice, however, the *Sectoral Barometer* proposed by Magellan, in which the mercury is always made to rise to the same high point of the tube, by drawing this less or more aside from the vertical position. The arc thus described will indicate the deviation from the perpendicular, and consequently the actual descent of the mercury. But the difference between the vertical and the oblique line is not measured by the inclination merely, it is proportioned to the versed sine of this angle, or nearly to the square of the arc. The advantage of this mode of observing is, therefore, best perceived in small variations of the mercurial column. In the hands of a skilful observer, the best and most accurate barometer, after all, is that of the original construction, with a tube rather wide, and a broad cistern. To apply minute divisions is decidedly preferable to any enlargement of the scale. The measuring of such divisions has been since rendered extremely easy by the adaptation of the differential scale; a most valuable contrivance, proposed by Vernier early in the seventeenth century, but strangely neglected long afterwards. This delicate appendage being once adopted, it became the more desirable to improve the sensibility and regulate the correctness of the indications of the barometer. Barometer.

Effect of moisture within the barometric tube. The first object was carefully to cleanse the mercury, and to expel any portions of air or moisture adhering to the inside of the tube. The influence of aqueous vapour in depressing the mercurial column had been observed by Huygens; but other more evaporable fluids were afterwards found to occasion, by their presence, a still greater derangement. Homberg having, about the year 1705, washed a tube with alcohol to remove the impurities from its internal surface, remarked that the mercury introduced into it stood an inch and half lower than usual, a depression which this ingenious chemist was disposed to attribute to the elasticity of the spiritous exhalations collected above the mercurial column; though other academicians, and Amontons among the rest, misled by their Cartesian prejudices, sought to ascribe the effect to the different sized pores of the glass. These anomalies were removed by heating or rather boiling the mercury in the tube till it was completely purged of air and moisture, and brought into close contact with the inside of the tube But a new fact occurred which long puzzled the mechanical philosophers. The tube of a barometer, which had been filled with more than usual care, was observed to exhibit a luminous appearance when moved or slightly agitated in the dark. This curious phenomenon gave occasion to multiplied and prolonged controversies; it was attributed to the subtile matter of Descartes, or ascribed to a native phosphorescence, or a latent fire inherent in the mercury. Our countryman Hauksbee, in the year 1708, gave the first rational explanation of the fact, by referring it to electricity, which he had just begun to cultivate as a distinct science. It resembles exactly, indeed, the experiment of the exhausted flask, in which an electrical current flashes with a diffuse lambent flame, like the *aurora borealis* or the *northern streamers*. The friction of the mercury against the inside of the tube excites electricity, while the vacuity, or rather the very attenuated vapour in which the supposed fluid plays, facilitates its expansion. When the vacuum is rendered very perfect by the careful and accurate boiling of the mercury, the lambent flashing ceases for want of a fine medium to conduct and disperse the electrical influence. Luminous barometer.

Effects of the width of the tube. The next point to which experimenters were led to direct their attention, was the effect of the width of the tube on the altitude of the mercurial column. Plantade, a lawyer of Montpellier, appears to have been one of the first who remarked that the mercury stands always lower in narrow tubes. This fact he communicated about the year 1730 to Cassini, who was then occupied in the south of France with carrying on the great trigonometrical survey. But the discrepancies observed by Plantade, being unfortunately confounded with other collateral circumstances, were for a time overlooked. In tubes having a narrow bore, the depression of the mercury, however, is very considerable, as may be readily perceived in a small glass syphon, of which the one branch is about half an inch in diameter, and that of the other branch less than the tenth of an inch. Thus, if the narrow tube had a width of only the thirteenth part of an inch, the depression of the mercury would amount to half an inch, which is about the third part of the elevation to which water in similar circumstances would be raised by capillary action. This effect has not been sufficiently examined, but it appears to result from the attraction of the particles of the mercury to each other exceeding their attraction to the surface of the glass. Mercury, in contact with glass, therefore, tends to a spherical form, and always assumes a convex

Barometer. surface within a clean tube. Water and other liquids, again, manifest an opposite character, the mutual attraction of their particles being less than their adhesion to glass. Accordingly, they spread along a vitreous surface, instead of collecting into drops; and in narrow tubes they mount above the level, and invariably have a concave termination. If the bore be so small as to be reckoned capillary, the depression of mercury is, like the elevation of water, inversely as the diameter; but when the bore has a considerable width, the quantity of depression, depending on the curvature of the surface of the mercury, diminishes proportionally faster, and follows nearly the inverse duplicate ratio of the diameter. But on the subject of capillary action we refer our readers with the utmost confidence to a valuable paper communicated to the Royal Society of London, by Mr Ivory, late of the Military College at Sandhurst, one of the most original and profound mathematicians that our island has had the honour to produce.

Pure mercury has always a convex surface.

The influence of the predominating attraction of the particles of mercury to themselves, above their adhesion to the sides of a glass tube, has not been considered with so much attention as it demands. Nothing is more common than to remark that the mercury in the barometer is in the act of rising if it show a convex surface, but about to fall if it should appear concave. Now, the top of the mercurial column must always remain convex if the barometer be properly constructed, the tube perfectly clean, and the mercury purged of all impurities. But if the inside of the tube be anywise soiled, whether covered with humidity or stained with mercurial oxyd, the metallic fluid will adhere so obstinately to the glass as to lose its convexity, and to subside into a flat surface, or even sink into a concavity, like water and other liquids. Hence the danger of boiling the mercury too long in the tube, as it becomes partially oxydated; and the thin crust so formed not only suspends the column higher, but obstructs the freedom of its motion. The same effect is produced by greasing the inside of the tube. Some respectable authors, from not attending to these facts, have hastily inferred that the convex appearance which mercury assumes in the barometer was merely accidental, and consequently removed by a more complete boiling and purification.

Quantity of depression in different tubes.

In the case of tubes having wide bores, the depression of the mercurial column may, without any sensible error, be disregarded. According to the accurate experiments made by Lord Charles Cavendish, and published by his son the celebrated Mr Cavendish, the quantity of depression is only the 200th part of an inch in a tube of 6-10ths of an inch in diameter, the 28th part of an inch in a tube of 3-10ths diameter, and the 15th part of an inch in a tube of 2-10ths diameter. Wide tubes ought, therefore, to be preferred in the construction of barometers, both on account of the facility with which the mercury moves in them, and the smallness of its depression. The only circumstance to overbalance these advantages would be the necessity and inconvenience of having a very large cistern. A quarter of an inch may be reckoned a good width of tube, and the corresponding depression is only the twentieth part of an inch.

In the siphon barometer, if both branches have the same diameter, the action is exerted on opposite sides, and therefore the effect of depression becomes entirely lost. For accurate purposes, this original form of the instrument has been resumed, and the inconvenience arising from the large variation of the lower lever entirely obviated by an ingenious contrivance introduced above fifty years ago. This consists in the application of a leathern bag, instead of a wooden or ivory cistern, to hold the surplus mercury. Besides the barometric tube, there is placed adjacent to it another short one of the same width, communicating with the mercury contained in the bag, which being pressed by turning a screw below, is at each observation brought exactly to the same mark. The external atmosphere readily acts through the substance of the leather; but the mercury, from the powerful cohesion of its own particles, cannot be squeezed through the pores of that casing without violent compression. The addition of a bag within a cylindrical box, omitting the lower tube, likewise renders the barometer easily portable; since, for safe carriage, the mercury can be screwed up tight, to fill the whole cavity of its tube, but, on turning the screw again, the column will subside and rest on a broad base.

Application of a leathern bag.

Barometer.

The last object which required nice observation, was to estimate the effect of heat in dilating the mercury, and consequently increasing the altitude of the equiponderant column. This correction could not be made with any sort of accuracy previous to the application of the thermometer, which, though invented half a century earlier than the barometer, was yet more than another half-century in arriving at perfection. Hero, a mechanical philosopher, who flourished at Alexandria about 130 years before Christ, has described in his *Spiritalia* a sort of huge weather-glass, in which water was made to rise and fall by the vicissitudes of day and night, or rather the changes of heat and cold. This machine had for ages been overlooked, or merely considered in the light of a curious contrivance. But Sanctorio, the inventor of the famous statical balance, a very learned and ingenious Italian physician, who was long professor of medicine in the university of Padua, and had laboured to improve his art by the application of experimental science, reduced the hydraulic machine of Hero into a more compendious form, and thus constructed, about the close of the sixteenth century, the instrument since known by the name of the *air thermometer*, which he employed with obvious advantage to examine the heat of the human body in fevers. Some years afterwards a similar instrument was contrived, perhaps without any communication, by Drebbel, a very clever and scheming Dutch artist, who visited London in the reign of James I., and imported the knowledge of that instrument into England.

Effect of heat on the barometer.

Invention of the thermometer.

But this air thermometer was evidently of the same nature with what has been since called the *manometer*; it could measure only the dilatation or augmented elasticity of the air confined within its bulb, whether occasioned by heat or the diminution of external pressure. It was therefore considered merely as a weather-glass, indicating the state of the atmosphere; nor could its blended impressions, which might separately affect both the thermometer and barometer, be then distinguished. Had it been more closely studied, it must have led, by another path, to the discovery of the latter. But those irregularities to which the air thermometer was hence subject appear to have created such doubts respecting the accuracy of the instrument, as occasioned its being neglected long afterwards.

Florence glass.

The same country, however, which had given birth to the thermometer, began its improvement. After the principle of the barometer was established, the members of the Academy del Cimento, founded at Florence in 1657, and supplied with liberal funds by the grand duke of Tuscany, had, among other interesting physical researches, resumed the application of the thermometer; and, instead of air, they substituted alcohol or spirit of wine, another very expansible fluid not affected by atmospheric pressure, while they attached to the tube a scale graduated on a regular plan, though directed by no very precise measures. The instrument so constructed, but somewhat varied in its form, being copied by Italian ar-

Barometer.

tists, was dispersed over Europe under the name of the *Florence Glass*. From its careless execution, however, in the hands of itinerant venders, this thermometer, or rather thermoscope, appears never to have obtained an established reputation.

Attempts to obtain a standard.

The great object proposed was to bring thermometers to an exact correspondence. It was expedient, therefore, not only to select a proper fluid, but to adopt a uniform and consistent scale. Alcohol, linseed oil, and mercury, had been successively tried. The graduation was at first derived from the temperature of cellars and deep caves, which, indicating the natural heat of the globe, had long been considered invariable; but more enlarged experience discovered the inaccuracy of that supposition, and showed the mean temperature to be materially modified by the latitude of the place, and its elevation above the level of the sea. Congelation, or rather the inverted process, the thawing of ice, or the melting of snow, was then found to remain fixed; a most important fact, which had been first noticed by Güricke, but overlooked till a considerable time afterwards. A stationary point was hence obtained, from which to commence the thermometric scale. But different modes were pursued for determining the divisions.

Amontons.

Amontons, reverting to the air thermometer in spite of its acknowledged defects, found that the elasticity of air compressed in the bulb, and able at the temperature of melting snow to support a column of mercury fifty-four inches high, was capable of raising this to seventy-eight inches at the heat of boiling water; and he seemed contented with framing a rude standard, by merely dividing the intermediate space into inches and half-inches.

Newton.

But about the same, or nearly at the beginning of the eighteenth century, Newton himself cast a keen though rapid glance on the subject of heat, and proposed a thermometer of a much simpler and more elegant construction. Having adopted linseed oil as a fixed and uniform substance, capable of great dilatation, he discovered by experiment, that dividing the capacity of the bulb into ten thousand equal parts, the liquid expanded 256 parts from melting snow to blood-heat, and 725 parts to that of boiling water. These numbers, however, being inconveniently large, he reduced them somewhat more than twenty times, adopting 12 and 34 as the proportional divisions on his scale. But oil, being so viscid a substance, was found to trail and collect on the inside of the tube; and this thermometer, though constructed on a right principle, never came into general use.

Roemer.

Roemer, the Danish astronomer who made the fine discovery of the progressive motion of light, was the first who proposed mercury as the fittest fluid for thermometers; and Halley and Amontons remarked about the same time, that it expands uniformly with heat, and remains nearly stationary at the point of boiling water. On this

Delisle's thermometer.

principle, Delisle of St Petersburg constructed, in 1733, a mercurial thermometer with a descending scale, the distance from freezing to boiling water occupying 153, or, in round numbers, 150 divisions, of which the bulb itself contains 10,000. A more ingenious method, but perhaps too refined, for graduating thermometers, was proposed

Renaldini.

by Renaldini, a distinguished Italian mathematician, in 1694. It consisted in adopting the scale, in the successive temperatures produced by mixtures, in the different proportions of twelve parts of water at the moment of thawing and of ebullition. This suggestion led to a very important inference, since it proved that mercury expands uniformly with equal additions of heat, while alcohol swells constantly in a rising progression. But the capital

Fahrenheit's thermometer.

improvement of the thermometer was effected by the skill and perseverance of Fahrenheit, whose name has remained justly attached to the instrument. This ingenious person, originally a merchant at Dantzic, who had the misfortune to fail in business, was induced, by his taste for mechanics and chemistry, to have recourse to the manufacture of thermometers, as the means of gaining a slender livelihood. But not meeting with sufficient encouragement at home, he removed, about the year 1720, to Holland, the great emporium of the arts, and fixed his future residence at Amsterdam. He now preferred mercury to alcohol for filling his thermometers; and, adopting the division of the bulb into 10,000 parts, he reckoned sixty-four of them as the expansion between freezing and blood-heat, and thirty-two as the contraction from the same point to what he considered as extreme cold, or that produced by the mixture of one part of salt with three parts of snow. These numbers were extremely convenient, being found by a repeated bisection. With respect to the heat of boiling water, Fahrenheit discovered the important fact, that it varies with the state of atmospheric pressure. Taking the mean, however, he reckoned 180 degrees from freezing to ebullition, and therefore marked this point at 212 on his scale. The thermometer owes its improvement to Celsius, professor at Upsal, who in 1742 placed the commencement of the scale at congelation, and divided the interval thence to boiling water into an hundred degrees, extending such a portion downwards as might be wanted. This centesimal thermometer is exactly the same as what the French have since called the *centigrade*, which, from its fitness and simplicity, deserves to be universally adopted.

The Celsian or centigrade thermometer.

The thermometer having been thus carried by successive steps to perfection, it was found by delicate experiments, that, between the points of boiling and freezing, the expansion of mercury amounts to the fifty-fourth part of its bulk, or that it acquires, for each degree of heat, an increase of volume amounting to the 5412th part on the centesimal scale, or the 9742d part on the scale of Fahrenheit. A correction, therefore, on the height of the mercurial column in the barometer becomes necessary according to the changes of temperature which it undergoes In this climate, the extreme variation arising from that cause will seldom exceed two tenths of an inch. But if the barometer be suspended in a room kept at an agreeable temperature, the error occasioned by the expansion of the mercury may, in ordinary cases, be disregarded, since it will scarcely amount to the twentieth part of an inch.

Correction of the barometer as affected by heat.

Since the barometer marks the condition of the distant atmosphere, and intimates those internal alterations which are generally connected with the change of the weather, it is particularly valuable at sea, by forewarning the mariner of the approach of a storm. But an instrument of the ordinary construction would not answer this purpose, the agitation of a vessel on a tempestuous ocean being such as would not only throw the ponderous mercurial column into violent oscillation, but communicate those sudden shocks which must infallibly break the tube. Various attempts have accordingly been made to obtain a *marine barometer* exempt from risk, and yet sufficiently sensible to the variations of the atmosphere. The conical or pendant barometer being, from the narrowness of its bore, rather sluggish, was first recommended for that purpose, though never adopted into practice. About the beginning of the eighteenth century, Dr Hooke and Amontons severally proposed to employ for a barometer on board ship, the manometer or air thermometer. To obviate the derangement arising from the influence of heat, there was to be placed beside it a spirit-of-wine thermometer, with a ball so large as to give expansions equal to those of the portion of air confined within the bulb. The difference between the two adjacent columns of liquid would there-

Marine barometer.

Barometer. fore measure the variation of external pressure. But to procure such a nice adaptation would prove so extremely difficult in practice, that most probably this instrument was seldom or never actually constructed. Besides, the liquid column of the manometer, though light and narrow, would yet be much shaken by the rolling and pitching at sea. Notwithstanding these weighty objections, however, this compound manometer was tried in England, mercury being employed as the fluid both of expansion and pressure, and various adjustments applied by means of a complex machinery.

Blondeau's marine barometer. An ingenious and very substantial kind of marine barometer was, above twenty years ago, recommended by Blondeau, one of the professors of the naval academy at Brest. (See fig. 11, Plate CIV.) It consisted of an iron tube, bent below into a siphon, and filled carefully with mercury, which carried a float. For this purpose, a musket-barrel, about three feet long, was chosen, having a very smooth and even bore, and an iron breech closely welded to it, instead of being soldered with brass, which might become corroded by the action of the mercury. The lower end of the tube had a collar of leather, to which was screwed a piece of iron, perforated through its whole length, and bent into an arch, having screwed likewise, with a collar of leather at its other extremity, a vertical cylinder of iron, four inches high, and of the same bore exactly as the tube. The contracted aperture at the end of the tube, not being exactly in the middle, was not always opposite that of the arch; and, therefore, by turning it occasionally aside, the communication could be contracted at pleasure, or even obstructed entirely. The cylindrical appendix was tapered at the top to a narrow orifice, through which an iron wire, attached to a small ivory float, had been introduced. To prepare this instrument for action, the mercury was first boiled in the tube; then the arch, filled with hot mercury, was screwed to the end, the cock opened, and the surplus mercury allowed to flow over; next the vertical piece, with its float, was screwed on, and a little mercury added, to give it due play. The origin of the scale was to be determined from the comparison with another good barometer of the ordinary construction; but, owing to the equality of the bores of the opposite tubes, the divisions were only half the usual size, or the inches were exhibited by half-inches.

This species of barometer is certainly free from all sort of risk, while the facility which, by means of turning the arch, it affords in checking the ascent and descent of the mercury, prevents in a great measure the oscillations of that fluid. If the instrument were properly suspended, therefore, its indications would be tolerably steady and regular. The chief objection to it consists in the diminutive range of its scale.

In every marine barometer, the main object is to give steadiness to the mercurial column, by retarding its motion in the tube; in short, to imitate the equalizing effect of the fly in mechanics. One form of construction was, instead of the cistern below, to annex a spiral tube composed of a number of horizontal convolutions. Passemant, an ingenious Parisian artist, about the year 1758 improved on this idea. He twisted the barometer tube near the middle, at least twice round, and joined to its upper end a wide cylinder. But, more effectually to prevent all irregular oscillations, he took a tube with a very narrow or capillary bore, and contracted it below, while he annexed a wide cylindrical piece at its other extremity. The only thing wanted now to the perfection of this instrument, was to devise a mode of suspending it that should soften the jerks, and allow it generally to maintain a vertical position. Our English artists have, by repeated trials, at last succeeded in surmounting all the difficulties. The marine barometer, manufactured by Mr Cary of London (see fig. 12, Plate CIV.), is one of the most approved kind. It consists of a capillary tube, about twenty-seven inches long, with a bore scarcely exceeding the thirtieth part of an inch, but terminated by a cylinder four or five inches high, and nearly three tenths of an inch in diameter. It is suspended by a spring and jimbols, near the top, at a certain point, which in each case is discovered by actual trial. By making the suspension lower, it is found that the agitation of the barometer will cause the mercury to rise a little; while, by placing the suspension higher, the mercurial column suffers always some depression. The reason of this curious observation is not well explained. It probably results from the different centrifugal tendencies communicated to the opposite portions of the columns. The swinging of the instrument would evidently augment the pressure of the upper portion of the column, while it diminished that of the under portion. But this lower portion being longer than the other, its tendency to descend would be proportionally so much greater. About the point of suspension, however, the opposite effects of the centrifugal tendencies are balanced, since the superior force being employed to set in motion a narrower column, the reflux and efflux of the mercury in the upper cylinder must be preserved nearly equal. Barometer.

Marine barometers, thus improved, are now very generally used, and with great benefit to the public service, on board ships of war and Indiamen. To facilitate the keeping of a register of barometrical observations, the meritorious and indefatigable Mr Horsburgh, hydrographer to the East India Company, published a set of engraved ruled sheets, adapted for the convenience of navigators. In these plates the height of the mercury, from twenty-seven to thirty-one inches, is represented in inches and tenth parts by horizontal lines, while each successive day has a space apportioned to it by vertical bars. The state of the barometer at every observation is marked with a dot, and these dots being afterwards connected together, exhibit an irregular waved line, stretching across the sheet, and indicating the series of the changes of the weather. At the lowest points, from which the curve again returns, a gale generally follows. From the observations made off the Cape of Good Hope during the month of May 1815, by an ingenious and active officer, Captain Basil Hall, then of his majesty's sloop Victor, it appears that whenever the mercury fell to 29·60 inches, a storm ensued; the column always rose when the gale abated, and when it reached near thirty inches, the weather became fair. Those gales often came on suddenly, without any visible change in the aspect of the sky, but the marine barometer never failed to give warning of their approach. Horsburgh's plates.

A very convenient substitute for the marine barometer is the *sympiezometer* constructed by Mr Adie, optician in Edinburgh. It is merely an improved *manometer*, partly filled with a fixed oil, and indicating the conjoined effect of heat and atmospheric pressure on the inclosed air; but the influence of temperature is corrected by means of a sliding scale, regulated by an attached mercurial thermometer. The sympiezometer occupies little room, is easily rectified, and comparatively cheap.

Difficulty in explaining the variations of the barometer. To explain the cause of the variations of the barometer, has long perplexed philosophers. Many hypotheses have at different times been advanced on the subject; but it would be a mere waste of time to make any detailed recital of such crude and unsatisfactory attempts. The various and often imaginary effects of vapours, of heat, and of winds, have been employed in framing an explication of the changes of the atmosphere. The fact, that the mer-

Barometer. curial column generally falls before rain, seemed at complete variance with the intimation of the senses, a notion having become universally prevalent, that the air is heavier when the sky appears lowering and overcast; another proof, were it wanted, how fallacious are all current opinions in matters of science.

Leibnitz, fancying he had discovered a new principle in hydrostatics, endeavoured, by a sort of metaphysical argument, to demonstrate that, though a body adds its own weight to the pressure of a fluid in which it is suspended, yet it will cease to be ponderous during the act of falling. This alleged principle will not, in the actual state of science, be thought to require any serious refutation; nor, were it even admitted, would it be found at all adequate to the explication of the phenomenon, since the weight of moisture precipitated from the whole body of atmosphere could never, by the absence of its pressure, occasion a diminution of the tenth part of an inch in the altitude of the mercurial column.

Dr Halley and Mairan sought to account for the depression of the barometer before a storm, by the withdrawing of the vertical pressure of the atmosphere, when borne swiftly along the surface of the globe by a horizontal motion. This hypothesis at first sight appears very plausible, and might seem further confirmed by a noted experiment which most authors have admitted without due examination. Hauksbee's experiment. Hauksbee, a skilful and ingenious experimental philosopher, about the year 1704 placed two barometers, about three feet asunder, with their naked cisterns in two close square wooden boxes, connected by a horizontal brass pipe; one of these boxes had, inserted at right angles, an open pipe on the one side, and a second pipe, terminating in a screw, on the other side; to this end he adapted a strong globular receiver of about a foot in diameter, which had been charged, by injection from a syringe, with three or four atmospheres; then suddenly opening the stop-cock, and giving vent for the escape of the air through the box and over the surface of the included cistern, the mercury sunk equally more than two inches in both the barometers.

This elegant experiment might be deemed entirely conclusive, if a minute circumstance, on which the success really depends, had not unfortunately been overlooked. Its fallacy. It will be perceived from the inspection of the figure which Hauksbee has given, that the exit pipe of the box was considerably wider than the pipe which conveyed into it the stream of air. This fluid, escaping from compression, would therefore be carried by its elasticity as much beyond the state of equilibrium; while the width of the orifice, by facilitating its emission, would allow the portion occupying the box and the connected reservoir to preserve its acquired expansion. If the pipe of discharge from the box had been much narrower than the other, an opposite effect must have taken place; for the air accumulated over the cistern, not finding a ready vent, would remain in a state of condensation. This curious fact is another of the many instances which might be cited to show the great delicacy and circumspection required in performing philosophical experiments.

Similar results, however, can be exhibited by a very simple apparatus. Let a small box, or rather a glass ball, have a short narrow tube inserted in the one side, and another wide tube opposite to this, with a cross slider of brass, for contracting the orifice at pleasure; and, to the under part of the ball, join a long perpendicular tube, bent back like a syphon to more than half its height, and containing a double column of water. Now, blow through the narrow tube into the cavity of the ball, while the orifice of emission is quite opened, and the liquid will rise several inches in the long stem; but, still continuing the blast, let the orifice be gradually contracted, and the column will first descend to its ordinary level, and then sink considerably below it. Barometer.

The fall and rise of the mercury in the barometer must evidently be occasioned by some corresponding reduction or accumulation of the atmosphere at the place of observation. Whatever augments the elasticity of the air will cause part of the incumbent fluid to evade and leave for the time a diminished vertical pressure. The efflux of wind might also produce a temporary reduction of the atmospheric column. But the real difficulty consists in explaining why the variations of the barometer should be greater in the high latitudes than between the tropics, and why they so much exceed in all cases the quantities which calculation might assign. Causes of the variation of the barometer

The influence of heat will account for the semi-diurnal variations of the barometer which are observed, especially within the torrid regions. From ten o'clock in the morning till four in the afternoon, the mercury generally falls; but, after that hour, it rises again, till ten o'clock at night, when it drops till four in the morning, and then mounts till ten o'clock in the forenoon. These regular changes, which amount to about the five hundredth part of the whole atmospheric pressure, depend on the prevalence of the alternating land and sea breezes, occasioned by the diversified action of the sun's rays upon the earth and water. The accumulation of air is greatest at four o'clock in the morning and evening, and the mercury then attains its highest point; but it sinks lowest at ten o'clock in the morning and evening, when the incumbent mass has been the most reduced.

A similar reason will explain the effects of the northerly and easterly winds, in elevating the mercury of the barometer in our climate. A chill air, with enfeebled elasticity, is thus accumulated and exerts a predominant pressure.

The augmented elasticity communicated to the air by the action of heat or the presence of humidity, and the reduction of the incumbent mass by the efflux of winds, have each their distinct influence in disturbing the equilibrium of the atmospheric ocean. But the effects, particularly in the high latitudes, much surpass the regular operation of those causes. The only mode, perhaps, of removing the difficulty, is to take into consideration the comparative slowness with which any force is propagated through the vast body of atmosphere. An inequality may continue to accumulate in one spot, before the counterbalancing influence of the distant portions of the aërial fluid can arrive to modify the result. In the higher latitudes, the narrow circle of air may be considered as, in some measure, insulated from the expanded ocean of atmosphere, and hence, perhaps, the variations of the barometer are concentrated there, and swelled beyond the due proportion. See the articles CLIMATE and METEOROLOGY. (J.L.)

SUPPLEMENT.

Aneroid Barometer. A very ingenious instrument for indicating atmospheric pressure is the invention of M. Vidi of France, which is called the *Aneroid Barometer* (from ἀνέρομαι, I inquire). The appearance and construction will be best understood from the annexed diagrams.

The action of the aneroid depends on the effect produced by the pressure of the atmosphere on a circular metallic chamber exhausted of air and hermetically sealed; thus the chamber is a substitute for the Torricellian tube, and the vacuum for the column of mercury.

Supplement.

The mechanical arrangements of the instrument will be understood by reference to the woodcuts.

Fig. 1.

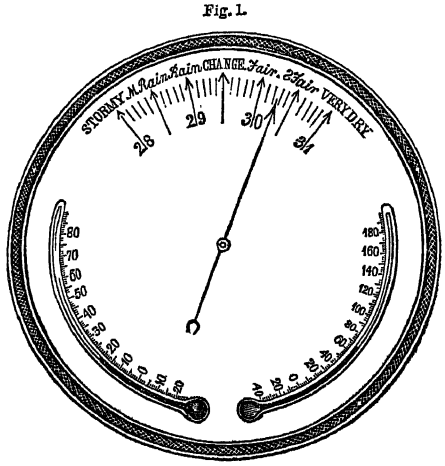

Figure 1 represents the external appearance of the instrument. It is four inches and three-quarters in diameter across the face, and one inch and three-quarters in thickness. The pressure of the atmosphere is indicated by a hand pointing to a scale which is graduated to forty divisions to the inch; one or two thermometers are fixed on the face, as shown in the drawing, but these are not essential.

Fig. 2.

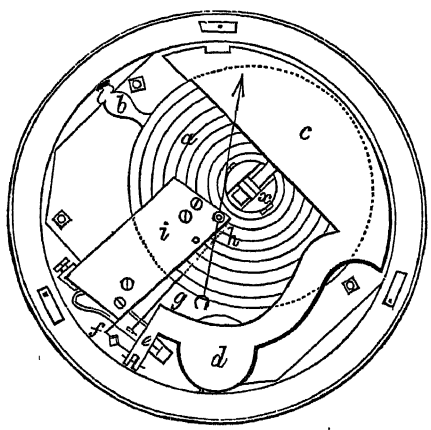

Figure 2 represents the internal construction, as seen when the face is removed, but with the hand still attached. *a* is a flat circular metallic box, about two inches and three-quarters in diameter, and a quarter of an inch in depth, having its upper and under surfaces corrugated in concentric circles. This box or chamber being exhausted of air, through the short tube *b*, which is subsequently made air-tight by soldering, constitutes a spring, which is affected by every variation of pressure in the external atmosphere, the corrugations on its surface increasing its elasticity. At the centre of the upper surface of the exhausted chamber there is a solid cylindrical projection *x*, about half an inch high, to the top of which the principal lever, *c*, *d*, *e*, is attached, as shown in the drawing. This lever rests partly on a spiral spring at *d*; it is also supported by two vertical pins, with perfect freedom of motion. The end *e* of the large or principal lever is attached to a second or small lever *f*, from which a chain *g* extends to *h*, where it works on a drum attached to the arbor or axis of the hand, connected with a hair spring at *h*, changing the motion from vertical to horizontal, and regulating the hand, the attachments of which are made to the metallic plate *i*. The motion originates in the corrugated elastic box *a*, the surface of which is depressed or elevated as the weight of the atmosphere is increased or diminished, and this motion is communicated through the levers to the axis of the hand at *h*. The spiral spring on which the lever rests at *d* is intended to compensate for the effects of alterations of temperature. The actual movement at the centre of the exhausted box, from whence the indications emanate, is very slight, but by the action of the levers this is multiplied 657 times at the point of the hand, so that a movement of the twenty-second part of the tenth of an inch in the box carries the point of the hand through three inches on the dial.

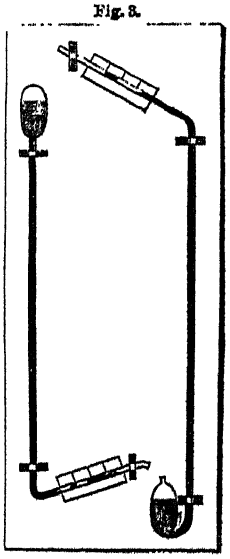
Supplement.

The effect of this combination is to multiply the smallest degrees of atmospheric pressure, so as to render them sensible on the index.



The aneroid is a very delicate instrument, and seems to answer well at moderate elevations above the sea.

Metallic Barometer. M. Bourdon constructed in 1850 a modification of the aneroid, and, like it, a very portable instrument, in which the movement is produced by the inequalities of atmospheric pressure on the convex and concave sides of a thin box in the form of a segment of a circle. The idea is ingenious. It is very similar to a contrivance of Messrs Bryson of Edinburgh in 1849, which diminished the instrument to the size of a small snuff-box. Both appear to be original, but are perhaps inferior to the instrument of Vidi.

Register Barometers. Barometers have been invented which indicate their own extremes of altitude during the absence of the meteorologist. These instruments render his task less irksome; and if generally adopted, would increase our knowledge of atmospheric phenomena.

Dr Traill exhibited to the meeting of German philosophers at Hamburg in 1830, a register-instrument which he had constructed for showing the maxima and minima of barometric pressure during the absence of the observer. It is cheap and simple in construction, and consists of two diagonal barometers, one of which is inverted, and resembles in principle the rectangular barometer. Both are attached to the same frame. Before bending and filling the upright one, and after filling the inverted barometer, a piece of smooth steel wire is introduced into each, to serve as indices to the instrument.

Fig. 3.

When the upright barometer rises, the mercurial column pushes before it the index, which remains there by its own gravity on the sinking of the mercury; so that its extremity next the mercury will indicate the extreme rise of the barometer. When the mercurial column descends in the inverted instrument, which has a small aperture to admit atmospheric pressure at its lower extremity, that index is pushed before it, and its end nearest the mercury will indicate the extreme of the barometric depression, should the increased atmospheric pressure cause that end of the column to recede.

In the first instrument of this kind which Dr Traill constructed the inverted one was the common rectangular barometer; but he conceived that it would be preferable to give the same inclination to the angles of each tube, that the gravitation of both indices might be equal, as represented in the woodcut.

To adjust the instrument for observation, the indices are

Supplement.

drawn into contact with the end of each mercurial column by a small magnet. One of the instruments was used for several years without requiring any fresh adjustment. It is not, however, very portable.

A thermometer should be attached to the frame, to indicate the temperature of the instrument, for the same reason as in other barometers. If the cisterns be of considerable size in proportion to the bore of the tubes, we may for common purposes neglect the adjustment for inequalities in the level of the mercury in the cisterns; to which, indeed, it would not be easy to adapt an accurate indicator.

The general appearance of the instrument will be seen in the woodcut; and the construction, it is hoped, will be understood from this short description. This instrument was first published in a German journal, Oken's *Isis;* and again described in the article PHYSICAL GEOGRAPHY, in the seventh edition of this work.

Keith's Siphon Barometer. The late Alexander Keith, Esq. of Ravelston, invented one of the first of such instruments, which was described in the 4th volume of the *Transactions of the Royal Society of Edinburgh.* It is a siphon barometer, in the shorter limb of which an ivory float rests on the surface of the mercury, and carries a wire bent at the top at right angles. This bended extremity is placed between two lists of oiled silk, which it moves up and down as the float rises and falls with the mercury, on a wire stretched along the scale of the instrument. The objection made to this contrivance was, that it is subject to derangement from slight accidental causes, as the collection of dust, and the wearing of the apertures in the silk indices. But Mr Keith improved his barometer farther, by adapting to it a clock, which turned a vertical cylinder, covered with paper ruled into 31 columns, for the days of the month, and a pencil attached to the *kneed* wire traced the oscillations of the column through its whole monthly course. At the commencement of each monthly period, a new paper was substituted for the old, which was preserved in the register of the weather.

This very ingenious instrument never came into much use, both on account of the expense, and because it was alleged that the continual friction of the pencil rendered slight changes of atmospheric pressure inappreciable.

Bryson's Improved Siphon Barometer. More recently a great improvement on the instrument of Mr Keith was contrived and executed by the late Mr Bryson, an eminent watchmaker of Edinburgh. Supplement.

This is also a siphon barometer, furnished with an ivory float, and *kneed* wire, ending in a small knife-edge, intended to mark the oscillations of the mercurial column. A vertical cylinder of japanned tinned iron, about three inches in diameter, moves round its axis once in every 24 hours. At one of its ends the hours from 1 to 12 A.M. are in red, and from 1 to 12 P.M. in black characters. Seven such cylinders are made, one for each day of the week. The cylinder for each day's observations has its surface thinly coated with a mixture of fine chalk and water, laid on with a camel-hair pencil. The cylinder fits accurately on a square arbor or spindle, which is steadily moved round by clockwork attached to the barometer. The knife-edge, instead of constantly pressing against the cylinder, is made to touch it only for a moment every hour, by means of a series of pins on the wheel connecting the clock with the cylinder. This slight touch is sufficient to cut through the thin film of chalk, and shew a black line on a white ground. There is therefore on the cylinder one such mark for every hour; and their position indicates the successive oscillations of the barometer.

When the day is completed, the cylinder is removed, and a fresh one substituted, and the first is fixed horizontally between two pivots, on which it is made to revolve steadily in what is termed the *reader.* On the front of the *reader* is a scale of inches from 27 to 32, divided into hundredths by means of a vernier, moved by a firm tangent screw, and ending upwards in a point. The precise value of each mark on the cylinder is thus ascertained.

This scale is first adjusted by simultaneous observations on a standard barometer. Should the scale be too high, the fixed pivot of the reader is loosened, and screwed out, until the point of the vernier corresponds to the indications of the standard barometer; after which the fixed pivot is permanently secured in its place for future observations.

The simple mechanism by which he has secured the steady movements of the cylinder in its horary revolution, and when transferred to the reader, is creditable to the skill of the inventor; and the barometer of Mr Bryson may be considered as probably the best register barometer hitherto constructed.

Specimen of Bryson's Hourly Barometric Register.

BAROMETRICAL MEASUREMENTS.

Barometrical Measurements.

It was remarked in the preceding article, that the decisive experiment by which Pascal established the reality of atmospheric pressure, had likewise suggested to this ingenious philosopher the method of determining the elevations of distant points on the surface of the globe. But the first attempts were very rude, proceeding on the inaccurate supposition that the lower mass of air is a fluid of uniform density. Different authors estimated variously from eighty to ninety feet as the altitude, which corresponds to a variation of the tenth part of an inch in the mercurial column. The Torricellian tube or cane, as it was then called, was, on its first introduction to England, carried accordingly to the tops of mountains, or conveyed to the bottom of pits and mines, or even let down to great depths in the sea.

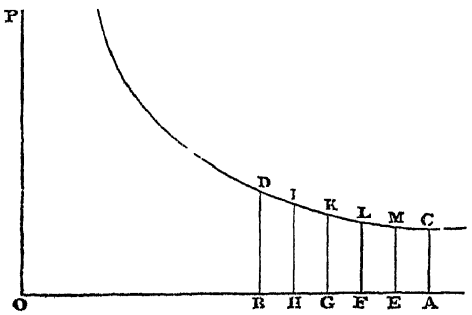
Sinclair.

Among those experimentalists who laboured most assiduously in the study and application of the barometer in this part of the island, we may mention George Sinclair. This ingenious person had been professor of philosophy in the university of Glasgow, but seems to have conscientiously resigned his office soon after the Restoration, rather than comply with that hated episcopacy which the minions of Charles II. had forced upon the people of Scotland. He then retired to the village of Tranent, not far from Edinburgh, and was employed as a practical engineer, in tracing the levels of coal-pits, in directing the machinery employed in the mines at Leadhills, and afterwards in the great undertaking of conducting water from the heights of the Pentlands to supply the northern metropolis. Though not a profound mathematician, he was skilled in mechanics and hydrostatics, and possessed no small share of invention. Sinclair is said to have been the first who applied to the mercurial tube the name of *baroscope*, or *indicator of weight;* the more definite appellation of *barometer*, or *measurer of weight*, not having been appropriated till many years afterwards. During his excursions in 1668 and 1670, he employed that instrument to measure the heights of Arthur's Seat, Leadhills, and Tinto, above the adjacent plains. He followed the original mode of using a tube sealed at the top, with a paper scale pasted against the side, which he carried to the top of the mountain, where he filled it with mercury; and, inverting it in a basin, he noted the altitude of the suspended column, and repeated the same experiment below; a very rude method, certainly, but no better was practised in England during the succeeding thirty years.

In a small scarce tract, printed in 1688, and bearing the quaint title of *Proteus bound with Chains*, Sinclair gives some judicious remarks on the variations of the barometer, considered as a weather-glass, and delivers very sound opinions, on the whole, respecting the causes of the chief meteorological phenomena. In a postscript to that piece, he proposes a most efficient and ingenious method of weighing up wrecks from the bottom of the sea. It consisted in employing two large arks, or square wooden boxes, fastened to the sides of the ship, and charged with air carried down to them by a succession of inverted casks, open at the lower end. An arc of a cubical shape, and twenty feet in every dimension, the smallest which he mentions, would, as he computes, have a buoyancy equivalent to 448,000 pounds Troy. It is remarkable that the celebrated Mr Watt always employed this very mode using a large gazometer, floating in a pond dug in the court of his manufactory, and charged gradually by the action of bellows, for raising the ponderous engines constructed at Soho, and lifting them over his walls into the boats, which were stationed to receive them in the adjacent canal.[1]

Barometrical Measurements.

In all the computations hitherto made from different altitudes of the barometer, the air was considered as a uniform fluid; no regard being had to the gradual diminution of density which must evidently take place in ascending the atmosphere. To estimate the effect of that gradation, it became requisite previously to determine the actual relation subsisting between the density of the fluid and its elasticity. This was first ascertained in England by Townley, who inferred, from some experiments of Boyle, that the elastic force which the air exerts is exactly proportional to its density. A similar conclusion was about the same time drawn by Mariotte, a French philosopher, from a still better series of experiments. Following out this very simple law, he thought of computing heights from barometrical observations, by the rules usually employed in constructing tables of logarithms; and had, therefore, obtained some glimpse, no doubt by a sort of conjectural process, of the remarkable result, that the density of the atmosphere decreases in a geometrical progression, corresponding to the elevations taken after an arithmetical one. But seemingly not aware of the importance of the principle at which he was pointing, Mariotte immediately deserted it; and calculating from a repeated bisection of the column of air between the two stations into successive horizontal strata, he contented himself with interpolating the densities according to a harmonic division, which he next abandoned for the simplicity of a series with equal differences. This able experimenter hence only sketched out a mode of investigating the problem of barometrical measurements, without arriving at any very definite or consistent rule of solution.



Relation of the air's density and elasticity.

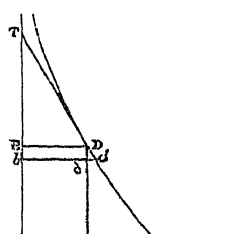
[1] Sinclair was author of a well-known little book entitled *Satan's Invisible World Displayed*, which, at a former period, was sold at all the public fairs in the country, and devoured with eagerness and dismay by the Scottish peasantry. In a quarto volume, on *Hydrostatics, and the Working of Coal-mines*, printed in Holland, and published by subscription in 1672, he digressed so widely from his subject as to insert *A True Relation of the Witches of Glenluce*. But this was the folly of the age, from which several of the most learned men had not been able to escape. It is painful to observe, that James Gregory, the inventor of the reflecting telescope, who, although endowed with talents of the highest order, appears to have had a keen temper, and to have imbibed an hereditary attachment to royalism and episcopacy, should have stooped to attack an unoffending and less fortunate rival. He wrote a little tract against Sinclair's *Hydrostatics*, with the title of the *Art of Weighing Vanity*, and under the thin disguise of Patrick Mather, archbeadle to the university of St Andrew's. It is a piece full of low scurrility, and memorable only for a very short Latin paper appended to it, containing the series first given to represent the motion of a pendulum in a circular arc. In the British Museum, there is a letter of Gregory to Collins, the secretary of the Royal Society, boasting of his project, and soliciting information with which to overwhelm the poor author. But with all his eagerness to hunt down Sinclair, he never touches on the strange episode of the Witches of Glenluce. What a picture of times approaching so near to our own! Sinclair was restored to his chair at the Revolution, and lived a few years longer. He answered Gregory's attack in the same coarse style, charging him with total want of skill in the use of astronomical instruments, though by help of subscriptions he had erected a sort of observatory at St Andrew's. The manuscript of this reply is preserved in the College Library of Glasgow.

Barometrical Measurements.

Relation of atmospheric density and elevation.

In 1686 that ingenious and active philosopher Dr Halley resumed the subject, and discovered the law that connects the elevation of the atmosphere with its density; of which he gave a clear demonstration, derived from the well-known properties of the hyperbola referred to its asymptotes.[1] Since the height of the mercury indicates the pressure, and consequently the elasticity of the external air, it must be proportioned likewise to the density. Wherefore the breadth of a given mass of air, or the thickness of a stratum which corresponds to a certain portion of the mercurial column, will be inversely as this altitude. Let O be the centre of a rectangular hyperbola, of which OA and OP are the asymptotes; and conceive the distances OA and OB to represent the heights of the mercury at two stations. The perpendiculars AC and BD, which are reciprocally as OA and OB, must hence express the relative thickness of strata corresponding to equal portions of the barometric scale. Divide AB into a multitude of equal segments, and erect the perpendiculars EM, FL, GK, and HI. The intercluded spaces, from AC to BD, will denote the successive thickness of the series of strata into which the whole mass of air between the two stations is subdivided. Consequently the aggregate or mixtilineal space DBAC, which is proportional to the logarithm of the ratio of OB to OA, will express the difference of atmospheric elevation when the mercurial column mounts from B to A. Taking equal ascents, therefore, in the atmosphere, the corresponding densities must, from the property of the hyperbola, form a decreasing geometrical series.

Rule deduced.



To apply this elegant theorem, Dr Halley availed himself of the best experiments which had been performed to determine the relative densities of air, water, and mercury. In different trials made near the earth's surface, it was found, when the barometer stood at 29¾ inches, that the air is 840, 852, or even 860 times lighter than water. Employing round numbers, therefore, and assuming the specific gravity of mercury to be 13½, he reckoned $800 \times 13\frac{1}{2} \times 30 = 10{,}800$ inches, or 90 feet, as the altitude of an atmospheric column which, near the level of the sea, would exert a pressure equivalent to that of an inch of mercury. For the co-efficient, which answers to the actual constitution of the atmosphere, Halley should have taken the thirtieth part of ·4342945, the modulus of the common system of logarithms, or ·0144748. But he proceeded less directly, having satisfied himself with taking the arithmetical mean between the differences of the logarithms of 29 and 30, and of those of 30 and 31; a compensation of errors which gives ·0144765, hardly deviating from the former. Hence he gave this simple analogy for computing the heights of mountains by the barometer: *As the constant number* ·0144765 *is to the difference between the logarithms of the barometric columns at the two stations, so is* 900 *feet to the elevation required.* The result of this operation is evidently the same as if the logarithmic difference had been multiplied by the number 62170; a very tolerable approximation at all seasons for a northern climate, and quite accurate, indeed, if the mass of intervening air had a medium temperature of 46° by Fahrenheit's scale. Dr Halley supposed that the observations themselves might, from the influence of heat, differ about a fifteenth part between summer and winter. But the thermometer was still so imperfect an instrument, that it could not be applied with confidence in correcting such variations.

Barometrical Measurements.

Otherwise investigated.

The principle which Halley thus investigated might be derived from a simpler process. Conceive the atmosphere to be divided into a multitude of equally thin horizontal layers, it is evident that each successive stratum would, to the pressure of the superincumbent stratum, add its own weight, which being as its density or elasticity, is therefore proportioned to the collective pressure; and, consequently, those densities must continually increase in going downwards, exactly in the same way, and after a like progression, as money accumulates at compound interest, where a constant portion of the aggregate fund is regularly joined to the capital.[2] Such, in fact, is the distinguishing character of a geometrical progression, that the increase or decrease of each succeeding term is always proportional to the term itself. The logarithmic curve is hence the best adapted for exhibiting the relations which connect the densities with the elevations in the atmosphere; the axis of the curve expressing the elevation, while each ordinate represents the corresponding density of the stratum of air. It being a fundamental property of the logarithmic curve, that every subtangent applied to it has the same length, the exact determination of this in the case of our atmosphere is the only thing wanted for the final solution of the general problem.

Let AB, the abscis of a logarithmic curve, represent a line descending perpendicular through the atmosphere; the ordinates AC and BD will indicate the elasticity of the strata at A and B, and consequently, abating the influence of temperature, their densities. Draw the tangent DT, and form the elemental triangle $Dd\delta$; then BD : BT :: δd : δD, or inversely BD : δd :: BT : δD. But the thickness δD of each accrescent stratum being assumed to be the same, and the subtangent being constant, from the nature of the curve; the ratio of BT to δD is given; therefore the ratio of BD to δd is likewise given, or the increment of the density in the successive strata is proportional to

[1] It appears, however, that he was anticipated by Huygens, who had found, as early as the year 1662, that the altitudes of successive strata of air being taken in arithmetical progression, the corresponding densities will form a geometrical series. This beautiful proposition he never published, indeed, but left it recorded upon one of the blank leaves of a Dutch almanac, containing various other speculations, and now preserved in the library of the university of Leyden.

[2] To illustrate still further this comparison; if we reckon the mean altitude of a uniform atmosphere to be 26000 feet, it will follow that, for every descent of 26 feet, the density of the air will increase one thousandth part. This rate of progression corresponds precisely with the weekly improvement of money invested at 5 per cent. per annum, supposing, for the sake of simplicity, the year to contain only 50 weeks. Since money at the statute interest doubles in 14½ years, so the air has its dilatation doubled at the height of $26 \times 50 \times 14{\cdot}2$ or 18466 feet, answering to three miles and a half.

Barometrical Measurements.

the density itself, the leading property of air. The pressure of the thin stratum at B is represented by BD*db*, which is equal to the rectangle under BT and *bd*. Hence, drawing the parallel DE, the collective area ABDC, which represents the weight of the atmosphere between the altitudes A and B, is equal to the rectangle under the subtangent and EC. But AB expresses the difference of the logarithms of the ordinates AC and BD, or the densities at A and B; and consequently this difference multiplied by the length of BT will indicate AB. In relation to our atmosphere at the point of congelation, the numerical value of the subtangent is about 26,000 feet, which is very nearly the product of 60,000 into the *modulus* of the ordinary logarithms.

Eleven years after Dr Halley had given his rule for barometrical measurements, this philosopher had an opportunity of applying it to discover the height of Snowdon in North Wales. He found that the barometer which stood at 29·9 inches on the sea-shore near Caernarvon, fell a few hours after, when planted on the summit of the mountain, to 26·1 inches, the altitude having been ascertained previously, by a trigonometrical observation, to be 1240 yards.

Newton's general solution.

The year 1687 is memorable as being the date of the first publication of the *Principia*, which was drawn up chiefly at the urgent request of Halley, from disjointed materials that had lain a considerable time in the author's closet. In that immortal work, Newton resumed the problem of the gradation of atmospheric density, and solved it in that general way which suited his penetrating genius. He demonstrated that, supposing the particles of air, like other bodies, to have their weight or gravitating tendency diminished as the squares of their distances from the centre of the earth, if those distances be taken in harmonic progression, the corresponding densities of the atmosphere will form a geometrical one. But since the diminution of attraction at the greatest height we are able to reach amounts only to the two thousandth part of the whole, this difference is too minute to be adopted in practice; and the simpler law first established by the sagacity of Halley may be deemed sufficiently accurate for every real purpose.

Newton has given a sort of geometrical solution of the problem. But a more precise, and, in this case, a clearer investigation, is obtained by help of the symbols of the integral calculus. Let x and x' express the altitudes of two strata of atmosphere, y and y' the corresponding densities, r the radius of the earth; and suppose further, that e represents the altitude of the equiponderant column which measures the elasticity of the air. Since the density of the air depends on the incumbent pressure, its decrement must evidently be proportional to the weight of each superadded minute stratum, or to the density of this stratum multiplied into its thickness and power of gravitation.

Whence $-edy = ydx\left(\frac{r}{r+x}\right)^2$, or $-\frac{edy}{y} = \frac{r^2dx}{(r+x)^2}$,

of which the complete integral is e Hyp. Log. $\frac{y'}{y} = \frac{r^2}{r+x} - \frac{r^2}{r+x} = \frac{r^2}{r+x}\cdot\frac{x'-x}{r+x'}$. If r be regarded as indefinitely great in comparison of x, the expression will pass into e Hyp. Log. $\frac{y'}{y} = x' - x$, which is only the common formula.

Application of the thermometer.

Little seemed wanting, therefore, to complete the practice of barometrical measurements, but the application of the thermometer to correct the results. This instrument, however, advanced slowly to perfection, and more than forty years yet elapsed before it came into current use. Some of the continental philosophers likewise, biassed, perhaps, by a secret jealousy of the superiority which England had acquired in science, began to throw out doubts respecting the reality or accuracy of the law of geometrical progression in the atmosphere. Daniel Bernoulli, a man of candour on the whole, as well as ingenuity, but who, with some proneness to speculative reasoning, had unfortunately imbibed many of the prejudices of the Cartesian and Leibnitzian schools, proposed in his capital work, the *Hydrodynamica*, which appeared in 1736, some vague hypotheses regarding the constitution of the atmosphere, as deduced from certain internal motions attributed to its component strata. The specious results of those calculations led him hastily to deviate from the principle of the geometrical progression of density in the upper regions. In this departure from nice theory he was followed by Cassini and Horrebow, who concluded, from some partial observations they had made, that the barometer, in its indications of atmospheric pressure, is subject to irregularity; and that, near the surface of the earth, it obeys a different law from that which obtains at great elevations. A strong light, however, was thrown upon the subject in 1753 by Bouguer, an able mathematician and very skilful and ingenious observer, who, with other academicians, had been employed for several years in measuring a degree of the meridian along the stupendous ridge of the Andes. From the comparison of more than thirty distinct observations, he deduced a simple and elegant rule for computing heights by means of the barometer. It is this, that the difference between the logarithms of the mercurial columns at the two stations being *diminished* by one thirtieth part, and the decimal point shifted four places to the right, will express the required elevation in *toises*. Since the English was to the French foot nearly as fifteen to sixteen, the rule would be accommodated to our measures, and the result expressed in feet, if the logarithmic difference were *augmented* by the thirtieth part, then multiplied by six, and the decimal point thrown back four places; or, which is the same thing, if that logarithmic difference were multiplied at once by 62,000. But Bouguer imagined, that this rule would not hold exactly in Europe, or in the lower regions of the torrid zone; and to explain the deviation, he had recourse to the forced supposition that the particles of air possess different degrees of elasticity. Lambert, a philosopher of great originality and penetration, afterwards published some excellent remarks on the comparison of barometrical measurements. But no material progress was made till 1755, when M. de Luc of Geneva resumed the subject, and carefully combined experiment with observation. For the space of fifteen years and upwards, he prosecuted his inquiries with diligence and perseverance, aided by the peculiar advantages of local situation, in a city abounding with skilful artists, and seated in the neighbourhood of lofty mountains. The discrepancies which had hitherto created so much embarrassment proceeded mostly from the inattention of observers to the disturbing influence of heat, and particularly its effect in expanding the air, and consequently augmenting the elevation due to a given difference of atmospheric pressure. De Luc's first object was to improve the thermometer of Reaumur, which, though greatly inferior to that of Fahrenheit, had been adopted in France and the adjacent parts of the Continent. Having ascertained that mercury has the valuable property of expanding equably with equal additions of heat, he substituted that metallic fluid for spirit of wine, but retained its arbitrary and inconvenient scale of eighty degrees between the points of freezing and boiling water. He next examined the dilatation of air

Bouguer.

De Luc.

Barometrical Measurements.

at different temperatures, and corrected those results by numerous observations made on the mountains of Savoy, and the mines of the Hartz, in which the barometer was combined with the thermometer. The *formula* which he thence deduced for the computation of barometrical measurements was, in 1772, published in his *Recherches sur les Modifications de l'Atmosphère*, and seemed to attract, especially in England, a very considerable degree of notice. Dr Maskelyne, the astronomer-royal, adapted it to our system of measures, and De Horsley made annotations and comments on it. But, what was of more importance, other accurate observers, incited by De Luc's example, entered the same field of inquiry, provided with instruments of greater delicacy and much better construction.

Shuckburgh,

In 1775 Sir George Shuckburgh Evelyn visited the Alps, and combined trigonometrical operations with corresponding observations by barometers and thermometers from the hands of Ramsden; and about this time likewise,

and Roy.

General Roy not only measured, with instruments made by that excellent artist, some of the principal mountains in Scotland and Wales, but instituted a series of manometrical experiments. It resulted from all these researches that, for each degree on Fahrenheit's scale, mercury expands the 9700th part, and air the 435th part of their respective bulks. It further appeared that the atmosphere has its temperature almost uniformly diminished at equal ascents; and that the logarithmic difference, reckoning as integers the first four digits, expresses in English fathoms the height of an aërial column as cold as the point of congelation. General Roy proposed likewise another correction depending on the enfeebled gravity, and consequently the augmented altitude, of the equiponderant column of atmosphere in the lower latitudes, occasioned by the influence of centrifugal force arising from the earth's rotation. Several years afterwards, Professor Playfair, in a learned paper, printed in the first volume of the *Transactions of the Royal Society of Edinburgh*, examined all the circumstances which can affect barometrical measurements, and discussed each question with the correctness and perspicuity that we might expect from his distinguished abilities. At nearly an equal interval of time the celebrated Laplace resumed the subject in his *Mécanique Céleste*, and brought all the conditions together in a very complicated formula. Such an appearance of extreme accuracy, however, is perhaps to be regarded merely as a theoretical illusion, unsuited and inapplicable to any real state of practice. Biot has since attempted to arrive at a similar conclusion, by setting out *à priori* from some careful experiments on the relative density of air and mercury, performed by him in conjunction with Arago. He thence infers that, in the latitude of Paris, and at the point of congelation, air, under a mercurial pressure of 76 metres, or 29,922 English inches, is 10,463 times lighter than mercury at the temperature of water at its lowest contraction. This would give 26,090 feet for the height of a column of homogeneous fluid, whose pressure is equivalent to the elasticity of the atmosphere. The co-efficient adapted to common logarithms, and adjusted to the force of attraction at the level of the sea, would therefore be 60,148 feet, or 18,334 metres; scarcely differing sensibly from the quantity which Ramond had deduced from a very numerous set of experiments made by him on the Pyrenees. But Biot prefers, as the co-efficient, the number 18,393, answering for an elevation of 1200 metres, or about 4000 feet above the sea, which is not far from the general level of such observations. The formula is hence, in English feet,

Formula of Laplace.

$$60{,}346\ (1 + \cdot 002837 \cos. 2\psi)\left(1 + \frac{2(T+t)}{1000}\right) \log. \frac{H}{h};$$

where ψ denotes the latitude of the place, T and t the temperatures of the air at the two stations, as indicated by the centesimal thermometer, and H and h the heights of mercurial columns corrected for the effects of heat.

Barometrical Measurements.

This active writer has likewise given tables for expediting the calculation of barometrical measurements; in which he was anticipated, however, by Oltmans of Berlin, who published, in 1809, large *Hypsometrical Tables*, as they are called, accommodated to the complex formula of Laplace. Such tables might no doubt prove useful where very frequent computations are wanted, as in the case of the reduction of the numerous observations brought home by Baron Humboldt, for which, indeed, they were first designed. But still they contain a needless profusion of figures, and hold forth a show of extreme accuracy which the nature of the observations themselves can never justify. The mere calculation of barometrical measurements is a secondary object. The great difficulty is to procure good observations, and to combine tolerable accuracy with expedition. For this purpose, a very portable barometer is still wanted;—an instrument light and commodious, exempt from injury or derangement, and yet sensible to minute changes of atmospheric pressure. These properties, indeed, are seldom conjoined, and one advantage must generally be sacrificed to obtain another. A modification of the conical barometer already suggested would seem, on the whole, to be well adapted for the geological traveller. The two unequal tubes are cemented into a small cylinder of steel, with a fine stop-cock of the same metal confining the mercury. This renders the instrument so portable that it may be inclosed in a walking-stick; on turning the steel-cock, and inverting the staff, the height of the mercurial column is readily found.

Mountain barometer. Pl. CIV.

A barometer of the most improved construction is represented in fig. 19; a portion of the tube is shown in fig. 20; and a section of its cistern in fig. 21. By help of a screw pressing against the bottom of a leathern bag, inclosed within a cylindrical ivory box, the mercury is always brought up through a tubular aperture to the same precise level; or till its convex surface appears to touch a very thin line of light, which is admitted through a slip of ivory applied against the side of the chink or separation of this tube from a wider one immediately over it. The lower end of the mercurial column being thus adjusted, the length is easily measured by drawing gradually down a hollow brass tube, divided at intervals by wide slits, covered on one side by thin bits of ivory, till by that softened light a contact is observed with the edge of a slit and the convex top of the column. The fine Vernier which the movable tube carries gives the altitude of the mercury in thousandth parts of an inch. A thermometer is likewise constantly attached to the instrument, for the purpose of indicating the temperature of the mercury, which, from the heat of the hand in carrying, or the influence of the solar beams, is commonly warmer than the external air.

This mountain barometer is suspended for observation by jimbols from a tripod, as exhibited in fig. 18; but its several parts can be folded up together into a convenient compass, tolerably well fitted for carriage, as represented in fig. 19. The whole apparatus may not exceed the weight of ten pounds; yet even this, moderate as it might seem, would be felt a serious encumbrance by a traveller who is engaged, day after day, in the labour of climbing mountains. The risk which the instrument incurs, besides, in transporting it perhaps over rough precipices, imposes a perpetual constraint, while to make correct observations with it must always require time and patient attention. A lighter and more compact, though less accurate, barometer will generally be preferred by the geo-

Barometrical Measurements.

logical traveller, whose object is rather to extend our acquaintance with the altitudes of mountains, than to aim at a superfluous and often illusory precision. The portable instrument, invented by Sir Henry Englefield, and represented in fig. 14, will, on the whole, answer those views. Its cistern is formed of box-wood, sufficiently tight to hold the mercury, without preventing the access and impression of the external air. When this barometer is inverted, the mercury, therefore, subsides very slowly in the tube, which must be firmly suspended in a vertical position. For greater security, the mercury is now put into a leathern bag introduced within the cistern.

Portable barometer of Sir H. Englefield, and of Gay-Lussac.

A very simple and convenient sort of portable barometer was lately invented in France by that celebrated chemical philosopher M. Gay-Lussac. (See fig. 15 and 16.) It consists of rather a wide siphon tube, filled with mercury, and sealed hermetically at the inverted end, having a very fine capillary hole formed about an inch under this, by nicely directing the flame of a blow-pipe against the side of the glass, and drawing a melted spot of it out to a point. The lower portion of the principal branch has its bore contracted to less than the tenth part of an inch, to prevent the mercurial column from dividing in the act of inverting it. The mercury is boiled as usual, and the tube may be concealed in a walking-stick, or lodged, like the complete mountain barometer, in a cylinder of brass, with movable sliders bearing the divisions of a Vernier at both ends. (See fig. 17.) For greater simplicity, however, the larger divisions might be engraved on the tube itself. This kind of barometer is of ready use, and very little exposed to hazard in carriage. It is commonly held in a reclined or inverted position; but, in making an observation, it must be gently turned back, and kept perpendicular till the mercury descends through the contracted bore, and slowly rises again in the opposite short branch; the scale is noticed at both ends of the incurved column, and the difference of those indications gives its correct altitude.

Modified conical barometer.

A modification of the conical barometer, which, in travelling, we have ourselves employed with great ease and advantage, should likewise be mentioned. The principal part of it consists of a small stop-cock made of steel, and represented in fig. 13. A glass tube of 31 or 32 inches long, with a bore of the tenth part of an inch hermetically sealed at the top, and filled with quicksilver, is cemented into the one end of the stop-cock; and into the other end is cemented an open and wider tube, 16 inches or more in length, and having its diameter above the eighth part of an inch. This compound tube is lodged in a walking-stick, divided into inches and tenths through its whole extent, or only at the upper part, if uniform tubes be selected. In making an observation, the cock is turned, and the instrument inverted. The upper column then descends partly into the lower tube, till it becomes shortened to the proper altitude.

We have already stated the principles on which the calculation of barometrical measurements proceeds. But there still are some points, either assumed or overlooked, which may considerably modify the results. It is presumed, that, at equal successive heights, the temperature of the atmosphere decreases uniformly. This property, however, does not hold strictly, and it may be shown, from a comparison of the best observations, that the decrements of heat follow a quicker progression in the higher regions. But we shall soon have another opportunity to examine this subject, and trace out its various consequences.

The humidity of the air also materially affects its elasticity, and the hygrometer should therefore be conjoined with the thermometer in correcting barometrical observations. But nothing satisfactory has yet been done in regard to that subject. The ordinary hygrometers, or rather hygroscopes, are mere toys, and their application to science is altogether hypothetical. A most unphilosophical course has lately been pursued, by multiplying calculations grounded on very loose data, instead of instituting a nice and elaborate train of original experiments.

Barometrical Measurements.

In the actual state of physical science, it is preposterous, therefore, to affect any high refinement in the formula for computing barometrical measurements. The whole operation may be reduced to a very short and easy process. But the simplicity of the calculation would be still greater, if the centesimal thermometer were generally adopted. It will be sufficiently accurate, till better data are obtained, to assume the expansion of mercury by heat as equal to the 5000th part of its bulk for every centesimal degree, while that of air is twenty times greater, being an expansion for each degree of the 250th part of the bulk of this fluid. 1. *Correct the length of the mercurial column at the upper station, adding to it the product of its multiplication into twice the difference between the degrees on the attached thermometers, the decimal point being shifted four places to the left. 2. Subtract the logarithm of this corrected length from that of the lower column, multiply by six, and move the decimal point four places to the right; the result is the approximate elevation expressed in English feet. 3. Correct this approximate elevation by shifting the decimal point three places back to the right, and multiplying by twice the sum of the degrees on the detached thermometers; this product being now added, will give the true elevation.*

Rule for computing barometrical measurements.

If it were judged worth while to make any allowance for the effect of centrifugal force, this will be easily done before the last multiplication takes place, by adding to twice the degrees on the detached thermometers the fifth part of the mean temperature corresponding to the latitude. The mean temperature itself is formed by multiplying the square of the cosine of the latitude by twenty-nine.

Examples.

In illustration of these rules, we shall subjoin some real examples. General Roy, in the month of August 1775, observed the barometer on Caernarvon Quay, at 30·091 inches, the attached centesimal thermometer indicating 15°·7, and the detached 15°·6; while, on the peak of Snowdon, the barometer fell to 26·409 inches, and the attached and detached thermometers marked respectively 10°·0 and 8°·8. Here twice the difference of the attached thermometers is 11°·4, and twice the sum of the detached thermometers is 48°·8, which becomes 50·8 when augmented by the fifth part of the mean temperature on that parallel. Now, omitting the lower decimals, the first correction is ·00264 × 11·4 = ·030, to be added to 26·409. Wherefore,

Log. 30·091	= 1·4784866
Log. 26·439	= 1·4223450
Difference	= ·0561416
Constant multiplier	= 60000
Approximate height	= 3368·496

And, for the true height, the correction is 3·37 × 50·8 = 171·2, which gives 3340 for the final result.

We shall take another example from the observations made by Sir George Shuckburgh Evelyn, at the same period, among the mountains of Savoy. This accurate philosopher found the barometer, placed in a cabin near the base of the Mole, and only 672 feet above the surface of the lake of Geneva, to stand at 28·152 inches, while the attached and detached thermometers indicated 16°·3 and and 17°·4; but, in another barometer carried to the summit of that lofty insulated mountain, the mercury sunk to 24·176 inches, the attached and detached thermometers marking 14°·4 and 13°·4. Wherefore, twice the difference

Barometrical Measurements.

of the degrees on the attached was 3°·8, and twice the sum of the degrees on the detached thermometers was 61°·6. Consequently the correction to be applied to the higher column was ·0024 × 3·8 = ·009, which makes it 4·185. Now,

Log. 28·152 =	1·4495092
Log. 24·185 =	1·3835461
Difference =	·0659631
Constant multiplier =	60000
Approximate elevation =	3957·786

To correct this approximate elevation, remove the decimal point three places back, and multiply it by 61°·6, increased by 2°·9, the fifth part of the mean temperature, corresponding to the latitude; but 3·96 × 64·5 = 255·4, and 3957·8 + 255·4 = 4213. Hence the summit of the Mole is 4885 feet above the lake of Geneva, or 6083 feet above the level of the Mediterranean Sea.

The last example we shall give is drawn from the observation which Baron Humboldt made among the Andes, near the summit of Chimboraço, the highest spot ever approached by man. This celebrated traveller found there, that the barometer fell to 14·850 English inches; the attached thermometer in the tent being at 10°, and the detached in open air being 1°·6 under zero. But the same barometer, carried down to the shore of the Pacific Ocean, rose exactly to thirty inches, while both the attached and detached thermometers stood at 25°·3. Consequently the correction to be applied to the upper column is = ·0015 × 30·6 = ·045. Wherefore,

Log. 30·000 =	1·4771213
Log. 14·895 =	1·1730405
Difference =	·3040808
Constant multiplier =	60000
Approximate elevation =	18244·848

Now, the difference of the detached thermometers, or 26°·9, being doubled and further increased by 5°·8, the fifth part of the mean temperature at the equator, makes 59°·6; and the final correction to be applied is therefore = 18·24 × 59°·6 = 1087, which gives 19,332 feet for the true elevation observed, or 2140 feet below the summit of Chimboraço.

Calculation without logarithms.

These calculations are performed by the help of logarithms. It is desirable, however, to approximate at least to barometrical measurements without such aid. A very simple rule for this object has been given by Professor Leslie in his *Elements of Geometry*. Since $\log.\frac{a}{b} = 2\,M\left(\frac{a-b}{a+b} + \frac{1}{3}\left(\frac{a-b}{a+b}\right)^3 + \frac{1}{5}\left(\frac{a-b}{a+b}\right)^5 \text{ \&c.}\right)$, where M denotes the modulus of the logarithmic system; when a approaches to b, the lower terms may be rejected without sensible error, or $\log.\frac{a}{b} = 2\,M\left(\frac{a-b}{a+b}\right)$, very nearly.

Wherefore, in reference to our atmosphere, the modulus is expressed by the equiponderant column of homogeneous fluid, or 60,000 × ·4342945 = 26,058 feet, or only 26,000 in round numbers; whence, *as the sum of the mercurial columns is to their difference, so is the constant number* 52,000 *feet to the approximate height.* Let General Roy's observation on Snowdon be resumed as an example: the analogy is 30·091 + 26·439 : 30·091 — 26·439, or 56·530 : 3·652 : : 52,000 : 3,359, the approximate elevation, differing very little from the logarithmic result.

This mode of calculation may be deemed sufficiently accurate for determining any altitude that exceeds not 5000 feet. But it will extend to greater elevations if the second term of the series be likewise taken, which is done by striking off three figures, and cubing the half of this number. Thus, resuming the mensuration of Chimboraço, 44·895 : 15·105 : : 52,000 : 17,496, and $(8·75)^3 = 670$, making together 18,166 for a nearer approximation.

Barometrical Measurements.

Barometric scale.

The calculation of barometrical measurements, including the corrections required, is rendered most easy and expeditious by means of a sliding rule made by Mr Cary, optician in London. This small instrument should always go along with mountain barometers; and it will be found a very agreeable companion to every geological traveller.

But portable barometers, in spite of every precaution, are yet so liable to be broken or deranged, that other auxiliary methods are desirable for ascertaining distant elevations. In this view, the variation of the boiling point of water was proposed by Fahrenheit as far back as the year 1724; the idea having occurred to him, as it had done before to Amontons, while engaged with experiments to perfect his thermometer. Little regard, however, seems to have been paid to the suggestion till De Luc and Saussure made a series of observations on the heat of ebullition at different elevations above the surface. About thirty years since, Cavallo attempted to revive the scheme of Fahrenheit, but experienced much difficulty in preventing the irregular starts of the thermometer plunged in boiling water. The best and surest way of examining the heat of ebullition, is to suspend the bulb of the thermometer in the confined steam as it rises from the water.

Temperature of boiling water applied to the mensuration of heights.

The heat at which water boils, or passes into the form of steam, depends on the weight of the superincumbent atmosphere. By diminishing this pressure, the point of ebullition is always lowered. It appears that, while the boiling heat sinks by equal differences, the corresponding atmospheric pressure decreases exactly, or at least extremely nearly, in a geometrical progression, it being found that every time such pressure is reduced to one half, the temperature of boiling water suffers a regular diminution of about eighteen centesimal degrees. This beautiful relation assimilates with the law which connects the density and elevation of the successive strata of the atmosphere. The interval noticed between the boiling points at two distinct stations must be proportional to their difference of altitude above the level of the sea. We have, therefore, only to determine the co-efficient or constant multiplier, which may be discovered either from an experiment under the rarefied receiver of an air-pump, or from an actual observation performed at the bottom and on the top of some lofty mountain. We shall prefer at present the observation made by Saussure on the summit of Mont Blanc. This diligent philosopher found, by means of a very delicate thermometer constructed on purpose, that water which boiled at 101°·62 in the plain below when the barometer stood at 30·534 English inches, boiled at 86°·24 on the top of that mountain, while the barometer had sunk to 17·136. Wherefore the distance between the points of ebullition, or 15·38 centesimal degrees, must correspond to an approximate elevation of 15,050 feet, which gives 978½ feet of ascent for each degree, supposing the mean temperature of the atmospheric column to be that of congelation. But it will be more convenient to assume 1000 for the constant multiplier, which corresponds to the temperature of 5½°.

To reduce this very simple result into practice, it would be requisite to have a thermometer with a fine capillary bore, and nicely constructed, the stem six or eight inches long, and bearing ten or a few more degrees from the boiling point; these degrees to be divided into twenty or perhaps fifty equal parts engraved on the tube, which should be rather thick, and terminating in a bulb of about half an inch diameter. This thermometer, being fitted

Barometrical Measurements || Baron.

with a brass ring two inches above the bulb, should screw into the narrow neck of a small copper flask, which holds some water, but has a hole perforated near the top for allowing the steam to escape. The water may be made to boil by the application of a lamp. The difference between the indications of the thermometers at the two stations being multiplied by a thousand feet, will give the elevation corresponding to a temperature of $5\frac{1}{2}°$. The correction for the actual mean temperature can easily be applied. If a more correct co-efficient be afterwards determined, the same thousand, retained as a multiplier, may easily be adapted to another temperature.

Mode of tracing vertical sections.

This method of measuring elevations on the surface of the globe is, therefore, capable of great improvement, and might be employed with advantage in a variety of cases where observations with the barometer are not easily obtained. Its application would be most important to physical geography, in ascertaining the capital points for tracing the outline of the profile or vertical section of any country. The common maps, which exhibit mere superficial extension, are quite insufficient to represent the great features of nature, since the climate and productions of any place depend as much on its elevation above the sea as its latitude. Scientific travellers have accordingly turned their attention of late years to the framing of vertical sections. As a specimen, we give, in fig. 22, from Humboldt's *Geography of Plants*, a section across the American continent, one of the best and most interesting that has yet appeared. It consists, in fact, of four combined sections, traversing through an extent of 425 miles. The line begins at Acapulco, on the shore of the Pacific Ocean, and runs 195 miles, about a point of the compass towards the east of north, to the city of Mexico; then 80 miles, a point to the south of east, to La Puebla de los Angeles; again it holds a north-east direction of 70 miles, to the Cruz Blanca; and finally bends 80 miles east by south, to Vera Cruz, on the coast of the Atlantic. A scale of altitudes is annexed, which shows the vast elevation of the table-land of Mexico. An attempt is likewise made in this profile to give some idea of the geological structure of the external crust. *Limestone* is represented by straight lines slightly inclined from the horizontal position; *Basalt*, by straight lines slightly reclined from the perpendicular; *Porphyry*, by waved lines somewhat reclined; *Granite*, by confused hatches; *Amygdaloid*, by confused points.

Barometrical Measurements || Baron.

The Caspian below the level of the ocean.

By this mode of distant levelling, a very interesting discovery, in another quarter of our globe, was made by Engelhardt and Parrot, two Prussian travellers. They proceeded, on the 13th July 1814, from the mouth of the Kuban, at the island of Taman, on the Black Sea; and, examining carefully every day the state of the barometer, they advanced with fifty-one observations, the distance of 990 wersts, or 711 English miles, to the mouth of the Terek, on the margin of the Caspian Sea. Similar observations were repeated and multiplied on their return. From a diligent comparison of the whole, it follows that the Caspian is 334 English feet below the level of the Black Sea.[1] That the Caspian really occupies a lower level than the Ocean, had been suspected before, from a comparison of some registers of barometers kept at St Petersburg, and on the borders of that inland sea; but the last observation places the question beyond all doubt. It further appears, that within 250 wersts, or 189 miles, of the Caspian, the country is already depressed to the level of the Ocean, leaving, therefore, an immense basin, from which the waters are supposed to have retired by a subterranean percolation.

If the same plan of barometrical measurements had been followed by the adventurous explorers of the African continent, and the altitudes of the central lakes ascertained, the question regarding the course of the Niger would have been much sooner settled, and much vague and unsatisfactory discussion avoided. Even thermometrical observations of the temperature of springs, or of the ground at moderate depths, would have furnished an approximation to those elevations sufficiently near for solving that great problem in geography on scientific principles alone.

The spirit of modern enterprise has more lately carried barometers to the remotest and loftiest stations on the surface of our globe. It has been thus ascertained that some of the mountains in the equatorial parts of America attain the stupendous altitude of 25,000 feet, while the great chain of Upper India seems to rear its vast summit about 2000 feet still higher. See CLIMATE, HYGROMETRY, and METEOROLOGY. (J. L.)

BARON. The origin and primary import of this term have been much contested. Menage derives it from the Latin *baro*, a word which we find used for *vir*, a "stout" or "valiant man;" whence it was that those placed next the king in battles were, according to him, called *barones*, as being the bravest men in the army; and as princes frequently rewarded with fees the bravery and fidelity of those about them, the word came to signify any noble person who held a fee immediately of the king. Isidore, and after him Camden, suppose the word, in its original acceptation, to have meant a "mercenary soldier;" and Messieurs de Port Royal derive it from βάρος, "weight" or "authority." But Cicero uses the word *baro* for a stupid brutal man; the old Germans make mention of "buffeting a baron," meaning a villain; and the Italians use the word *barone* to signify a "beggar." M. de Marca thinks baron derived from the German *bar*, "man," or "freeman;" others seek its origin in the old Gaulish, Celtic, and Hebrew languages; and some are of opinion that it comes from the Spanish *varo*, a "stout noble person;" whence wives used to call their husbands, and princes their tenants, "barons." In the Salic law, as well as in the laws of the Lombards, the word *baron* signifies *man* in general; and, accordingly, the old glossary of Philomenes renders baron ἀνήρ, "man." The old law expression "*baron* and *feme*" (man and wife) preserves the traces of this signification.

The term is more particularly applied among us to a lord or peer of the lowest class, or a degree of nobility next below that of viscount. In ancient records the word *baron* included all the nobility of England, because all noblemen were barons even although they occupied a higher rank in the peerage. But it sometimes happened, that, when a baron had been raised to a new degree of peerage, the two titles, in the course of a few generations, descended differently, one perhaps to the male descendants, and the other to the heirs-general, by which means the earldom or other superior title subsisted without a barony; and there are also modern instances where persons have been created earls and viscounts without annexing a barony to their other

[1] The trigonometric measurement, however, of Fuss, Sabler, and Sawitsch, make the depression of the Caspian much less, being only 81.4 English feet.

Barons. honours; so that now the rule does not hold universally that all peers are barons.

The origin and comparative antiquity of barons have been the subject of much research amongst English antiquaries. But the most probable opinion is, that they were the same with our present lords of manors; to which the appellation of *court-baron*, which is the lord's court, and incident to every manor, seems to give countenance. The original name of this dignity in England is said to have been *vavassour*, which by the Saxons was changed into *thane*, and by the Normans into *baron*. From Magna Charta it appears that originally all lords of manors, or barons, had seats in the great council or parliament; but such is the defective state of the public records, that the first precept to be found is not of older date than the 49th of Henry III.; and this, though it had been issued out in the king's name, had neither his authority nor his sanction, the king himself, his son Prince Edward, and most of the nobility who remained faithful to him, being then prisoners in the hands of the rebellious barons.

Before the date above mentioned, the ancient parliaments consisted of archbishops, bishops, abbots, earls, and barons. Of these barons there were two sorts; the greater barons, or the king's chief tenants, who held *in capite* of the crown; and the lesser barons, who held of the greater by the tenure of military service. The former had a summons to parliament by several writs; and the latter, if possessed of thirteen knights' fees and a quarter, had a general summons from the sheriff in each county. At the date above given, instead of keeping to the old form, the prevailing powers thought fit to summon only those of the greater barons who were of their party, and, in room of the lesser barons who attended with large retinues, to issue their precepts to the sheriffs of counties to cause two knights in every shire to be chosen, and one or two burgesses for each borough, to represent the people residing in those counties and boroughs; —an innovation which gave rise to the separation into two houses of parliament. Hence the title came by degrees to be confined to the greater barons, or lords of parliament; and, among the peerage, no other barons were admitted except such as had been summoned by writ, in respect of the tenure of their lands or baronies, until Richard II. converted it into a mere title of honour, by conferring it on divers persons by his letters patent.

When a baron is called up to the house of peers by writ of summons, the writ is in the sovereign's name, and he is directed to repair to the parliament appointed to be holden at a certain time and place, and there to treat and advise with his sovereign, the prelates, and nobility, about the weighty affairs of the nation. The ceremony of the admission of a baron into the house of peers is this: He is brought into the house between two barons, who conduct him up to the lord chancellor, his patent or writ of summons being carried by a king-at-arms, and presented by him kneeling to the lord chancellor, who reads it, then congratulates him on his becoming a member of the house of peers, and invests him with his parliamentary robe. Thereafter the patent is delivered to the clerk of parliament, and the oaths are administered to the new peer, who is then conducted to his seat on the barons' bench. The coronation robes of a baron are the same as those of an earl, except that he has only two rows of spots on each shoulder; and, in like manner, his parliamentary robes have but two guards of white fur, with rows of gold lace; but in other respects, they are the same as those of other peers. King Charles II. granted to the barons a coronet, having six large pearls set at equal distances on the chaplet. A baron's cap is the same as a viscount's. His style is *Right Honourable;* and he is addressed by the king or queen, *Right Trusty and Well Beloved.*

Barons by ancient tenure were those who held certain territories of the king, who still reserved the tenure in chief to himself. There were also *barons by temporal tenure*, who held their honours, castles, and manors, as heads of their barony; that is, by grand serjeantry, by which tenure they were anciently summoned to parliament. But at present a baron by tenure is not a lord of parliament till he be called thither by writ. Barons || Baronet.

Barons of the Exchequer, four judges to whom the administration of justice is committed in causes betwixt the king and his subjects relative to matters of revenue. Their office is also to look into the accounts of the king, for which reason they have auditors under them.

Barons of the Cinque-ports were (prior to 1831) members of the house of commons, elected by the cinque-ports, two for each port. These ports are now under the jurisdiction of a *warden*.

Baron and Feme, in *English Law*, a term used for husband and wife, in relation to each other, who are accounted as one person. Hence by the old law of evidence the one party was excluded from being evidence for or against the other in civil questions, and a relic of it is still preserved in the criminal law.

Baron and Feme, in *Heraldry*, is when the coats-of-arms of a man and his wife are borne per pale in the same escutcheon; the man's being always on the dexter side, and the woman's on the sinister. But in this case the woman is supposed not to be an heiress, for then her coat must be borne by the husband on an escutcheon of pretence. See Heraldry.

Baron, or Boyron, *Michel*, a celebrated French actor, born at Paris in 1653; died in 1729. He was first brought on the stage by Moliere, and during his lifetime was said to be "*du théâtre Français l'honneur et la merveille.*" He was equally successful in tragedy and comedy, and likewise composed some comedies. His self-esteem seems to have been equal to his success; "every hundred years," he said, "a Cæsar may be seen, but it needs ten thousand to produce a Baron!"

Baron, *Robert*, an English writer of the seventeenth century, author of a novel called the *Cyprian Academy* (8vo, 1647), and some dramatic pieces, and poems (8vo, 1650).

BARONET, a dignity or degree of honour next below that of baron, and above that of knight, with precedency of all knights excepting those of the Garter.

The dignity of baronet is generally conferred by patent, and forms the lowest degree of honour that is hereditary. The order was instituted by King James I. at the suggestion of Sir Robert Cotton in 1611, when 200 baronets were created at once, being the number to which it was intended they should always be restricted; but it is now enlarged at the sovereign's pleasure, without limitation. Originally the creation of this order seems to have been merely an expedient to raise money in the name of fees, which, in each case, amounted to about L.1200 sterling.

Baronets take precedence according to the dates of their patents, conformably to the terms of which, no intermediate honour between baron and baronets can be established. The title or prefix of *Sir* is granted them by a peculiar clause in their patents, though they be not dubbed knights.

Baronets of Scotland, called also *Baronets of Nova Scotia*. This order of knights-baronets was instituted by Charles I. in the year 1625, when the first person dignified with the title was Sir Robert Gordon of Gordonstone, a younger son of the Earl of Sutherland. The professed object of the institution was to encourage the plantation and settlement of Nova Scotia in North America: hence the king granted to each of them a certain portion of land in that province, which they were to hold of Sir William Alexander, afterwards Earl of Stirling, with precedency to them and their heirs-male for ever, before all knights called *equites aurati*, all lesser barons called *lairds*, and all other gentlemen, except Sir William Alexander, His Majesty's lieutenant in Nova Scotia, his heirs, their wives and chil-

Baronets || Barony.

dren. It was further provided that the title of *Sir* should be prefixed to their Christian name, and *Baronet* added to their surname; and that their own and their eldest sons' wives should enjoy the title of *Lady, Madam*, or *Dame*.

Malone has given the following curious note upon this subject, in his very learned *Life of Dryden*, prefixed to his edition of the prose works of that writer:—"When the order of baronets was first established in 1611, King James engaged that they should not exceed two hundred. However, towards the close of his reign, that number being completed, and the creation of baronets being found a useful engine of government (the courtier by whose influence the title was obtained receiving usually L.1000 for the grant), it was not lightly to be parted with. A scheme, therefore, of creating *Baronets of Scotland* was devised, which, it was conceived, would be no infraction of the original compact, to confine the grants to a limited number; and as the English baronets were created under the great seal of England, for the reduction of Ulster in Ireland, so the Scottish baronets were created under the great seal of Scotland, for the reduction of Acadia, or *Nova Scotia*. The scheme, however, was not carried into execution by King James; but early in the reign of his successor several Scottish baronets were made. From this statement it appears, that there is no more necessity for calling a baronet created under the great seal of Scotland (whether he be an Englishman or Scotchman), a *Baronet of Nova Scotia*, than there is to denominate one created under the great seal of England a *Baronet of Ulster*." (Malone's *Dryden*, vol. i. pp. 28–29.)

Baronets of Ireland. This order was likewise instituted by King James I. in the 18th year of his reign, for the same purpose and with the same privileges within the kingdom of Ireland as had been conferred on the analogous order in England; for which also the Irish baronets paid the same fees into the treasury of Ireland.

BARONI, Leonora, a celebrated singer and composer, was born at Naples, but spent the greater part of her life at Rome. She was daughter of Adriana Baroni of Mantua, baroness of Piancaretta, a lady also distinguished for her musical talents, and, on account of her beauty, surnamed the Fair. A collection of verses in her honour was published in 1623, under the title of *Teatro della gloria D'Adriana*. Leonora, like her mother, was celebrated by the wits; and in 1639 there was published a collection of poems in various languages addressed to her, under the title of *Applausi Poetici alle Glorie della Signora Leonora Baroni*. Among the Latin poems of Milton are no fewer than three, entitled *Ad Leonoram Romæ Canentem*, of which this lady is the subject. Mazuchelli, *Scritt. d'Ital.*; Mangers, *Discours sur la Musique d'Italie*, Paris, 1672.

BARONIUS, Cæsar, a pious and learned cardinal, was born at Sora in 1538. He studied at Rome, and put himself under the discipline of Filippo di Neri, the founder of the congregation of the Oratory; on whose resignation in 1593 Baronius succeeded him as superior. Pope Clement VIII. made him his confessor, and raised him to the rank of cardinal in 1596. He was afterwards made librarian to the Vatican, and died from excessive study in 1607, at the age of sixty-nine. His principal work is his *Annales Ecclesiastici*, from A.D. 1 to 1198, in 12 vols. folio, Rome, 1588–93, which is characterized by very great learning and ability, and has always been in high esteem in the Church of Rome; though, having been composed with the express object of vindicating that church against the supposed misrepresentations of the *Magdeburg Centuriators*, it is necessarily partial and imperfect. The best edition, including the continuation of Raynaldi, is that published at Lucca in 38 vols. folio, 1738–1787. A further continuation in 8 vols. folio, is at present in preparation by Father Theiner, a priest of the Oratory at Rome.

BARONY, Baronia, or *Baronagium*, the lordship or fee of a baron, either temporal or spiritual. Baronies, in their first creation, proceeded from the king himself, the chief lord of the whole realm, and could be holden immediately of no other lord. Thus the king enfeoffed a man of a great seigniory in land, to be held by the person enfeoffed and his heirs, of the king and his heirs, by baronial service; that is, by the service of so many knights as the royal act appointed. In the ages immediately succeeding the Conquest, such seigniory was called a *barony*, but more commonly an *honour*; as the honour of Gloucestershire, of Wallingford, &c. In England these were sometimes called by Norman or other foreign designations, when the same person was lord of an honour in Normandy, or some other foreign country, and also of an honour in England. Thus, William de Forz, de Force, or de Fortibus, was lord of the honour of Albemarle in Normandy, and also of the honours of Holderness and of Skipton in England, and these latter were sometimes called by the Norman name, as the honour of Albemarle, or the honour of the Earl of Albemarle.

Barquicimeto || Barracks.

BARQUICIMETO, a province in Venezuela, with a capital of the same name. This city, which had a population of 15,000, was nearly destroyed by the great earthquake of 1812, which desolated Caraccas; but it has since been rebuilt, and already has above 12,000 inhabitants. Lat. 9. 50. N. Long. 69. 20. W.

BARRA, or Barray, island of. See Barray.

Barra, or Vara, in *Commerce*, a long measure used in Portugal and some parts of Spain, to measure woollen and linen cloths and serges. In Valencia, 13 barras = 12¾ yards English measure; in Castile, 7 barras = 6¾ yards; and in Aragon, 3 barras = 2¾ yards.

BARRACAN, in *Commerce*, a sort of stuff, something like camlet. It is used to make various outer garments. The cities where barracans are chiefly made in France are Valenciennes, Lisle, Abbeville, Amiens, and Rouen.

BARRACKPORE, a town and military cantonment of Hindustan, in the province of Bengal, about 16 miles above Calcutta. The cantonment consists of a large village in the occupation of soldiers, with separate lodges for the European officers. In its vicinity is the country residence of the governor-general of India, situate on the banks of the Hooghly, within a park containing 200 or 300 acres. Lat. 22. 46. Long. 88. 26.

BARRACKS, called by the French *Casernes*, places for soldiers to lodge in, especially in garrisons. Till the middle of the year 1792, when there was a prospect of war with revolutionary France, and the British ministry became apprehensive of disturbances in this country, barracks were not numerous, nor were they under the control and management of a separate and peculiar board. Previous to this they were built under the authority and directions of the Board of Ordnance, which also supplied them with bedding and the necessary utensils; and any extra articles that were requisite were furnished by the secretary at war. In 1792 orders were issued by the ministry for building cavalry barracks with the utmost despatch, and the deputy-adjutant-general was directed to superintend the building and fitting them up. In January 1793 the same officer was appointed superintendent-general of barracks; and on the 1st of May the king's warrant was issued for their regulation. Greater powers were given to the superintendent-general in the year 1794; but as these seemed to interfere with the duties and powers of the Board of Ordnance, a new warrant was issued in the year 1795, defining and limiting the respective duties and powers of the Board of Ordnance, and the superintendent-general, or barrackmaster-general, as he was now called.

In 1806 the barrack establishment was placed under the direction of four commissioners, one of whom was generally a military man. Since 1834 the superintendence of barracks has reverted to the master-general of ordnance

Barracks throughout the country are more immediately

Barramahal || Barratry.

under the management and care of the resident barrack-masters, especially since the reduction of the barrack-office establishment, and the further reduction of the assistant-barrackmasters-general attached to districts.

The barrack districts in Great Britain are—Dover, Eastern, London, Manchester, Medway, Midland and South Wales, Northern, North Britain, South West and Sussex, Woolwich, Exeter, Western, Yorkshire, Guernsey and Alderney, Jersey, Dublin, Athlone, Belfast, Cork, and Limerick.

In the cavalry barracks, field-officers have two rooms each; captains one; subalterns, staff, and quartermasters, one; serjeants of each troop of dragoons, and corporals of each troop of horse, one; eight rank and file one among them; and two rooms are allowed for the officers' mess. In infantry barracks, field-officers are allowed two each; captains one; one is allotted to two subalterns; the staff has one; twelve non-commissioned officers and private men one among them; the serjeant-major and quartermaster-serjeant one; and two are allotted for the officers' mess. The barracks are supplied by the barrack-office with beds, bedding, sheets, blankets, towels, house and stable utensils, coals, and candles; beer was formerly supplied, but now an allowance is made instead of it. Forage is supplied by the commissariat.

The expense of erecting barracks must of course greatly depend on the price of materials at the time, and, in some measure, on the part of the kingdom where they are erected. The total expense incurred by the nation for barracks and the barrack-office, in Great Britain, between the 25th of December 1792 and the 10th of November 1804, was L.9,024,005, 8s. 9d.

During the last war the annual expense of the barrack establishment in Great Britain varied from L.350,000 to L.500,000. But in Ireland, where barracks are more numerous, the expense generally equalled, and often exceeded, that of Great Britain in this particular. Thus, in 1814 the sum required for Great Britain was L.309,826, whilst that necessary for Ireland was L.360,515; and a similar excess appears in the peace estimate for 1816, which was for Great Britain L.173,500, and for Ireland L.213,000. Since this period the annual expense has of course been greatly reduced.

BARRAMAHAL, a territorial subdivision in the south of Hindustan, situated between the 12th and 13th degrees of N. Lat. This district was annexed by Hyder to the dominions of Mysore about the middle of the last century; in 1792 it was ceded to the British government by the treaty of Seringapatam, and now constitutes the northern portion of the British district of Salem.

BARRAS, Paul Jean François Nicolas, Comte de, the representative of an ancient family in Provence, a leader in the first French Revolution, and member of the executive directory, was born in Provence in 1755, and died near Paris in 1829. See France.

BARRATOR, or Barretor, in the law of England, a person guilty of barretry. See Barretry.

Lambert conceives the word *barretor* to have been formed from the Latin *balatro*, a vile knave; but the proper derivation is from the French *barrateur*, a deceiver; and this agrees with the description of a common barretor given by Lord Coke, namely, that he is a common mover and maintainer of suits in disturbance of the peace, particularly by taking and detaining the possession of houses and lands or goods by false inventions or pretences. Hence it is said that a common barretor is the most dangerous oppressor in the law, for he oppresses the innocent under colour of law, which was made to protect them from oppression.

BARRATRY, in a shipmaster, consists in defrauding the owners. If goods delivered on shipboard are embezzled, all the mariners are bound by the maritime law to contribute to the satisfaction of the party that has lost his goods; and the cause is to be tried in the admiralty. In a case where a ship had been insured against the barratry of the master, and the jury found that the ship was lost by the fraud and negligence of the master, the court ruled that the fraud was barratry, though not named in the covenant, but that negligence did not amount to that offence. A shipmaster who is at the same time a part owner, cannot commit barratry. See Marshall on *Insurance*, I. c. 12; Park on *Insurance*, c. 5.

Barraux || Barrère.

BARRAUX, a fortress of Dauphiné, now in the department of Isère. It stands on the river Isère, in the valley of Grésivaudan, and was built in 1597.

BARRAY, or Barra, (from the Scandinavian, *Baraey*, isle of the ocean,) one of the Hebrides or Western Isles of Scotland, forming part of Inverness-shire. It lies about 5 miles S.W. of South Uist, and is 8 miles in length by from 2 to 4 miles in breadth. The parish of the same name comprehends, besides Barra, a number of smaller islands and islets, and is estimated to contain 4000 acres of arable, and 18,000 of meadow and hill pasture. The cod, ling, and herring fisheries are considerable; and its coasts abound with shell-fish, especially cockles. On Barra Head, the highest part of Bernera, one of the Barra Islands, is a lighthouse with an intermitting light 680 feet above high-water, in Lat. 56. 48. N., Long. 7. 38. W. Population of island (chiefly Roman Catholics), in 1841, 1977; in 1851, 1624.

BARRE, Louis François Joseph de la, a learned French historian and antiquary, born at Tournay in 1688. Besides various learned papers contributed to the *Memoirs of the Academy of Inscriptions and Belles-Lettres*, of which he was a member, he published, in 1729, *Mémoires pour servir à l'Histoire de France et de Bourgogne*. He also contributed many articles to the edition of Moreri's Dictionary published in 1724, and was concerned in various other works. He died in 1738, whilst preparing a dictionary of Greek and Roman antiquities.

BARREL, in *Commerce*, a round vessel bulging in the middle, composed of staves, and bound with hoops. It is chiefly used for holding liquids, particularly ale and beer. The barrel of beer in London formerly contained only 32 ale gallons, $= 32\frac{1}{2}$ imperial gallons; but by 43d Geo. III. cap. 69, it was enacted that the barrel of beer should contain 36 gallons, and by 6th Geo. IV. cap. 58, the standard *imperial* gallon is always to be understood in any excise law where the gallon is mentioned. The barrel therefore contains 36 imperial gallons. (M'Culloch's *Dict. of Commerce.*)

Barrel also denotes a certain weight of several kinds of merchandise, and differs according to the nature of the commodities. Thus a barrel of Essex butter weighs 106 pounds, and of Suffolk butter 256 pounds; a barrel of herrings ought to contain 32 gallons wine-measure, and about 1000 herrings; a barrel of salmon should contain 42 gallons, and a barrel of eels the same; a barrel of soap should weigh 256 lb. The measure of capacity called barrel-bulk = 5 cubic feet.

Barrel, in *Mechanics*, a term given by watch-makers to the cylinder about which the spring is coiled; and by gunsmiths to the cylindrical tube of a gun, pistol, or blunderbuss, which contains the charge.

Barrel, in *Anatomy*, the cavity of the *tympanum*.

BARREN CAPE, an island in Bass's Straits, in the South Pacific Ocean, between Great Island on the N. and Clarke's Island on the S. It is about twenty miles in length by ten in breadth, and chiefly covered with low vegetation. Long. 148. 10. E. Lat. 40. 23. S.

BARREN ISLAND, an island in the Bay of Bengal, about 18 miles in circumference. It contains a volcano 1800 feet above the level of the sea, which is sometimes in a state of activity, and discharges immense columns of smoke and showers of red-hot stones. Long. 94. 1. E. Lat. 12. 15. N.

BARRÈRE (or BARÈRE) DE VIEUZAC, Bertrand, originally an *avocat*, was one of the most noted and

Barretry || Barrington.

cruel members of the convention in the first French Revolution. He was born at Tarbes in 1755, and died at Paris in 1841. His was the horrible apophthegm, "*Il n'y a que les morts qui ne reviennent pas.*" The list of his works, historical, political, poetical, and miscellaneous, is numerous. The graceful style in which he couched even his sanguinary proscriptions procured him the singular title of *the Anacreon of the Guillotine.* See FRANCE.

BARRETRY, or BARRATRY, in the *Law of England*, is, according to Blackstone, "the offence of frequently exciting and stirring up suits and quarrels between the lieges, either at law or otherwise. The punishment for this offence, in a common person, is by fine and imprisonment; but if the offender, as is too frequently the case, belongs to the profession of the law, a barretor who is thus able as well as willing to do mischief ought also to be disabled from practising for the future." And hence it is enacted by statute 12th Geo. I. cap. 29, which is made perpetual by the 21st Geo. II. cap 3, "that if any person who has been convicted of common barretry, shall act or practise as an attorney, solicitor, or agent, in any suit or action, the court, upon complaint, shall examine the matter in a summary way, in open court, and, if proved, shall direct the offender to be transported for seven years." "To this head," continues the learned commentator, "also may be referred an offence of equal malignity and audaciousness, that of suing another in the name of a fictitious plaintiff, either one not in being at all, or one who is ignorant of the suit. This offence, if committed in any of the king's superior courts, is left, as a high contempt, to be punished at their discretion; but in courts of a lower degree, where the crime is equally pernicious, but the authority of the judges is not equally extensive, it is directed by statute 8th Elizabeth, cap. 2, to be punished by six months' imprisonment, and treble damages to the party injured."

In Scotland the crime of a judge who receives a bribe is called barratry.

BARRHEAD, a large village of Scotland, county of Renfrew, three miles S. of Paisley, and 8 miles S.W. of Glasgow. Its population, which in 1841 was 3492, had increased in 1851 to 6069. The principal employment is spinning, weaving, and bleaching. It is connected with Glasgow by the Glasgow Barrhead and Neilston Railway.

BARRICADE, or BARRICADO, a military term for a fence formed in haste with trees, baskets of earth, palisades, waggons, or any bulky material, to serve as a defence against the shot or assault of the enemy.

BARRICADE, in *Naval Architecture*, a strong wooden rail, supported by stanchions, extending across the foremost part of the quarterdeck in ships of war. The vacant spaces between the stanchions are commonly filled with rope-mats, cork, or pieces of old cable; and the upper part, which contains a double rope-netting above the rail, is stuffed with hammocks, to prevent the execution of small-shot in time of action.

BARRIER, in *Fortification*, a kind of fence erected at a passage, retrenchment, or breach, composed of great stakes, about four or five feet in height, placed at the distance of eight or ten feet spart, with transoms or overthwart rafters, to stop the enemy.

It is also applied to a wall of defence, fortress, or fortified town, on the frontier of a country.

BARRINGTON, The HON. DAINES, fourth son of Lord Viscount Barrington, a distinguished antiquary and naturalist, born about the year 1730. He was educated for the profession of the law, and, after filling various posts, was appointed a Welsh judge in 1757, and afterwards second justice of Chester. He never rose to much eminence at the bar, but he showed his knowledge of the law as a subject of liberal study by a valuable publication entitled *Observations on the Statutes, chiefly the more ancient, from Magna Charta to 21st James I. cap. 27, with an Appendix, being a proposal for new-modelling the Statutes*, 1766, 4to; a work which has been quoted with merited commendation by many of our historians and constitutional antiquaries. In 1773 he published an edition of Orosius, with Alfred's Saxon version, and an English translation with notes of his own, which was severely animadverted on by the critics. His *Tracts on the Probability of reaching the North Pole*, 1775, 4to, were written in consequence of the northern voyage of discovery undertaken by Captain Phipps, afterwards Lord Mulgrave. In these he has accumulated a variety of evidence favourable to his own opinion of the practicability of attaining the object in which that voyage had failed; and it is not improbable that his views and arguments had some effect in determining the government at a later period to renew the attempt. Mr Barrington's other writings are chiefly to be found in the publications of the Royal and Antiquarian Societies, of both of which he was long an assiduous member, and of the latter vice-president. Many of these were collected by him in a quarto volume entitled *Miscellanies on various Subjects*, 1781. Among the most curious and ingenious of his papers, are his *Experiments and Observations on the Singing of Birds*, and his *Essay on the Language of Birds.* He died on the 14th March 1800, and was buried in the Temple church.

Barrington.

BARRINGTON, *John Shute*, Lord Viscount Barrington, a nobleman distinguished for theological learning, was the youngest son of Benjamin Shute, merchant, and was born at Theobald, in Hertfordshire, in 1678. He received part of his education at the university of Utrecht; and, after returning to England, studied law in the Inner Temple. In 1701 he published several pamphlets in favour of the civil rights of Protestant dissenters, to which body he belonged. On the recommendation of Lord Somers, he was employed to engage the Presbyterians in Scotland to favour the union of the two kingdoms; and, in 1708, he was rewarded for this service by being appointed to the office of commissioner of the customs. From this, however, he was removed on the change of administration in 1711; but his fortune had, in the meantime, been improved by the bequest of two considerable estates; one of them left him by Francis Barrington of Tofts, Esq., whose name he assumed by act of parliament; the other by John Wildman of Becket, Esq. Mr Barrington now stood at the head of the dissenters. On the accession of George I. he was returned member of parliament for Berwick-upon-Tweed; and in 1720 the king raised him to the Irish peerage, by the style and title of Viscount Barrington of Ardglass. But having unfortunately engaged in one of the bubbles of the time, the Harburg lottery, he incurred the disgrace of expulsion from the House of Commons in 1723; a punishment which was thought greatly too severe, indeed altogether unmerited on his part. In 1725 he published his principal work, entitled *Miscellanea Sacra, or a New Method of considering so much of the History of the Apostles as is contained in Scripture, in an Abstract of their History, an Abstract of that Abstract, and four Critical Essays*, 2 vols. 8vo; afterwards reprinted with additions and corrections, in 3 vols. 8vo, 1770, by his son, the Bishop of Durham. In the same year he published *An Essay on the several Dispensations of God to Mankind.* He was the author of various other tracts, chiefly on subjects relating to religious toleration. He died in 1734, leaving a number of children, five of whom rose to high stations in the church, the law, the army, and the navy Lord Barrington was a friend and disciple of Locke, whose sentiments he adopted as to the right and advantage of free inquiry, and the value of civil and religious liberty; and he contributed greatly to the rising spirit of liberal scriptural criticism amongst those who wished to render religion a subject of rational belief. He was a man of great moderation, and, though chiefly connected with the dissenters, he occasionally communicated with the Established church.

Barrister || Barrow.

BARRISTER is a counsellor learned in the law, admitted to plead at the bar, and there to take upon him the protection and defence of clients. "Barristers," observes Mr Justice Blackstone, "are in our old books styled apprentices (*apprenticii ad legem*), being looked upon as merely learners, and not qualified to execute the full office of an advocate till they were sixteen years' standing; at which time, according to Fortescue, they might be called to the state and degree of serjeants, or *servientes ad legem*." According to Dugdale, they seem to have been first appointed by an ordinance in parliament of 20th Edward I.

The rank or degree of barrister-at-law is conferred exclusively by the inns of court, and its possession constitutes an indispensable qualification for practising as an advocate in the superior courts at Westminster.

In order to be entitled to be called to the bar, it is necessary for the student to have kept commons for three years, that is, twelve terms, by dining in the hall of the society of which he is entered, three times at least in each term. The usual course is to attend as a student in the chambers of a practising barrister, conveyancer, or special pleader, in order to attain a knowledge of the practice and of the principles of the law. Under the new regulations of Hilary term 1853, no student is eligible to be called to the bar who shall not have satisfactorily passed a public examination, *or* have attended during one whole year the lectures of two of the readers appointed on—1. Constitutional Law and Legal History; 2. Equity; 3. Jurisprudence and the Civil Law; 4. The Law of Real Property; and 5. The Common Law of England. The Council of Legal Education have also instituted a public examination of candidates for honours or certificates, entitling students to be called to the bar two terms before the regular period; and such students rank in seniority over all other students called on the same day.

In accordance with the notion derived from the ancient Roman orators or patrons, who practised *gratis* for honour or to gain influence, the fees of counsel are given, not as *locatio vel conductio*, but as *quiddam honorarium*, and hence no action can be maintained for their amount.

Counsel is not answerable for any matter spoken by him relating to the cause in hand and suggested in his instructions, even though it prove untrue and reflect on another's reputation; but it is otherwise if the matter be not pertinent; and under the statute of Westm. 1 (3d Edward I. cap. 28) they are punishable with imprisonment for a year and a day, and perpetual silence in the courts, if guilty of deceit or collusion; or they may for gross misconduct be disbarred by the benchers of their inn of court. See ADVOCATE. (R. M—M.)

BARRITUS, or more properly *Barītus* (from the old German *bar*, *baren*, to raise the voice), was the war-cry of the Germans, and adopted by the Romans to signify the general shout raised by their armies on their first encounter, after the *classicum* or alarm.

BARROS, JOAO DE, a celebrated Portuguese historian, born about 1496; died in 1570. In 1522, he was made governor of St George del Mina, on the coast of Guinea. Three years after, the king recalled him to court, and made him treasurer of the Indies. This appointment inspired him with the thought of writing the well-known and valuable history entitled *Azia Portuguesa;* the first decade of which he published in 1552, the second in 1553, and the third in 1563; the fourth was not published till 1615. Several authors have continued the work, so that it extends to twelve decades. A handsome edition of the original work, and its continuations, was published at Lisbon in 1774, in 11 vols. 8vo.

BARROW, an artificial hillock or mound, used in ancient times as a repository for the dead. They were formed either of stones heaped up, or of earth. The former, more generally known by the name of *cairns*, are almost exclusively confined to Scotland. Of the latter, Dr Plott takes notice of two sorts in Oxfordshire; one placed on the military ways, the other in the fields or woods; the first sort being probably of Roman origin, the other erected by the Britons or Danes. Monuments of this kind are also very frequent in Scotland. On digging into barrows, urns made of calcined earth, and containing burnt bones and ashes, have sometimes been found; in others are found stone chests, containing bones entire; in others, again, bones neither lodged in chests nor deposited in urns. These tumuli are round, not greatly elevated, and generally at their bases surrounded by a fosse. They are of different sizes, being in proportion, it is supposed, to the rank and power of the deceased person. Of those found in the Orkneys, some are formed of earth alone, whilst others consist of stone covered with earth. In one of the former was discovered a coffin made of six flat stones, but too short to receive a body at full length. The latter feature is a general characteristic of all these sarcophagi: the skeletons found in them lie with the knees pressed to the breast, and the legs doubled along the thighs. In one of them were found multitudes of small beetles; and as similar insects have been discovered in the bag which inclosed the sacred ibis among the Egyptians, we may suppose that the nation to whom these tumuli belonged had the same superstition respecting them as the subjects of the Pharaohs. Ancient Greece and Latium concurred with the natives of this island in the erection of sepulchral tumuli. Patroclus among the Greeks, and Hector among the Trojans, received the same funeral honours with our Caledonian heroes; and the ashes of Dercennus the Laurentine monarch could boast of no prouder receptacle. The urn and pall of the Trojan warrior might perhaps be more superb than those of a British leader; but the monument of each was composed of the same rude materials, dug from the bosom of the earth. The Grecian barrows, however, do not seem to have been all equally simple. The barrow of Alyattes, father of Crœsus king of Lydia, is described by Herodotus (i. 93.) as a most superb monument, inferior only to the works of the Egyptians and Babylonians. It was a vast mound of earth nearly a mile in circumference, heaped on a basement of large stones, by three classes of the people, one of which was composed of girls devoted to prostitution. Alyattes died in the year B.C. 560; but Herodotus informs us, that, in his time, above a century afterwards, five stones, or *stelæ*, on which letters were engraved, remained on the top, recording what each class had performed; and from the measurement it appeared that the greater portion of the work had been done by females. It was customary among the Greeks to place on barrows the image of some animal, or round pillars (*stelæ*), with inscriptions. The famous barrow of the Athenians in the plain of Marathon, described by Pausanias, is an instance of the latter usage. An ancient monument in Italy near the Appian Way, vulgarly called the sepulchre of the Curiatii, has the same number of *termini* as the barrow of Alyattes; the basement, which is square, supporting five round pyramids.

Barrow.

Barrows, and similar tumuli, are also found in great numbers in America. These are of different sizes; some of them being constructed of earth, and others of loose stones. That they were repositories of the dead has been generally believed; but on what particular occasions they were constructed is matter of conjecture. Some have thought that they covered the bones of those who had fallen in battle on the spot; others ascribe them to the custom said to prevail among the Indians, of collecting at certain periods the bones of all their dead, wheresoever deposited at the time of death; whilst others, again, suppose them to have been the general sepulchre for towns that existed on or near the spots where they are met with. For a minute and interesting account of one of these remarkable tumuli, the reader may consult Mr Jefferson's *Notes on the State of Virginia*, p. 156. See also Wörsae's *Scandinavian Antiquities*; and Hamilton's *Researches in Asia Minor*, vol. i.

Barrow. BARROW, a large river of Ireland, which rises in Queen's county, and being joined by the Nore and the Suir, falls into the sea at Waterford Bay. In spring-tides, vessels of 300 tons can ascend to New Ross, and it is navigable for barges to Athy, where it is joined by a branch of the Grand Canal.

BARROW, *Isaac*, an eminent mathematician and divine, was the son of Mr Thomas Barrow, a linen-draper in London, where he was born in 1630. He was at first placed for two or three years at the Charter-house School. There, however, his conduct gave but little hopes of his ever succeeding as a scholar; for he was extremely fond of fighting, and of promoting pugnacity among his school-fellows. But being removed from this establishment, his disposition took a happier turn; and having soon made considerable progress in learning, he was admitted a pensioner of St Peter's College, and afterwards of Trinity College, Cambridge, where he applied himself with great diligence to the study of literature and science, especially of natural philosophy. He afterwards turned his thoughts to the profession of physic, and made some progress in anatomy, botany, and chemistry; after which he studied chronology, geometry, and astronomy. He then travelled into France and Italy, and in a voyage from Leghorn to Smyrna gave proofs of great personal bravery; for the ship having been attacked by an Algerine pirate, Barrow remained upon deck, and fought with the utmost intrepidity, until the pirate, unprepared for the stout resistance made by the ship, sheered off and left her to pursue her voyage.

At Smyrna he met with a most kind reception from Mr Bretton, the English consul, upon whose death he afterwards wrote a Latin elegy. From this place he proceeded to Constantinople, where he received similar civilities from Sir Thomas Bendish, the English ambassador, and Sir Jonathan Dawes, with whom he afterwards contracted an intimate friendship. While at Constantinople he read and studied the works of Chrysostom, once bishop of that see, whom he preferred to all the other fathers. He resided in Turkey somewhat more than a year, after which he proceeded to Venice, and thence returned home through Germany and Holland in 1659. Immediately on his return he received episcopal ordination from Bishop Brownrig; and in 1660 he was appointed to the Greek professorship at Cambridge. When he entered upon this office, he intended to have prelected upon the tragedies of Sophocles; but he altered his intention, and made choice of Aristotle's Rhetoric. His lectures on this subject, however, having been lent to a friend who never returned them, are irrecoverably lost. In July 1662 he was elected professor of geometry in Gresham College, on the recommendation of Dr Wilkins, master of Trinity College, and afterwards bishop of Chester; and in May 1663 he was chosen a fellow of the Royal Society, at the first election made by the council after obtaining their charter. The same year the executors of Mr Lucas, who, according to the will of that individual, had founded a mathematical chair at Cambridge, fixed upon Barrow as the first professor; and although his two professorships were not inconsistent with each other, he chose to resign that of Gresham College, which he did on the 20th May 1664. In 1669 he resigned his mathematical chair to his illustrious friend Isaac Newton, having now determined to renounce the study of mathematics for that of divinity. Upon quitting his professorship, Barrow was only a fellow of Trinity College; but his uncle gave him a small sinecure in Wales, and Dr Seth Ward, bishop of Salisbury, constituted him a prebend in that church. In the year 1670 he was created doctor in divinity by mandate; and, upon the promotion of Dr Pearson, master of Trinity College, to the see of Chester, he was appointed to succeed him by the king's patent, bearing date the 13th February 1672. When the king advanced Barrow to this dignity, he was pleased to say, "he had given it to the best scholar in England." His Majesty did not speak from report, but from his own knowledge; for the doctor being then his chaplain, His Majesty frequently conversed with him, and in his humorous way used to call him an "unfair preacher," as he exhausted every subject he discussed, and left no room for others to come after him. In 1675 Dr Barrow was chosen vice-chancellor of the university. His scientific works are very numerous, and such as do honour to the science and literature of his country. They are, 1. Euclid's Elements; 2. Euclid's Data; 3. Optical Lectures, read in the public school of Cambridge; 4. Thirteen Geometrical Lectures; 5. The Works of Archimedes, the four Books of Apollonius's Conic Sections, and Theodosius's Spherics explained in a New Method; 6. A Lecture, in which Archimedes's Theorems of the Sphere and Cylinder are investigated and briefly demonstrated; 7. Mathematical Lectures, read in the public schools of the university of Cambridge. The above were all written in Latin. His English works have been collected and printed together in four volumes folio. "The name of Dr Barrow," says Grainger, "will ever be illustrious for a strength of mind and a compass of knowledge that did honour to his country. He was unrivalled in mathematical learning, and especially in the sublime geometry; in which he has been excelled only by one man, and that man was his pupil, the great Sir Isaac Newton. The same genius that seemed to be born only to bring hidden truths to light, to rise to the heights or descend to the depths of science, would sometimes amuse itself in the flowery paths of poetry; and he composed verses both in Greek and Latin. He at length gave himself up entirely to divinity; and particularly to the most useful part of it, that which has a tendency to make men wiser and better. He has, in his excellent sermons on the Creed, solved every difficulty and removed every obstacle that opposed itself to our faith, and made divine revelation as clear as the demonstrations in his own Euclid. In his sermons he knew not how to leave off writing till he had exhausted his subject; and his admirable discourse on the duty and reward of bounty to the poor took him up three hours and a half in preaching." This great man, who was a bright example of Christian virtue, as well as a prodigy of learning, died on the 4th of May 1677, in the forty-seventh year of his age; and was interred in Westminster Abbey, where a monument, surmounted with his bust, was soon after erected, by the contributions of his friends.

Barrow. BARROW, *Sir John, Bart., F.R.S., LL.D.*, was born near Ulverston, in Lancashire, June 19. 1764. His early opportunities of instruction were limited; but by self-education he matured those powers which eventually were turned to so good an account. He displayed, at an early age, a decided inclination for mathematical pursuits. Some of his earlier years were passed as superintending clerk of an iron foundry at Liverpool; and he afterwards taught mathematics at an academy in Greenwich. While in this latter situation he was fortunate in obtaining, through the interest of Sir George Staunton, a place in the first British embassy to China. He was thus enabled to put his foot on the first step of the ladder of ambition; but each step in his subsequent career may be fairly said to have been achieved by himself. The account of the embassy, published by Sir George Staunton, records many of Mr Barrow's valuable contributions to literature and science connected with China. This work, together with his own subsequently published volume of travels, is ample evidence how well his time had been employed. Few persons could within the space of a few months overcome all the practical difficulties of such a language as the Chinese; but Mr Barrow soon began to converse in it, and acquired a complete knowledge of its theory. His papers on this subject in the *Quarterly Review* (to which periodical he was for many years a very frequent contributor) contain the best and most popular account of that singular language ever presented to the British public.

Barrow's Straits.

Although Mr Barrow ceased to be personally connected with our affairs in China after the return of the embassy in 1794, he always continued to take a lively interest in the varying circumstances of our relations with that empire. On the occasion of the second embassy under Lord Amherst in 1816, he was of course consulted by the ruling powers; but unfortunately his advice was not taken; and in consequence of the injudicious rejection of the proposal which he had suggested for getting rid of the vexatious question of the Chinese ceremony, Lord Amherst and his colleagues were compelled to abandon the personal reception of the mission for the sake of preserving the honour and interests of the English in China, which would have been essentially damaged by the acceptance of the terms upon which it was offered. Mr Barrow was likewise consulted on the occasion of our recent conflict with China, which, it is to be hoped, has secured our future peace with that country.

Lord Macartney was naturally anxious to secure the aid of such a man as Mr Barrow in his next public service, his important and delicate mission to settle the government of our newly-acquired colony of the Cape of Good Hope. Mr Barrow was intrusted with our first communication with the Caffre tribes; and it would have been well if the spirit, judgment, and humanity, which he then displayed had more uniformly governed our subsequent transactions with that remarkable race. The two volumes of his history of the colony made the public at once fully acquainted with the extent, capacities, and resources of that important, but till then little understood, acquisition of the British crown.

There is little doubt that it was the perusal of this valuable work which mainly decided Lord Melville to accept Lord Macartney's recommendation of a perfect stranger to him, as Mr Barrow then was, as his second secretary of the admiralty. Mr Barrow's subsequent career for forty years at the admiralty, embracing the whole period of the last war, will be for ever historically associated with the civil administration of our navy for the same period. He enjoyed the uniform esteem and confidence of the eleven chief lords who successively presided at the admiralty board during that period, and more especially of King William IV., while lord high admiral, who honoured him with tokens of his personal regard. Mr Barrow received the honour of the baronetcy during the short administration of Sir Robert Peel in 1835; and the information was communicated to him by Sir Robert in a letter acknowledging, in highly gratifying terms, his literary and scientific eminence, and his "long, most able, and most faithful public service."

Sir John Barrow, besides the works already mentioned, published the lives of Lord Macartney, Lord Anson, Lord Howe, and Peter the Great; and he was also the author of several valuable contributions to the seventh edition of the Encyclopædia Britannica.

Sir John retired from public life in 1845, in consideration of his advanced years, although still in vigorous possession of all the mental and bodily powers required for the due discharge of the functions of his office. In the course of the succeeding three years his vital energies gradually declined, but he nevertheless continued so fully in the enjoyment of his faculties, writing a history of the modern arctic voyages of discovery, of which he was a great promoter, as well as his autobiography, that his friends and relatives entertained no apprehension that his end was so near. He expired suddenly on the 23d November 1848, in the 85th year of his age, much honoured and respected by his friends and the public at large.

BARROW'S STRAITS, a channel leading from the N.W. part of Baffin's Bay into the Polar Sea, and lying between Lat. 73. 45. and 74. 40. N. It is about 200 miles in length, and has an average breadth of 60 or 70 miles. The coasts on both sides are generally steep and rugged, with numerous bays and inlets. In many places it is upwards of 200 fathoms in depth, and not unfrequently no bottom can be found. It abounds in whales and other inhabitants of the northern seas.

Barry.

BARRY, or BARRI, GIRALD DE, commonly called *Giraldus Cambrensis*, an historian and ecclesiastic of the twelfth and thirteenth century, was born at the castle of Mainarpir, near Pembroke, in 1146. By his mother he was descended from the princes of South Wales; and his father, William de Barri, was one of the chief men of that principality. Being a younger brother, and intended for the church, he was sent to St David's, and educated in the family of his uncle, the bishop of that see. When about twenty years of age he was sent to the university of Paris, where he continued for three years, and, according to his own account, became an excellent rhetorician. On his return he entered into holy orders, and obtained several benefices both in England and Wales. But observing with much concern that his countrymen the Welsh were very backward in paying tithes of wool and cheese, he applied to Richard, archbishop of Canterbury, and was appointed his legate in Wales for rectifying this and other disorders. Barri excommunicated all, without distinction, who refused to compound matters with the church, and, in particular, delivered over bodily to the Evil One those who withheld the tithes. Not satisfied with enriching, he also attempted to reform, the clergy. He delated the archdeacon of Brecon to the archbishop, for the unpardonable crime of matrimony; and on his refusing to put away his wife, he was deprived of his archdeaconry, which was bestowed upon the zealous legate. On the death of his uncle, the bishop of St David's, in 1176, he was elected his successor by the chapter; but this choice having been made without the permission of Henry II., Girald prudently declined to insist upon it, and went again to Paris to prosecute his studies. He speaks with exultation of the prodigious fame which he acquired by his eloquent declamations in the schools, and of the crowded audiences who attended them. Having spent about four years at Paris, he returned to St David's, where he found everything in confusion; and on the expulsion of the bishop by the people, which took place soon after, he was appointed administrator by the archbishop of Canterbury, and governed the diocese in that capacity till 1184, when the bishop was restored. About the same time he was called to court by Henry II., appointed one of his chaplains, and sent into Ireland with Prince John, by whom he was offered the united bishoprics of Fernes and Leighlin, but declined them, and employed his time in collecting materials for his Topography of Ireland, and his history of the conquest of that island, which was completed in three books in 1187. In 1188 he attended Baldwin, archbishop of Canterbury, in his progress through Wales, preaching a crusade for the recovery of the Holy Land; an employment in which he tells us, with his usual modesty, that he was far more successful than the primate,—adding significantly, that the people were most affected with the Latin sermons (which they did not understand), melting into tears, and coming in crowds to take the cross. On the accession of Richard I. in 1189, he was sent by that prince into Wales to preserve the peace of the country, and was even joined in commission with William Longchamp, bishop of Ely, as one of the regents of the kingdom. He failed, however, to improve this favourable opportunity; and having fixed his heart on the see of St David's, the bishop of which was very old and infirm, he refused the bishopric of Bangor in 1190, and that of Landaff the year following. But in 1192 the state of public affairs became so unfavourable to Barri's interest at court that he determined to retire. He proceeded to Lincoln, where William de Monte read lectures in theology with great applause; and here he spent about six years in the study of divinity, and in composing several works. At

Barry. last the see of St David's, which had long been the object of his ambition, became vacant, and he was unanimously elected by the chapter, but met with so powerful an adversary in Hubert, archbishop of Canterbury, that it involved him in a litigation which lasted five years, cost him three journeys to Rome, and ended in his defeat in the year 1203. Retiring from the world, he spent the last seventeen years of his life in a studious privacy, composing many books, of which a catalogue is given in the *Biographia Britannica*. His MSS. are preserved in the British Museum, the library at Lambeth, and the Bodleian Library. Of his published works, the best known is his *Itinerarium Cambriæ*, of which a translation, illustrated with annotations, and accompanied with a life of the author, was published by Sir Richard Colt Hoare, in two splendid quarto volumes, in 1806.

BARRY, *James*, an eminent painter, was born at Cork, on the 11th October 1741. His father had been a builder, and at one time of his life a coasting trader between the two countries of England and Ireland. To this business of trader was James destined, and he actually made, when a boy, several voyages; but these voyages being forced upon him, he on one occasion ran away from the ship, and on others discovered such an aversion to the life and habits of a sailor, as to induce his father to relinquish all hopes of him in this line, and to suffer him to pursue his inclinations, which led him to drawing and study. When on board his father's vessel, instead of handling sails and ropes, and climbing the mast, he was generally occupied with a piece of black chalk, sketching the coast or drawing figures, as his fancy directed him. When his father found that the idea of making a sailor of him must be given up, he permitted him to acquire as much instruction as the schools of Cork afforded, but long retained his aversion to the chalk drawings with which the floors and walls of the house were covered; the boy being always engaged in some attempt at large figures, and early catching at the means of representing action, attitude, and passion. It was at a very early period of his life that young Barry offered to furnish the drawings, and, as it is believed, helped to etch the engravings, such as they were, for a set of fables or emblems which a bookseller in Ireland had undertaken to reprint. At the schools in Cork to which he was sent, he was distinguished by his parts and industry above his school-fellows; his habits differed from those of ordinary boys, as he seldom mixed in their games or amusements, but at those times stole off to his own room, where he worked at his pencil, or was studying some book that he had borrowed or bought. He would spend whole nights in this manner at his studies, to the alarm of his mother, who dreaded his injuring his health or setting fire to the house, and who often kept up his sister or the servant to watch him. His allowance of money he spent in buying books or candles to read by; he sometimes locked himself up in his room for days, and seldom slept upon his bed, or else made it so hard as to take away the temptation or luxury of lying long in it. It is not to be understood that at this period he used to lead the life of an absolute recluse, for he could and did occasionally join in any feats going on in the neighbourhood, and was not behind other boys in such pastimes and mischief as boys are usually fond of. An adventure which happened to him about this time, and which left a strong impression on his mind, is worth mentioning here. In one of his rambles in the neighbourhood, he entered, one winter's evening, an old, and, as he thought, an uninhabited house, situate in a narrow by-lane in the city of Cork. The house was without doors or windows; but curiosity impelled him to enter, and, after mounting a rotten staircase which conducted to empty rooms on different floors, he arrived at the garret, where he could just discern, by the glimmering light of a few embers, two old and emaciated figures, broken by age, disease, and want, sitting opposite each other, in the act, as far as their palsied efforts would permit, of tearing each other's faces; not a word being uttered by either, but with the most horrible grimaces that malice could invent. They took no notice of his entrance, but went on with their deeds of mutual hate; which made such an impression on the boy that he ran down stairs, making his own reflections, which he afterwards found verified through life, that man and all animals are malicious and cruel in proportion as they are impotent; and that age and poverty, two of the worst evils in human life, almost always add to the calamities inherent in them by arts of their own creating. As his industry was excessive, his advances in the acquisition of knowledge were rapid, and he was regarded as a prodigy by his school-fellows. His mother being a zealous Catholic, the son could not avoid mixing at times in the company of priests resident at Cork, who pointed out to him books of polemical divinity, of which he became a great reader, and for which he retained a strong bias during his lifetime. He was said at one time to have been destined for the priesthood, but for this report there is no authority. He, however, always continued a Catholic, and in the decline of life manifested rather a bigoted attachment to the religion of his youth. Barry.

About the age of seventeen he first attempted oil painting, and between that and the age of twenty-two, when he first went to Dublin, he produced several large pictures, which decorated his father's house, and represented subjects not often handled by young men, such as Æneas escaping with his family from the flames of Troy, Susanna and the Elders, Daniel in the Lion's Den, &c. At this period he also produced the picture which first drew him into public notice, and gained him the acquaintance and patronage of the celebrated Edmund Burke. This picture was founded on an old tradition of the landing of St Patrick on the sea-coast of Cashel, and of the conversion and baptism of the king of that district by the patron saint of Ireland. Barry's manner of treating it was such as to insure him the applause and admiration of the connoisseurs of the metropolis of the sister kingdom, where it was exhibited in 1762 or 1763. He took this picture with him to Dublin; and when he went to the exhibition room, being delighted with the encomiums it received from the spectators, he could not refrain from making himself known as the painter. His pretensions were treated with incredulous contempt by the company, and Barry burst into tears of anger and vexation. During his early acquaintance with Burke, having fallen into a dispute on the subject of taste, he quoted a passage in support of his opinion from the *Essay on the Sublime and Beautiful*, which had been just then published anonymously, and which Barry, in his youthful admiration of it, had, it seems, transcribed entire. Burke affected to treat this work as a theoretical romance of no authority whatever; which threw Barry into such a rage in its defence, that Mr Burke thought it necessary to appease him by owning himself to be the author. The scene ended in Barry's running to embrace him, and showing him the copy of the work which he had been at the pains to transcribe. After a residence of seven or eight months in Dublin, an opportunity offered of accompanying some part of Mr Burke's family to London, which he eagerly embraced. This took place some time in the year 1764, when he was twenty-three years of age, and with one of those advantages which but rarely fall to the lot of young artists on their arrival in the British capital, that of being recommended to the acquaintance of the most eminent men in the profession by the persuasive eloquence of a man who, to genius in himself, added the rare and noble quality of encouraging it in others.

By the liberality of Mr Burke and his other friends, Mr Barry, in the latter part of 1765, was enabled to proceed to the Continent, where he remained till the beginning of 1771, studying his art with an enthusiasm which seemed to augur the highest success, and making observations on the different *chefs d'œuvre* of Italy with equal independence of

Barry. judgment and nicety of discrimination. He proceeded first to Paris, then to Rome, where he remained upwards of three years, from thence to Florence and Bologna, and home through Venice. His letters to the Burkes, giving an account of Michael Angelo, Raphael, Titian, and Lionardo da Vinci, show a complete insight into the characteristic merits of their works, and would make us wonder (if the case were at all singular) how he could enter with such force, delicacy, and feeling, into excellencies of which he never transplanted an atom into his own works. He saw, felt, and *wrote;* his impressions were profound and refined; but the expression of them must be instantaneous, such as gave the results of them with a stroke of the pen, as they were received by a glance of the eye, and he could not wait for the slow process of the pencil for embodying his conceptions in the necessary details of his own art.

We suspect Mr Barry did not succeed very well in copying the pictures he so well describes; because he appears to have copied but few—only one of Raphael, as far as we can find, and three from Titian, whom he justly considered as the model of colouring, and as more perfect in that department of the art than either Raphael or Michael Angelo were in theirs, expression and form, the highest excellence in which he conceives to have been possessed only by the ancients. In copying from the antique, however, he manifested the same aversion to labour, or to that kind of labour which, by showing us our defects, compels us to make exertions to remedy them. He made all his drawings from the antique by means of a *delineator*, that is, a mechanical instrument, to save the trouble of acquiring a knowledge both of form and proportion.

The consequences are before us in his pictures; namely, that all those of his figures which he took from these memorandums are deficient in everything but form, and that all the others are equally deficient in form and everything else. Mr Barry painted two pictures while abroad, his Adam and Eve, and his Philoctetes. The first of these he sent home as a specimen of his progress in the art. It does not appear to have given much satisfaction. His Philoctetes he brought home with him. It is a most wretched, coarse, unclassical performance, the direct opposite of all that he thought it to be. During his stay at Rome, he made an excursion to Naples, and was highly delighted with the collections of art there. All the time he was abroad, Mr Burke and his brothers not only were punctual in their remittances to him, but kept up a most friendly and cordial correspondence. For some time previous to his return to England, Mr Hamilton (afterwards Sir William) appears to have been almost the only person with whom he kept up any intimacy. It was on his return home through Milan that he witnessed, and has recorded with due reprobation, the destruction of Lionardo's Last Supper, which two bungling artists were employed to paint over by order of one Count de Firmian, the secretary of state.

In the spring of 1771 Mr Barry arrived in England, after an absence of five years. He soon after produced his picture of Venus, which, absurdly enough, has been compared to the Galatea of Raphael, the Venus of Titian, and the Venus de' Medici. Mr Barry flattered himself that he had surpassed the famous statue of that name, by avoiding the appearance of *maternity* in it. There is an engraving of it by Mr Valentine Green. In 1773 he exhibited his Jupiter and Juno on Mount Ida, which was much praised by some critics of that day. His Death of General Wolfe was considered as a falling off from his great style of art, which consisted in painting Greek subjects, and accordingly it is said to "have obtained no praise." His fondness for Greek costume was assigned by his admirers as the cause of his reluctance to paint portraits; as if the coat were of more importance than the face. His fastidiousness in this respect, and his frequent excuses or blunt refusals to go on with a portrait of Mr Burke which he had begun, caused a misunderstanding with that gentleman, which does not appear to have been ever entirely made up. The difference between them is said to have been widened by Burke's growing intimacy with Sir Joshua, and by Barry's feeling some little jealousy of the fame and fortune of his rival *in an humbler walk of the art.* About the same time he painted a pair of classical subjects, Mercury inventing the Lyre, and Narcissus looking at himself in the water, the last suggested to him by Mr Burke. He also painted an historical picture of Chiron and Achilles, and another of the story of Stratonice, for which last the Duke of Richmond gave him a hundred guineas. In 1773 there was a plan in contemplation for our artists to decorate the inside of St Paul's with historical and sacred subjects; but this plan fell to the ground, from its not meeting with the concurrence of the bishop of London and the archbishop of Canterbury, to the no small mortification of Barry, who had fixed upon the subject he was to paint,—the rejection of Christ by the Jews when Pilate proposes his release. In 1773 he published *An Inquiry into the real and imaginary Obstructions to the Acquisition of the Arts in England*, vindicating the capacity of the English for the fine arts, and tracing their slow progress hitherto to the Reformation, to political and civil dissensions, and, lastly, to the general turn of the public mind to mechanics, manufactures, and commerce. In the year 1774, shortly after the failure of the scheme of decorating St Paul's, a proposal was made, through Mr Valentine Green, to the same artists, Reynolds, West, Cipriani, Barry, &c., for ornamenting the great room of the Society for the Encouragement of Arts, Manufactures, and Commerce, in the Adelphi, with historical and allegorical paintings. This proposal was at the time rejected by the artists themselves; but, in 1777, Mr Barry made an offer to paint the whole himself, on condition of being allowed the choice of his subjects, and being paid by the society the expense of canvass, paints, and models. This offer was accepted, and he finished the series of pictures at the end of seven years, instead of two, which he had proposed to himself, but with entire satisfaction to the members of the society for whom it was intended, and who conducted themselves to him with liberality throughout. They granted him two exhibitions, and at different periods voted him 50 guineas, their gold medal, and again 200 guineas, and a seat among them. Dr Johnson remarked, when he saw the pictures, that, "whatever the hand had done, the head had done its part." There was published an excellent anonymous criticism on them, supposed to be by Burke, in answer to some remarks put forth by Barry in his descriptive catalogue on the *ideal* style of art, and the necessity of size to grandeur. His notions on both these subjects are very ably controverted, and, indeed, they are the rock on which Barry's genius split. It would be curious if Burke were the author of these strictures; for it is not improbable that Barry was led into the last error, here deprecated, by that author's *Essay on the Sublime and Beautiful.* The series consists of six pictures, showing the progress of human culture. The first represents Orpheus taming the savages by his lyre. The figure of Orpheus himself is more like that of a drunken bacchanal than an inspired poet or lawgiver. The only part of this picture which is valuable is the background, in one part of which a lion is seen ready to dart upon a family group milking near a cave, and, in another, a tiger is pursuing a horse. There is certainly a scope of thought and picturesque invention in thus showing indirectly the protection which civilization extends, as it were, over both man and animals. The second picture is a Grecian harvest, which has nothing Grecian in it. But we cannot apply this censure to the third picture of the Olympic Games, some of the figures in which, and the principal group, are exceedingly graceful, classical, and finely

Barry. conceived. This picture is the only proof Barry has left upon canvass that he was not utterly insensible to the beauties of the art. The figure of the young man on horseback really reminds the spectator of some of the Elgin marbles; and the outlines of the two youthful victors at the games, supporting their father on their shoulders, are excellent. The colouring is, however, as bald and wretched in this picture as in the rest, and there is a great want of expression. The fourth picture is the Triumph of Commerce, with Dr Burney swimming in the Thames, with his hair powdered, among naked sea-nymphs: the fifth, the Society of Arts distributing their annual prizes: and the sixth represents Elysium. This last picture is a collection of caricatured portraits of celebrated individuals of all ages and nations, strangely jumbled together, with a huge allegorical figure of Retribution driving Heresy, Vice, and Atheism into the infernal regions. The moral design of all these pictures is much better explained in the catalogue than on the canvass; and the artist has added none of the graces of the pencil to it in any of them, with the exception above made. Barry appears, however, to have rested his pretensions to fame as an artist on this work, for he did little afterwards but paltry engravings from his own paintings, and the enormous and totally worthless picture of Pandora in the assembly of the gods. His self-denial, frugality, and fortitude, in the prosecution of his work at the Adelphi, cannot be too much applauded. He has been heard to say, that at the time of his undertaking it, he had only 16s. in his pocket; and that he had often been obliged, after painting all day, to sit up at night to sketch or engrave some design for the printsellers, which was to supply him with his next day's subsistence. In this manner he did his prints of Job, dedicated to Mr Burke, of the Birth of Venus, Polemon, Head of Chatham, King Lear from the picture painted for the Shakspeare gallery, &c. His prints are caricatures even of his pictures; they seem engraved on rotten wood.

Soon after his return from the Continent, Barry was chosen a member of the Royal Academy; and in 1782 he was appointed professor of painting, in the room of Mr Penny, with a salary of L.30 a-year. The lectures which he delivered from the chair were full of strong sense and wholesome advice, both to the students and academicians. Among other things, he insisted much on the necessity of purchasing a collection of pictures by the best masters as models for the students, and proposed several of those in the Orleans collection. This recommendation was not relished by the academicians, who perhaps thought their own pictures the best models for their several pupils. Bickerings, jealousies, and quarrels arose, and at length reached such a height, that, in 1799, Barry was expelled from the Academy, soon after the appearance of his *Letter to the Dilettanti Society*; a very amusing but eccentric publication, full of the highest enthusiasm for his art, and the lowest contempt for the living professors of it. In 1800 he undertook a design or drawing to celebrate the union of the two kingdoms of Great Britain and Ireland. The profits of the two exhibitions of the Adelphi pictures are said to have amounted to above L.500. Lord Romney presented him with 100 guineas for his portrait, which had been copied into one of the pictures, and he had 20 guineas for a head of Mr Hooper. He probably received other sums for portraits introduced into the work. By extreme frugality, he contrived not only to live, but to save money. His house was twice robbed of sums which he kept by him; one of the times (in 1794) of upwards of L.100, a loss which was made up by the munificence of Lord Radnor, and by that of his friends the Hollises. After the loss of his salary, a subscription was set on foot by the Earl of Buchan to relieve him from his difficulties, and to settle him in a larger house to finish his picture of Pandora. The subscription amounted to L.1000, with which an annuity was bought, but of this he was prevented from enjoying the benefit, for on the 6th of February 1806 he was seized with a pleuritic fever, and died on the 22d of the same month. On the 14th of March the body was attended by a numerous and respectable train of his friends to the cathedral of St Paul's, where it was deposited. Barry || Barthélemy.

Mr Barry, as an artist, a writer, and a man, was distinguished by great inequality of powers and extreme contradictions in character. He was gross and refined at the same time; violent and urbane; sociable and sullen; inflammable and inert; ardent and phlegmatic; relapsing from enthusiasm into indolence; irritable, headstrong, impatient of restraint; captious in his intercourse with his friends; wavering and desultory in his profession. In his personal habits he was careless of appearances or decency; penurious, slovenly, and squalid. He regarded nothing but his immediate impulses, confirmed into incorrigible habits. His pencil was under no control. His eye and his hand seemed to receive a first rude impulse, to which it gave itself up, and paid no regard to anything else. The strength of the original impetus only drove him farther from his object. His genius constantly flew off in tangents, and came in contact with nature only at salient points. His writings are a greater acquisition to the art than his paintings. The powers of conversation were what he most excelled in; and the influence which he exercised in this way over all companies where he came, in spite of the coarseness of his dress, and the frequent rudeness of his manner, was great. Take him for all in all, he was a man of whose memory it is impossible to think without admiration as well as regret. (W. H–Z–T.)

BARRY, in *Heraldry*, is when an escutcheon is divided bar-ways, that is, across from side to side, into an even number of partitions, consisting of two or more tinctures, interchangeably disposed. In the blazon the word *barry* must be expressed, and the number of pieces specified; but if the divisions be odd, the field must be first named, and the number of bars expressed.

Barry-Bendy is when an escutcheon is divided evenly, bar and bend-ways, by transverse and diagonal lines, interchangeably varying the tinctures of which it consists.

BARS, a county of Hungary, in the circle of the Hither Danube, with a population of 138,000, and an area computed at 1044 square miles. See HUNGARY.

BARSAC, a town of France, on the Garonne, in the department of the Gironde, famous for its white wines, which are of the same class as those of Sauternes, but stronger. Pop. 2896.

BARTAS, GUILLAUME DE SALLUSTE DU, a French poet, born in 1544. He was employed by Henry IV. of France, in England, Denmark, and Scotland; and he commanded a troop of horse in Gascony, under the Marshal de Martingan. His principal work, *The Week, or the Creation of the World*, which has long since fallen into oblivion, once enjoyed a high reputation, thirty editions of it having been printed within six years after its appearance. It was translated into English by Joshua Sylvester. Du Bartas died in 1590, of wounds received in the battle of Ivry.

BARTER, or TRUCK, is the exchanging of one commodity for another. The word comes from the Spanish *baratar*, to deceive or circumvent in bargaining. See TRUCK.

BARTFELD, a town of Hungary, county of Saros, on the river Tepla. It has some trade in wine, corn, linen and woollen goods, paper, &c., and is noted for the mineral springs and baths in the vicinity. Pop. 6000.

BARTH, or BART, JEAN, a fisherman of Dunkirk, who rose to the rank of admiral, and is celebrated in the annals of France for his valour and naval exploits. He died in 1702, aged fifty-one. (*Histoire de Jean Bart*, by Vanderest; Paris, 1841, 8vo.)

BARTHÉLEMY, JEAN-JACQUES, a celebrated French writer, born at Cassis, a little seaport on the shores of the Mediterranean, on the 20th January 1716. At twelve

Barthélemy.

years of age he entered the college of the Oratory at Marseilles, under the care of Father Rénaud, a person of taste and ability, who soon discovered similar qualities in his pupil, and became uncommonly attentive to his progress. M. de Visclède, a man of letters, and friend to the former, also concurred with him in his endeavours; and young Barthélemy's career soon became equally rapid and brilliant.

He had resolved to dedicate himself to the church; but, in order to qualify himself, it became necessary to change his place of residence, as M. de Belzunce, bishop of Marseilles, refused to admit to holy orders the students of the Oratory. Barthélemy, therefore, quitting his old masters with regret, found himself under the necessity of studying philosophy and theology under the Jesuits.

Following a plan of education independently of the professors, he was indefatigable in his study of the Greek, Hebrew, Chaldee, and Syriac languages. His passion for learning, however, nearly cost him his life; for he fell dangerously ill, and did not recover his strength until he had entered the seminary where he received the tonsure.

In this retreat he dedicated his leisure hours to the study of Arabic; and, with the assistance of a young Maronite who had been educated at Rome, he soon acquired a perfect knowledge of that language. By way of return, his new friend proposed to him to render all the services in his power to the Maronites, Armenians, and other Catholic Arabians, who were but slightly acquainted with the language of the country in which they resided; in other words, he expressed a wish that Barthélemy would announce the word of God to them in their native tongue, and with that view presented him with some Arabic sermons composed by a Jesuit who had belonged to the Propaganda. Accordingly Barthélemy got one or two of them by heart, and pronounced them in a spacious hall belonging to the seminary, to the entire satisfaction of his oriental auditors.

When Barthélemy had finished his education at the seminary, he retired to Aubagne, and spent some time in the bosom of his family. He made frequent visits, however, to Marseilles; and among the learned of that city to whom he attached himself in a particular manner was M. de Cary, the possessor of a fine cabinet of medals and a valuable library. They spent whole days together in conversing on literary subjects; after which Barthélemy, as if insatiable in his thirst for knowledge, would retire to the Minims, where Father Sigaloux, a correspondent of the Academy of Sciences, was employed in making astronomical observations; and in these labours the young abbé became his associate.

In 1744 he repaired to Paris, with the view of devoting himself entirely to literature, and carried with him a letter to M. de Boze, keeper of the medals, and perpetual secretary of the Academy of Inscriptions and Belles-Lettres.

The increasing age and declining health of De Boze rendered it necessary that he should have assistance; and Barthélemy was selected as his colleague. From that moment the abbé dedicated both his days and nights to the study of those medals which De Boze had been prevented by his infirmities from arranging.

On the death of M. de Boze in 1753, Barthélemy, who had been his colleague during eight years, was nominated his successor.

M. de Stainville, afterwards better known during his administration by the title of Duke de Choiseul, being appointed ambassador to Rome in 1754, Madame de Stainville, a lady of great personal beauty, and an enthusiastic admirer of learning and literary men, conceived a particular regard for the abbé; and it was proposed that he should occupy a place in their carriage on this occasion, and make the tour of Italy along with them. Such a proposition could not fail to be highly flattering; and having been accepted, he set out soon after, and in November arrived at Rome. Pope Benedict XIV., who then wore the tiara, and was a learned man himself, distinguished Barthélemy by the most courteous reception. But his stay at Rome was not of long duration; for he was desirous of visiting Naples, rendered at that period particularly interesting to an antiquary, by the recent discoveries made in its neighbourhood. During a whole month he and his fellow-travellers were occupied in admiring the curiosities of that capital, and in studying ancient literature; after which they took a journey of thirty leagues to examine the monuments of Grecian architecture still extant amidst the splendid ruins of the ancient city of Pæstum.

Barthélemy.

As he was exceedingly desirous of presenting the learned men of France with a specimen of the ancient writing employed in the Greek manuscripts, he addressed himself on this subject to his friend Mazocchi, and also to M. Paderno, who superintended the collection of antiquities from Herculaneum and Pompeii in the palace of Portici; but both replied that they were expressly enjoined not to make any communication on the subject. On this he solicited permission to look, for a few minutes only, on a page of a manuscript which had been cut from top to bottom since its discovery. It contained twenty-eight lines, and Barthélemy read it over six different times with extreme attention, after which he transcribed the precious fragment on a piece of paper, from memory. On making a mental collation between the copy and the original, he corrected two or three trifling errors that had escaped his attention. Having thus rendered himself master of a fac-simile of the manuscript, which related to the persecution of the Greek philosophers during the time of Pericles, he transmitted the literary plunder in the course of that very day to the Academy of Belles-Lettres; strictly enjoining secrecy, however, that Mazocchi and Paderno might escape all manner of blame.

M. de Stainville having been appointed ambassador to the court of Vienna in 1757, the abbé accompanied his lady thither. On his arrival he found that his friend and protector had made certain engagements with the French ministry with the view of gratifying his passion for antiquities; and, in consequence, he received permission to visit, at the king's expense, Greece and the seaports of the Mediterranean, where he was to collect new treasures, and return with them to his native country by Marseilles. But notwithstanding all the attractions which this project presented, his scrupulous attachment to his duty prevailed over his passion for knowledge; and as he deemed it highly improper that the cabinet of medals should remain so long shut, he abandoned the scheme of visiting the Levant.

Towards the end of 1758, M. de Stainville, now become Duke de Choiseul, was nominated minister for foreign affairs, which enabled him to provide for his friend; and having requested him to state the sum which would make him easy for life, Barthélemy instantly mentioned 6000 livres a year, blushing at the same time at the largeness of the demand.

In 1759 the duke presented him with a pension on the archbishopric of Alby; in 1765 he conferred on him the treasurership of St Martin de Tours; and, in 1768, he made him secretary-general to the Swiss guards. In addition to these the abbé also enjoyed a pension of 5000 livres on the *Mercure de France*. By these means his income was now large; but he employed it nobly; for he distributed the surplus, which was considerable, among indigent men of letters.

In 1771 M. de Choiseul was superseded by the Duke d'Aiguillon, and exiled to his estate at Chanteloupe. On this occasion he was as usual forsaken by the courtiers who had basked in the sunshine of his favour. But he was not deserted by the grateful antiquary, who instantly repaired to Chanteloupe to pay his respects to the fallen minister.

Barthélemy was now in possession of more than L.1200 sterling per annum, of which he distributed between L.300 and L.400 in assisting men of letters. He also educated and established in life three nephews, one of whom was successively an ambassador and a director; at the same time

Barthélemy.

supporting the rest of his family in Provence, and collecting a noble library, which he disposed of some years before his death. But after having thus possessed an ample income during more than twenty years, Barthélemy at last, in consequence of the suppression of places and appointments occasioned by the Revolution, found himself reduced to live on a pittance barely adequate to furnish the necessaries of life. He was never heard to complain, however, nor, indeed, did he seem to perceive the change; and while age and infirmities permitted him to walk from one end of Paris to the other, in order to visit his kind friend Madame de Choiseul, his happiness suffered no apparent diminution.

In 1788 appeared his celebrated work, entitled *Voyage du ieune Anacharsis en Grèce, dans le milieu du quatrième siècle avant l'ère Chrétienne.* He had begun it in 1757, and, during an uninterrupted succession of thirty years, occupied his leisure hours in bringing it to maturity. His hero, a young Scythian, descended from the famous philosopher Anacharsis, whose name he bears, is supposed to repair to Greece for instruction in his early youth, and after making the tour of her republics, colonies, and islands, to return to his native country and write this book in his old age, after the Macedonian hero had overturned the Persian empire. In the manner of modern travellers, he gives an account of the customs, government, and antiquities of the country he is supposed to have visited; a copious introduction supplies whatever may be wanting in respect to historical details; whilst various dissertations on the music of the Greeks, on the literature of the Athenians, and on the economy, pursuits, ruling passions, manners, and customs, of the surrounding states, supply ample information on the subjects of which they treat. The author, indeed, is not profound; and the young Scythian seldom penetrates much below the surface. But his remarks are commonly judicious, and to respectable erudition he unites singular skill in the distribution of his materials, and a happy talent for presenting his subject in the most agreeable and attractive form. The assumed character is so admirably sustained throughout, that we can scarcely persuade ourselves we are not perusing a book of real travels, and communing with an actual personage who has recorded his observations and experience for the instruction and improvement of his countrymen.

In 1789 Barthélemy became a candidate for a chair in the French Academy; and was enrolled among its members by acclamation. The speech delivered by the abbé on his inauguration is equally remarkable for its simplicity and modesty.

In 1790 M. de St Priest, minister of the department of Paris, made him an offer of the situation of librarian to the king, then vacant by the resignation of M. le Noir; but this very flattering proposal was not accepted.

But while Barthélemy was thus refusing one of the most honourable offices which a man of letters could at that time aspire to, he did not neglect the department which had so long been confided to his charge. His ardour respecting everything that concerned the cabinet of medals remained unabated through life; and he now found means to have his nephew, Barthélemy Courcy, associated with him in his labours. This grand collection had received a considerable increase, and had been embellished with a number of fine specimens since it was first confided to his care. To enrich it still more, he carried on an extensive correspondence not only with the various provinces of France, but also with every part of Europe.

In the mean time the health of the learned medalist declined daily, and in 1792 his strength had so much failed him that, towards the close of the year, he became subject to fainting fits which deprived him of the exercise of his faculties for several hours together. Being naturally calm and courageous, he did not appear to be the least affected by these accidents; his friends, however, considered them as sypmtoms of approaching dissolution. He was now seventy-eight years of age, sixty of which had been spent in literary toils; and it might therefore have been expected that, even at that agitated period, the venerable veteran would have been suffered to die in peace. But it was not so. On the 30th of August 1793 this feeble old man was denounced as an aristocrat, and his nephew and several other young men employed about the library were included in the charge. The accusation proceeded from a person of the name of Duby, a clerk in the library, and it was conveyed in a letter written by him to a person of the name of Chrétien, a pastry-cook (who happened to be a member of the section before which it was first read), and then transmitted to the municipality. It was of no consequence that Duby did not know Chrétien, nor Chrétien Duby, and that Barthélemy was not acquainted with either. A warrant was immediately issued against the supposed culprits, and the fact was signified by the officers of justice, to the abbé, while at Madame de Choiseul's on the morning of the 2d of September. On receiving the intimation he instantly rose, without discovering any symptoms of perturbation, and taking his leave of that lady, was conducted to the Magdelonettes, where he found his nephew Courcy. Such, however, was the respect paid to his virtue and his talents, even within the walls of a prison, that he was received with every expression of regard by the inhabitants of that dreary mansion: even the jailer paid him the most respectful attention. He was lodged in a little apartment along with his relation; and in the course of that evening he received a visit from Madame de Choiseul, who had taken care to notify the event to the government. No sooner was the Committee of Public Safety informed that the Abbé Barthélemy had been included in the order, which was meant to extend only to some of the subalterns in the library, than orders were instantly issued for his release; and such zeal did the clerks in the public offices display in forwarding the necessary papers for his liberation, that he was awakened from his sleep at eleven o'clock at night, and conducted to the house of his fair friend. In a few weeks afterwards, the office of national librarian having become vacant by the death of Carra and the resignation of Chamfort, who had held it jointly, it was offered to the abbé, with the most flattering marks of respect. But his advanced age and increasing infirmities did not admit of his accepting the offer.

Barthélemy || Barthez.

He expired without a struggle on the 30th April 1795, retaining to the last moment full possession of his faculties. In his person Barthélemy was above the middle size; and, if we are to credit his admirers, his countenance displayed an air of antiquity wonderfully corresponding with his studies. His bust, sculptured by Houdon, is allowed to be a masterpiece of art; and that able artist has contrived to infuse into the physiognomy a mixture of the mildness, simplicity, goodnature, and elevation of soul, so visible in the original.

BARTHELEMY DE GROAIN, *St*, a village of France, in the department of Isere, and arrondissement of Grenoble. In the vicinity is a burning fountain, *i.e.*, inflamed carburetted hydrogen.

BARTHEZ, or BARTHÈS, PAUL JOSEPH, one of the most celebrated physicians of the university of Montpellier, equally remarkable for the variety and extent of his erudition, and for the vigour of mind displayed in his abstruse speculations. He was born on the 11th of December 1734, at Montpellier, and received his early education at Narbonne, where his family resided, and afterwards at Toulouse. He soon gave decisive indications of those talents with which nature had endowed him, and which destined him to occupy a distinguished station among the learned men of the age. He commenced the study of medicine at Montpellier in 1750, and in 1753, when he had only attained his nineteenth year, he received his doctor's degree. He afterwards occasionally visited Paris, where he attracted the notice, and acquired the friendship, of the most distinguished literati of

Barthez. that period. In 1756 he obtained the appointment of physician to the military hospital in Normandy, attached to the army of observation commanded by Marshal d'Estrées. The zeal and assiduity with which he discharged the duties of his new office were most exemplary. He spent his whole time at the hospital, and often passed the night at the bedside of his patients. Though naturally of a good constitution, his strength was not commensurate with the ardour of his mind. His health suffered much from the intensity of his application, and he was often very near falling a sacrifice to fevers and other disorders which he caught from the patients in the hospital; and he thence became liable ever after to attacks of dysentery and bilious fever.

Many of the observations and inquiries which he made during this period were published in the *Memoirs of the Academy of Sciences;* and two of his first productions were crowned by the Academy of Inscriptions. In 1757 his services were required in the medical staff of the army of Westphalia, where he had the rank of consulting physician. On his return to Paris he contributed several articles to the *Journal des Savans* and to the *Encyclopédie;* and was, indeed, for a time considered one of the editors of the former of those works. In 1761 he obtained a medical professorship at Montpellier, in which his abilities as a teacher soon shone forth with unrivalled lustre. His success was the more honourable inasmuch as his colleagues, Lamure, Leroy, and Venel, were men of distinguished reputation, and had raised the school to a high pitch of celebrity.

In 1774 he was created joint chancellor of the university, with the certainty of succeeding singly to the office on the death of his colleague, which happened in 1786. He afterwards took the degree of doctor in civil law, and was appointed counsellor to the supreme court of Aids at Montpellier. In 1780, he was induced to fix his residence in Paris, having been nominated consulting physician to the king, with a brevet of counsellor of state, and a pension of a hundred louis. Honours now crowded upon him; he was admitted free associate to the Academies of Sciences and of Inscriptions, and appointed first physician to the Duke of Orleans, in the room of Tronchin. His reputation increased in proportion as his merits were displayed on a wider theatre. He practised as a physician at Paris for nearly ten years, and received the most flattering testimonials of public approbation.

This brilliant career was suddenly interrupted by the great political revolution which broke out at this period, and by which the interests of every individual in France, however tranquil his pursuits or obscure his station, were more or less immediately affected.

Barthez was now obliged to quit Paris, and seek in his native province that tranquillity and repose which the stormy aspect of the times forbade him to hope for in a more conspicuous station, holding, as he did, opinions so much at variance with the new order of things. Though he had lost the greater part of his fortune, acquired by so much labour, and was deprived of the honours to which he possessed so just a claim, he determined, upon his retiring to Carcassone, to practise his profession gratuitously, and devote all his leisure hours to the speculative studies connected with it, which had been the ruling passion of his life. It was in this retreat that he gave to the world his *Nouvelle Mécanique des Mouvemens de l'Homme et des Animaux*, which appeared in 1798.

On the re-establishment of the College of Medicine at Montpellier, Barthez was naturally looked up to as the person best calculated to revive its former fame. But age and infirmity operated to dissuade him from resuming the laborious office of teacher; and he was accordingly nominated honorary professor. In 1802 he received several marks of favour from the new government under Buonaparte; he was nominated titular physician to the government, and afterwards consulting physician to the emperor, and member of the Legion of Honour. Barthius.

His *Traité des Maladies Goutteuses*, in two volumes octavo, appeared in 1802; and he afterwards occupied himself in preparing for the press a new edition of his *Elémens de la Science de l'Homme*, of which he just lived to see the publication. His health had been declining for some years before his death, which took place soon after his removal to Paris, on the 15th of October 1806, in the seventy-second year of his age. He bequeathed his books and manuscripts to M. Lordat, who, in consequence, published two volumes of *Consultations de Médecine*, Paris, 1810, 8vo, to which he prefixed a preface of his own. Another posthumous work of Barthez, the *Traité du Beau*, preceded by some account of his life, was edited in 1807 by his brother, M. Barthez de Marmorières, who is known as the author of agricultural essays, and projects for improving the maritime coast of Languedoc, together with some translations from the oriental languages; and who has sometimes been mistaken for the subject of the present article.

Barthez has enjoyed a much higher reputation on the Continent than in this country, where, indeed, his writings are comparatively little known. The work which has chiefly contributed to establish his fame, and which contains the development of his peculiar opinions on physiology, is the *Nouveaux Elémens de la Science de l'Homme*. It is not written, however, with the simplicity and clearness which might have been expected from one who had been in the constant habit of instructing others, and whose lectures were generally admired as possessing those qualities in an eminent degree.

Amidst many vague and unprofitable speculations, his work contains a great store of facts, which are often instructive, though sometimes they expose the credulity of the author.

In the preface to his *Nova Doctrina de Functionibus Naturæ Humanæ*, he has given an excellent arrangement of the general principles of the objects to be kept in view in the medical treatment of diseases. He treats of this subject more at large in his treatise *De Methodo Medendi*, published at Montpellier in 1777, and also in the preface to his *Traité des Maladies Goutteuses*.

The writings of Barthez appear to have had considerable influence in overthrowing many of the crude and preposterous theories which had prevailed in the schools of medicine; and, however he may have been seduced from the path of genuine philosophy by an excessive disposition to generalize, and an overweening fondness for abstruse speculation, he still deserves the praise of being an original thinker, and of standing pre-eminent among his contemporaries for the courage with which he shook off the trammels of authority, in a university where it had ruled with despotic sway, and where the dogmas of antiquity were held in peculiar reverence. (P. M. R.)

BARTHIUS, Gaspard, a learned German philologist, born at Custrin, in Brandenburg, on the 22d June 1587. M. Baillet has inserted his name among his *Enfans Célèbres*, upon the ground that at twelve years of age he had translated the Psalms of David into Latin verse of every measure. Upon the death of his father, who was professor of the civil law at Frankfort, counsellor to the elector of Brandenburg, and chancellor at Custrin, he was sent to Gotha, then to Eisenach, and afterwards, according to custom, went through all the different universities in Germany. He afterwards travelled into Italy, France, Spain, and England. He resided latterly at Leipzig, where he died in 1658. He wrote a great number of books, the principal of which are, 1. His Adversaria, a large volume in folio, the second and third volumes being left by him in manuscript; 2. A Translation of Æneas Gazæus; 3. A large volume of Notes upon Claudian, in 4to; 4. Three large volumes upon Statius.

Bartholinus. || Bartholomew.

BARTHOLINUS, GASPARD, a learned writer, born in 1585, at Malmoë in Scandinavia. At three years of age he had such a quick capacity, that in fourteen days he learned to read; and in his thirteenth year he composed Greek and Latin orations, and delivered them in public. When he was about eighteen he went to the university of Copenhagen, and afterwards studied at Rostock and Wittemberg. He then travelled through Germany, the Low Countries, England, France, and Italy, and was received with marked respect at the different universities he visited. In 1613 he was chosen professor of physic in the university of Copenhagen, and filled that office for eleven years, when, falling into a dangerous illness, he made a vow, that if it should please God to restore him, he would apply himself solely to the study of divinity. He recovered, observed his vow, and soon after obtained the professorship of divinity, with the canonry of Rotschild. He died on the 13th of July 1630, after having written nearly fifty works on different subjects.

BARTHOLINUS, *Thomas*, a very celebrated physician, son of the former, was born at Copenhagen in 1619. After studying some time in his native country, he went in 1637 to Leyden, where he studied medicine for three years. He then travelled into France, and resided two years at Paris and Montpellier, in order to improve himself under the distinguished physicians of those universities; after which he visited Italy, remained three years at Padua, and then went to Basle, where he obtained the degree of doctor in philosophy. Returning to Copenhagen, he was appointed professor of mathematics in 1647, and next year was nominated to the chair of anatomy, which was better suited to his genius and inclination. This he held for thirteen years, distinguishing himself by several observations respecting the lacteal and lymphatic vessels, shortly after their discovery by Olaus Rudbeck. His close application, however, having rendered his constitution very infirm, he resigned his chair in 1661; but the king of Denmark allowed him the title of "honorary professor." He now retired to a little estate he had at Hagestaed, near Copenhagen, where he hoped to spend the remainder of his days in peace and tranquillity; but his house having been burnt in 1670, his library, with all his books and manuscripts, was consumed. In consideration of this loss, the king appointed Bartholinus his physician, with a handsome salary, and exempted his land from all taxes; the university of Copenhagen also chose him for their librarian; and, in 1675, he was honoured with a seat in the grand council of Denmark. He died on the 4th of December 1680. He wrote, Anatomia Gaspardi Bartholini Parentis, novis Observationibus primum locupletata, 8vo; De Monstris in Natura et Medicina, 4to; De Armillis Veterum, præsertim Danorum, Schedion, 8vo; and several other works.

BARTHOLOMEW, ST, one of the twelve apostles, generally supposed to have been the same individual who in St John's Gospel is called Nathanael. This appears to have been his real name, while Bartholomew merely expresses his filial relation. He was a native of Cana in Galilee (John xxi. 2). He was introduced by Philip to Jesus, who, on seeing him approach, at once pronounced that eulogy on his character which has made his name almost synonymous with sincerity: he was a witness of the resurrection and the ascension, and returned with the other apostles to Jerusalem. Of his subsequent history we have little more than vague traditions. According to Eusebius (*Hist. Eccles.* v. 10), when Pantænus went on a mission to the Indians (towards the close of the second century), he found among them the Gospel of Matthew, written in Hebrew, which had been left there by the apostle Bartholomew. Jerome (*De Vir. Illustr.* c. 36) gives a similar account. But the name Indians is applied by ancient writers to so many different nations, that it is difficult to determine the scene of Bartholomew's labours. Mosheim (with whom Neander agrees) is of opinion that it was a part of Arabia Felix, inhabited by Jews, to whom alone a Hebrew gospel could be of any service. According to the received tradition, this apostle was flayed alive and crucified with his head downwards, at Albanopolis in Armenia, or, according to Nicephorus, at Urbanopolis in Cilicia. A spurious gospel which bears his name is in the catalogue of apocryphal books condemned by Pope Gelasius. Bartholomew || Barton.

The festival of St Bartholomew is celebrated on the 24th of August. On the night of this festival, in the year 1572, took place that foul and treacherous massacre of the Huguenots in France, which has stamped with infamy the memory of the detestable Catherine de' Medici and her son Charles IX. This massacre lasted three days. See FRANCE.

BARTHOLOMEW, *St*, one of the West India Islands, 30 miles north of St Christopher's. Lat. 17. 55. 35. N. Long. 62. 50. W. Though destitute of fresh water except what is supplied by rain, it is very fertile, producing sugar, cotton, and tobacco. It is of an irregular oblong shape, and has an area of 35 square miles, with a population of 18,000. Being surrounded by rocks and shoals, it is difficult of access, but its harbour, Le Carenage, on the western side, is safe and commodious. This island was ceded by France to Sweden in 1784.

BARTIZAN, in *Architecture*, a small turret projecting from the angle of a square tower, or from the parapet.

BARTOLOCCI, JULIUS, a learned monk, and professor of Hebrew at Rome, was born at Celano in 1613. He distinguished himself by writing a Hebrew and Latin catalogue of the Hebrew writers and writings, entitled *Bibliotheca Magna Rabbinica*, &c., in four volumes folio. This important work was continued by his disciple Imbonati. Bartolocci died in 1687.

BARTOLOMEO, FRANCESCO, a celebrated painter, born at Savignano near Florence, in the year 1469, was the disciple of Cosimo Rosselli, but was much more indebted to the works of Lionardo da Vinci for his extraordinary skill in painting. He was so well versed in the principles of design, that Raphael, after quitting the school of Perugino, applied to this master, and studied under him the rules of perspective, with the art of managing and uniting his colours. He painted both portraits and historical pieces; but from conscientious scruples, he seldom drew naked figures. He died in 1517, aged forty-eight.

BARTOLOZZI, FRANCESCO, a very celebrated designer and engraver, was the son of a silversmith at Florence, in which city he was born about the year 1730. After studying at Venice and at Rome, in 1764 he came to England at the invitation of Mr Dalton, the king's librarian, and soon afterwards was elected a member of the Royal Academy. He was induced by an offer of the Prince Regent of Portugal to remove to Lisbon, where it is supposed he died about the year 1815; though some place that event at London in 1819. The productions of his graver are very numerous, and are greatly esteemed by collectors.

BARTON, BENJAMIN SMITH, M.D., an eminent American naturalist, who was the first professor of botany and natural history in a college in the United States. He was born in Pennsylvania in 1766. He studied for two years at Edinburgh, and afterwards graduated at Göttingen. He began to practise his profession at Philadelphia, and soon obtained a respectable share of employment. In 1790 he was appointed to the professorship above mentioned in Philadelphia College; in 1802 was chosen president of the American Philosophical Society; was made professor of materia medica; and on the death of Dr Rush he obtained the chair of practical medicine. By his lectures and his writings he may be considered as the founder of the American school of natural history, which has risen to such a high rank in that branch of science. He died in 1815.

Barton-on-Humber || Basedow.

BARTON-ON-HUMBER, a market-town in the hundred of Yarborough and county of Lincoln. It stands on the Humber, six miles S.W. of Hull, with which town it has steam communication. Its principal trade is in corn and flour, and it has manufactures of ropes, sacking, bricks, and tiles. It has two parish churches. Market-day, Monday. Pop. in 1851, 3866.

BARTSCH, ADAM VON, the author of the most valuable dictionary of engravers, entitled *Le Peintre Graveur*, in 21 vols. 8vo, 1803–21. He was born at Vienna in 1757, and died there in 1821. From 1781 he was keeper of the imperial cabinet of prints.

BARUCH, THE PROPHECY OF, one of the apocryphal books subjoined to the canon of the Old Testament. Baruch the son of Neriah was the disciple and amanuensis of the prophet Jeremiah; and his prophecy has by some been reckoned part of that of Jeremiah. It is difficult to determine in what language this prophecy was originally written. Three copies of it are still extant, one in Greek, and the other two in Syriac; but which of these, or whether any one of them, is the original, remains uncertain.

BARYTES, or BARYTA, heavy earth. See MINERALOGY and CHEMISTRY.

BARYTONE (βαρυς and τονος), in *Music*, denotes a male voice intermediate between a bass and a tenor.

BARYTONIUM, in *Greek Grammar*, denotes a verb which has no accent marked on the last syllable, the grave accent being understood.

BAS, JACQUES PHILLIPE LE, a celebrated French engraver. He particularly excelled in landscapes and small figures. He was born at Paris in 1707, and died there in 1783.

BAS-RELIEF. See *BASSO-RILIEVO*.

BASALT. See MINERALOGY.

BASAN, or BASHAN, in *Ancient Geography*, a territory beyond Jordan, mentioned in Scripture, and called by Josephus, Eusebius, and Jerome, *Batanæa*. The sacred writers include in Bashan that part of the country eastward of the Jordan which was given to the half tribe of Manasseh, situated to the north of Gilead. After the Babylonish captivity it was subdivided into Batanæa or Basan, Trachonitis, Auranitis, and Gaulonitis. To settle the limits of these, however, is now impossible. Bashan was famous for its pastures and large breed of cattle.

BASCINET, BASINET, or BASNET, a light helmet generally without a vizor, and so called from its resemblance to a basin. (See Grose on *Ancient Armour*.)

BASEDOW, JOHANN BERNHARD, a celebrated German writer, born at Hamburg, the 11th September 1723, was the son of a hairdresser. Ill treatment made him abandon his father's house. A physician in a neighbouring village took him into his service, and shortly after persuaded him to return home to his father. Being placed in one of the lower classes of the college of St John, the severity of his masters rendered him harsh and violent himself. Forced to submit to a slow and rigorous method of study, he contracted a dislike to patience and regularity, which exercised a marked influence over the whole course of his life. Poor but intelligent, he often performed their tasks for schoolfellows who could afford to pay for it; and they, in return, invited him to their parties of pleasure, which contributed to those habits of irregularity by which his health and reputation often suffered. In 1744 Basedow went to Leipzig to study theology. He gave himself up entirely to the instructions of Crusius the professor, and to the study of philosophy. This at first made him sceptical in theology; a more profound examination of the sacred writings, and of all that relates to them, brought him back to the Christian faith; but, in his retirement, he formed his belief after his own ideas, and it was far from orthodox. Having returned to Hamburg, he lived there without any employment till 1749, when M. de Quaalen, privy-councillor of Holstein, appointed him preceptor to his son. Basedow now began to apply himself to the subject of education. At first he would not teach his pupil Latin otherwise than by talking with him in Latin; and he wrote a dissertation on this subject, published at Kiel in 1751, *Inusitata et optima honestioris Juventutis erudiendæ Methodus*. In 1753 he was chosen professor of moral philosophy and belles-lettres in the academy of Soroë in Denmark. Here, between the years 1758 and 1764, he published several works of a heterodox character, which exposed him to the opposition of the magistrates and the odium of the people. Constantly persecuted in his theological career, he would have fallen the victim of his incautious zeal, if the Count de Bernstoff, minister of state, and J. A. Cramer, another officer of the court of Copenhagen, had not taken him under their protection. He left off giving lessons without losing his salary; and, towards the end of 1767, he abandoned theology to devote himself with the same ardour to education, of which he conceived the project of a general reform in Germany. He began by publishing *An Address to the Friends of Humanity, and to Persons in Power, on Schools, on Education, and its Influence on Public Happiness, with the Plan of an Elementary Treatise on Human Knowledge*; Hamburg, 1768. He proposed the reform of schools and of the common methods of instruction, and the establishment of an institute for qualifying teachers; soliciting subscriptions for the printing of his elementary work, where his principles were to be explained at length, and accompanied with plates. For this object he required 5050 crowns. The subscriptions presently amounted to 15,000 crowns: the Empress of Russia, Catherine II., sent a thousand crowns, the King of Denmark nine hundred. In 1770 appeared at Altona the first volume of his *Method for Fathers and Mothers of Families, and for the Chiefs of the People*, which was followed by other treatises on education. In his travels he had been well received by the Prince of Anhalt-Dessau, who promised him his protection. From that time he had resolved to establish an institute for education at Dessau, and to apply his principles himself in forming disciples, who might spread them over all Germany. Little calculated by nature or habit to succeed in an employment which requires the greatest regularity, patience, and attention, he, however, engaged in this new project with all his accustomed ardour. The name of *Philanthropinon* appeared to him the most expressive of his views; and he published at Leipzig in 1774 a pamphlet entitled *The Philanthropinon founded at Dessau*, containing the details of his plan. He immediately set about carrying it into execution; but he had few scholars, and the success by no means answered his hopes. The institution, badly managed, became a theatre of quarrels between Basedow and the masters who taught in it under his direction. The assistance of the celebrated Campe, a journal which they both composed together, under the title of *School Dialogues*, from 1777 to 1779, and a public examination which went off with eclat, gave a transient splendour to the *Philanthropinon*; but in a short time Basedow quarrelled with Campe, made complaints against his prince, quitted, and again returned to the care of the institution, exemplifying in all his conduct the effects of coarse manners and bad temper. He was at length drawn into the most scandalous disputes with Professor Wolke, his former coadjutor. The institution was finally shut up in 1793. Basedow died at Magdeburg on the 25th July 1790. His work *On the Education of Princes destined to the Throne* has been translated into French by Bourjoing. A list of his writings may be seen in Meusel's *Lexicon of German Writers from* 1750 *to* 1800, and an account of his life in Schlichtegroll's *Necrology for* 1790. (W. H–Z–T.)

Basel.

BASEL, BASLE, or BALE, a canton in the N.W. of Switzerland, with an area of 139 geographical square miles. It is bounded on the N.W. by France, on the N. by the grand

Basel ‖ Bashaw.

duchy of Baden, E. by the canton of Aargau, and S. and S.W. by those of Solothurn and Berne. The country is generally mountainous, being traversed by the Jura chain; but it abounds in excellent pasturage, and numerous herds of cattle are reared there. The northern part of the canton is best suited for agriculture, being watered by the Rhine and numerous small mountain streams, besides the more considerable rivers of the Birse and the Ergolz, in whose valleys the vine and other fruits are cultivated. The mountains attain an elevation of from 3000 to 4000 feet; and the climate is mild and salubrious. The principal manufactures are ribbons, woollen, linen, and cotton goods, leather, paper, iron and steel wares. Basel was admitted into the Swiss confederation in 1501, and furnishes a contingent of 918 men. In consequence of a revolt of the country population against the aristocratic government of the city, this canton was divided in 1832 into two sub-cantons; viz., Basel-stadt, or Bale-ville, comprising the city and several of the neighbouring communes; and Basel-landschaft, or Bale-campagne, with the remaining communes of the canton. Pop. of Bale-ville in 1850, 29,555; of whom 24,083 were Protestants, and 5508 Roman Catholics; pop. of Bale-campagne, 47,830, of whom 38,818 were Protestants, and 9052 Roman Catholics; the former sending one, and the latter two members, to the national council. See SWITZERLAND.

BASEL, or BALE, the capital of the above province, is situated on both sides of the Rhine, 43 miles north of Berne, in Lat. 47. 33. 36. N. Long. 7. 35. 35. E. Great Basel, or that portion of the city which lies on the south side of the river, is connected with Little Basel on the opposite side by a handsome stone bridge 600 feet long. Its ancient fortifications are still in a good state of preservation, and the town is generally well built; but the streets are narrow, and it has few public edifices worthy of notice. The cathedral is a fine old Gothic edifice, founded about the beginning of the eleventh century, and contains the tombs of Erasmus, Œcolampadius, and other eminent persons.

Besides the university, which was founded by Pope Pius II. in 1459, Basel possesses an extensive public library, containing a valuable collection of MSS., a picture gallery, a museum, gymnasium, botanical garden, an orphan asylum and institution for deaf mutes, a theological institute, &c. It is the seat of an active transit trade between France, Germany, and Switzerland; and it has important manufactures of silk, linen, cotton, leather, paper, &c. Basel was the seat of a great council from 1431 to 1448; and here, in 1795, France concluded a treaty with Prussia and with Spain. It is connected by railway with Strasburg, from which it is 60 miles distant. Pop. 24,000. Basel was the birthplace of Euler, Holbein, and Bernouilli.

BASHAN. See BASAN.

BASHARIANS, a sect of Mahometans, being a branch or subdivision of the Motazalites. They maintain the tenets of Bashar Ibn Motamer, a leading teacher among the Motazalites, but who varied in some points from the general tenets of the sect, carrying man's free agency even to the extent of making him independent.

BASHAW, more commonly written Pashá or Pachá, a Turkish governor of a province or district. Nothing more s necessary to raise an Osmanli to the dignity of pasha than the firman of the grand seignior; but some ceremonies are usually observed at his investiture or installation. The badge of a pasha's authority, as well as the emblem of his rank, is the horse-tail, and he takes precedence according to the number of these in his banner. The highest rank usually conferred, however, is that of pasha of three tails. The pashas are the grand seignior's lieutenants, and exercise the supreme military and civil power in their respective provinces. But many of them own little more than a nominal subjection to the Porte, although they submit to pay it an annual tribute; and some are almost always in a state of open rebellion against its authority. Religion, in fact, is the only connecting principle which keeps the different parts of the Ottoman empire together; but, fanatical as the Moslemin almost universally are, the case of Egypt shows how frail a tie this may become, and how easily the bundle of rods may be dissolved. In fiscal matters, the pasha ordinarily acts as a horse-leech to his more immediate subjects, and serves as a sponge to the sultan, who frequently contrives to squeeze out a portion of the blood with which he is gorged, and, after a time, kindly presents him with a bowstring, and thus becomes ultimate heir to his private accumulations.

Bashee Isles ‖ Basil.

BASHEE ISLES, a cluster of small islands in the Chinese Sea, due north of Luzon, the largest of the Philippines. They are five in number, with four rocky islets. They were visited by Dampier the English navigator in 1687, and named by him Orange, Monmouth, Grafton, Goat, and Bashee Islands. These islands possess a fertile soil, and produce abundance of potatoes and yams, as also sugar-canes, pine-apples, bananas, and plantains. Orange Island is twenty-two miles long by six broad. Grafton Island is about thirteen miles in circumference, and has good anchorage on the western side, with abundance of very fine water close to the beach. The inhabitants are described by Dampier as short and squat in stature, and of a dark copper colour. Iron was formerly a favourite article of exchange with them, but the use of money is now also understood. The Spaniards took possession of these islands in 1783, being tempted by the gold which is washed down by the mountain torrents, and manufactured by the inhabitants into a thick wire, which they wear as an ornament. The Spanish governor resides at Grafton Island, with about 100 soldiers. These islands are situated between the 20th and 21st degrees of N. Lat.

BASHKIRS, a race, supposed to be descended from the Nogay Tartars, who inhabit the Russian provinces of Ufa and Iekaterinenburg, in the governments of Orenburg and Perm respectively. Little is known of their history previous to their submission to the Russian dominion in the reign of Ivan II. They have frequently attempted to revolt, but have for a long time been faithful in their allegiance to the Russian power, to which, as skilful horsemen and archers, they contribute a useful body of auxiliaries. They are but partially civilized; and, though professing Mahometanism, retain traces of their old superstitions. They have little taste for agriculture, and subsist by hunting and the breeding of cattle and bees. A favourite dish with them is a hash of horse-flesh, which they call *bichbarmark*, or *five-finger-dish*; and they are greatly addicted to an intoxicating beverage called *koumiss*, prepared from fermented mare's and camel's milk. They set so little value on the rich gold mines in their territory, that they are left entirely to the industry of Russian miners, who pay a small rent to the proprietors.

BASIGNANA, a city of Piedmont, province of Alessandria, near the junction of the Po with the Tanaro. It contains 4000 inhabitants. A celebrated treaty of peace was concluded there in 1361, between Duke Otto of Brunswick and Count Galeazzo.

BASIL THE GREAT, one of the most learned and eloquent doctors of the church, was born at Cæsarea in Cappadocia, of a noble Christian family, about the year 328 He went to finish his studies at Athens, where he contracted an intimate friendship with Gregory Nazianzen. He returned in 355 to his native country, and there taught rhetoric for some time. He then travelled into Syria, Palestine, and Egypt, for the purpose of visiting the monasteries of these countries; and finding the monastic life suited to his disposition, he resolved, upon his return, to follow it, and in fact became the first monk and the original founder of monasteries in Pontus and Cappadocia. Upon the death of Eusebius, bishop of Cæsarea, in 370, Basil was chosen his

Basil || Basilic.

successor; but it was with difficulty that he accepted of this dignity; and no sooner had he been raised to it than the Emperor Valens began to persecute him because he refused to embrace the doctrine of the Arians. As soon as this storm had blown over, the new bishop used his utmost endeavours to bring about a re-union between the Eastern and Western Churches, which were then much divided about some points of faith, and also in regard to Meletius and Paulinus, two bishops of Antioch; but all his efforts were ineffectual, and the dispute was not terminated until nine months after his death. Basil had a share in all the controversies of his time regarding the doctrine of the church. He died on the 1st of January 379. The best edition of his works is that of Garnier and Maran, Greek and Latin, 3 vols. fol., Paris, 1721. There is a good recent edition in 4 vols. 8vo, Paris, 1839. Basil's style is pure and elegant, his expressions often reach the sublime, and his thoughts are noble and full of majesty. Erasmus ranks him among the greatest orators of antiquity.

BASIL, *Ocymum basilicum*, a fragrant, aromatic, herbaceous plant, a native of warm climates, and much used to flavour food.

BASIL, in *Joinery*, the sloping edge of a chisel, or of the iron of a plane. The basil is usually made twelve degrees for soft wood, and for hard wood eighteen.

BASILAN, one of the Philippine Isles, S.W. of Mindanao; from which it is separated by the Basilan Strait. It is a fertile island, but is infested by pirates. The village is in Lat. 6. 30. N. Long. 122. 24. E.

BASILEUS, (*βασιλεύς*, *king* or *lord*), a title assumed by the emperors of Constantinople, exclusive of all other princes, to whom they gave the title of *rex*. The title *basileus* was subsequently assumed by other kings, particularly the kings of England; as *Ego Edgar totius Angliæ basileus confirmavi*. Hence also the queen of England was anciently styled *Basilea* or *Basilissa*. See ARCHON, and KING.

BASILIAN MONKS, a religious community of the order of St Basil. That saint, having retired into a desert in the province of Pontus, founded a monastery for the convenience of himself and his numerous followers; and, for the better regulation of this society, he drew up in writing the orders and rules which they were to observe. This new order quickly spread all over the East, and soon passed into the West; and it is even said that before his death Basil saw himself the spiritual father of more than ninety thousand monks in the East alone. The historians of the order state that it produced fourteen popes, many cardinals, and a great number of patriarchs and archbishops, 1805 bishops, 3010 abbots, 11,805 martyrs, with an infinite number of confessors, virgins, &c. It was introduced into the West in 1057, and reformed in 1569 by Pope Gregory XIII., who united the religious of this order in Italy, Spain, and Sicily, into one congregation.

BASILIC, or BASILICA, in the ancient architecture, a kind of public hall or court of judicature, where the princes or magistrates sat to administer justice. This word is taken from the Greek *βασιλική*, a *royal house*, or *palace*.

The basilicæ consisted of a great hall, with aisles, porticoes, tribunes, and tribunals. The bankers, too, had one part of the basilica allotted for their residence; and scholars likewise went thither to pronounce their declamations. In after times the denomination of basilica was also given to other buildings of public use, as town-houses, exchanges, and the like. The Roman basilicæ were covered, by which they were distinguished from the fora, which were public places in the open air. The first basilica at Rome was built by Cato the elder, whence it was called *Porcia;* the second was called *Opimia;* the third was that of Paulus, built at great expense, and with much magnificence, whence it was called by some *regia Pauli;* and Julius Cæsar erected a fourth called *basilica Julia*, of which Vitruvius tells us he had the direction. Besides these there were others, to the number of eighteen or twenty. The basilica Julia not only served for the hearing of causes, but likewise for the reception and audience of foreign ambassadors. It was supported by a hundred marble pillars in four rows, and enriched with decorations of gold and precious stones; and in it were thirteen tribunals or judgment-seats, where the prætors sat for the despatch of judicial business. Basilica.

Basilica is also used by ecclesiastical writers for a church; in which sense the name frequently occurs in St Ambrose, St Austin, St Jerome, Sidonius Apollinaris, and other writers of the fourth and fifth centuries. The name was probably thus applied from many of the ancient churches having been formed out of the Roman halls or basilicæ above described. The name is chiefly applied, in modern times, to churches of royal foundation, as those of St John de Lateran and St Peter of the Vatican at Rome, founded by the Emperor Constantine.

BASILICA, *τὰ Βασιλικά*, in the history of jurisprudence, a name given to a digest of laws commenced by the Emperor Basilius, and completed by his son Leo the philosopher. This collection, according to some, received the title of Basilica in honour of the Emperor Basilius; while others think that it was so denominated from the circumstance of its containing *βασιλικὰς διατάξεις* or imperial constitutions. It was begun by Basilius in the year 867, and completed by Leo in the year 880; the former having carried the work as far as forty books, and the latter having added twenty more, in which state it was published. In 911, Leo was succeeded by his son Constantinus Porphyrogenitus, from whom the Basilica received their final revision, *τὴν τελευτάιαν ἀνακάθαρσιν*; and the amended edition is supposed by Heimbach to have appeared about the year 945. Opinions, however, are divided as to whether the work has descended to us in the state in which it was first published by Leo, or according to the revised and improved edition of Constantine. Brunquell thinks that we possess the Basilica in the amended form; but Hoffmann considers this opinion doubtful, and his suspicions have been confirmed by the subsequent investigations of Heimbach. In the West, the Basilica never obtained the force of law; and the chief value of the collection therefore consists in the illustration it furnishes of the Justinianean body of law from which it was mostly compiled; but in this respect its utility has long been understood and acknowledged. Four complete books of the Basilica, namely, the forty-fifth, forty-sixth, forty-seventh, and forty-eighth, and fragments of two others, the twenty-eighth and twenty-ninth, were published at Paris in 1557, accompanied with a Latin version, by Gentianus Hervetus. In 1566, Cujacius published at Lyons a Latin version of the sixtieth book, which is of great length. All the different portions which had thus been edited were collected by Dionysius Gothofredus, and printed at Hanau in 1598 and 1606. But the more extensive and complete edition of Fabrot, which appeared at Paris in 1647, superseded these imperfect publications, and proved of great service to the study of ancient jurisprudence. It is contained in seven volumes folio, and accompanied with a Latin version of the text as well as of the Greek scholia subjoined. Of the sixty books which composed this great work Fabrot supposes that he has exhibited forty-one in an entire form; but Meerman, Reitz, and others, think that this estimate admits of some abatement. About a century after the date of Fabrot's edition, Reitz published four entire books of the Basilica, namely, the forty-ninth, fiftieth, fifty-first, and fifty-second, which were inserted in the fifth volume of Meerman's *Thesaurus Juris Civilis et Canonici*, and, thirteen years afterwards, given to the world in a separate form, accompanied with the commentaries (as edited by Ruhnken) of Thalelæus, Theodorus, Stephanus, Cyrillus, Gobidas, and other Greek lawyers, on the titles of the Pandects and Code *De Postulando sive de Advocatis, nec non de Procurator-*

Basilicata ‖ Basilisk.

bus et Defensoribus. The ancient *Glossæ*, which are not without their value, were first published by Labbé, and afterwards illustrated by Schulting and Röver.[1]

BASILICATA, a province of the kingdom of Naples, bounded on the N. by Capitanata, N.E. by Terra di Bari, E. by Otranto and the Gulf of Taranto, S. by Calabria Citra, S.W. by the Mediterranean, W. by Principato Citra, and N.W. by Principato Ultra. It has an area of 3130 geographical square miles, and is divided into four districts and 121 communes. Pop. 481,288. In the N.W. part of this territory the Apennines divide into two branches, the one running eastward to Terra di Bari, and the other southward to Calabria. The principal rivers are the Bradano, Basento, Salandrella, Agri, and Sinno, all flowing into the Gulf of Taranto. The principal productions are maize, wine, lint, hemp, and tobacco; swine, goats, and sheep, are numerous; and the produce of the silkworm forms a considerable branch of industry. The chief towns are Potenza, Francavilla, and Tursi.

BASILICI, a denomination given in the Greek empire to those who carried the emperor's orders and commands.

BASILIDIANS, the followers of Basilides of Alexandria, one of the most eminent leaders of the Gnostics, who lived near the beginning of the second century. It has commonly been said that he held the body of Christ to be a mere phantom, and that he gave his form to Simon the Cyrenian, who was crucified in his stead. We learn from Eusebius that Basilides wrote twenty-four books upon the Gospel, of which some fragments are extant, and that he forged several prophets, to two of which he gave the names of *Barcaba* and *Barcoph.* A *Gospel* of Basilides is mentioned by Origen, Ambrose, and Jerome. The Basilidians held much the same opinions with the Valentinians, another branch of the Gnostic family. They asserted that all the actions of men are necessary; that faith is a natural gift, to which men are forcibly determined; and that however irregular or vicious may be their lives, they are nevertheless sure to be saved. Irenæus and others assure us that they acted in perfect consistency with their principles, committing all manner of villanies and impurities, in confidence of their natural election. It however appears that, whatever opinions his followers may have held, Basilides himself recommended purity of life and the practice of piety; and that he supposed the man Jesus and Christ united to constitute the Saviour. (Mosheim, *de Reb. Christ., &c.* pp. 342–361.) The Basilidians believed in a hierarchy of divine persons, or Æons. Under the cabalistical name *Abraxas*, they are believed to have worshipped the supreme God, from whom, as a principle, all other things proceeded. There are still extant gems inscribed with the word *Abraxas*, and which were probably used as amulets against diseases and evil spirits. See ABRAXAS.

BASILISK (βασιλίσκος, from βασιλεύς), a fabulous crested serpent, called a cockatrice, because supposed to be produced from a cock's egg. (See Lucan, ix. 726). It is also the name given by naturalists to a genus of saurian reptiles belonging to the Iguanoid family. See REPTILIA, *Index.*

BASILISK, an ancient species of ordnance, so called from its supposed resemblance to the fabulous serpent of that name. The basilisk threw an iron ball of 200 pounds weight. It was much used in the time of Sultan Solyman, particularly during the wars of Hungary, but is now entirely out of use; unless, indeed, the name may still be applied to those enormous pieces of ordnance which the Turks have built into the ramparts of the castles on the Dardanelles, and which carry stone balls of from 200 to 300 pound weight.

Basilius ‖ Basket.

BASILIUS I., surnamed the *Macedonian*, was sprung of an obscure family in Macedonia, and rose, after many adventures and vicissitudes, from the rank of a common soldier to be emperor of the Greeks. He was made chamberlain to the Emperor Michael III., and having co-operated with that weak and vicious prince in the murder of the Cæsar Bardas, he was made his colleague in the empire. In A.D. 867, he assassinated Michael when overpowered by wine, and thus obtained undivided sovereignty. He ruled with great ability, and left the kingdom in a very flourishing condition. He was dreaded by the Saracens, whom he frequently vanquished; and he was loved by his subjects on account of his justice and clemency. He died in A.D. 886, of wounds received from a stag while hunting. He is the author of a small work on the duties of a prince, which he dedicated to his son. (Gibbon, xlvii. liv.)

BASINGSTOKE, a market and borough town in the county of Hants, 45 miles from London. It occupies a pleasant situation, and has a good trade in corn and malt, which has been greatly facilitated by the canal which joins the rivers Wey and Thames. The church is a spacious and handsome structure. The town is governed by a mayor, four aldermen, and twelve councillors. Pop. in 1851, 4263.

BASKERVILLE, JOHN, an eminent letter-founder and printer, was born in 1706, at Wolverley, in Worcestershire. He was heir to an estate of about L.60 a year, the whole of which income he allowed to his parents during their lives. In his early years he conceived a love for calligraphy and cutting in stone; and being brought up to no particular profession, he became a writing-master at Birmingham when about twenty years of age. Here the improvements made in different manufactures soon drew his attention, and he applied to the business of japanning, which he carried on for a long time with distinguished excellence and success. In 1750 he turned his attention to letter-founding, which, with much labour and expense, he brought to great perfection, and in a few years proceeded to printing. His first work was an edition of Virgil in royal quarto. Soon after this the university of Cambridge granted him permission to print a Bible in royal folio, and editions of the Common Prayer in three sizes; a privilege for which he paid a considerable sum to the university. He afterwards printed Horace, Terence, Catullus, Lucretius, Juvenal, Sallust, and Florus, in royal quarto; Virgil in octavo; and several books in duodecimo. He likewise published some of the English classics. These books are admirable specimens of typography; and indeed Baskerville is deservedly ranked among those who, in modern times, have brought the art of printing to its greatest perfection. It has been observed, however, that his books are far more elegantly than correctly printed. Not having met with that encouragement which he expected from the booksellers, Baskerville set up his letter foundery for sale a little before his death, which took place in July 1775.

BASKET, a utensil made of twigs, rushes, or chips, as well as of a variety of other materials, interwoven together, and used for holding or carrying any commodity. The ancient Britons were noted for their ingenuity in making baskets, which they exported in large quantities. These baskets were of very elegant workmanship, and bore a high price. They are mentioned by Juvenal among the extravagantly expensive furniture of the Roman tables in his time.[2]

---

[1] See a very learned and satisfactory article on the Greek Texts of the Roman Law, in the *Foreign Quarterly Review*, No. xiv. April 1831.

[2] The words of Juvenal are, *Adde et bascaudas et mille escaria*, "Add *baskets*, and a thousand other dishes." That these "baskets" were of British manufacture is evident from the lines of Martial:

"Barba a de *pictis* veni bascauda *Britannis*,
Sed me jam mavult dicere Roma suam."

Basket-making.

BASKET-MAKING. Modern ingenuity has applied many substances before unthought of to the construction of baskets, such as iron and even glass. But wicker-work being the oldest as well as the most universal invention, it alone will be treated of in the present article. The process of interweaving twigs, reeds, or leaves, is seen among the rudest nations of the world; and there is known even an inferior specimen of art among the natives of Van Diemen's Land, consisting of a bunch of rushes tied together at either end, which, spread out in the middle, forms a basket. But the sudden alteration of shape obviously renders this construction less convenient; whence the same and other tribes make a basket of leaves interwoven, and that so skilfully executed, that it retains either milk or water. A bundle of rushes spread out may be compared to the warp of a web, and the application of others across it to the woof, also an early discovery; for basket-making is literally a web of the coarsest materials. By experience these materials are refined and ornamented; and, in the most improved stages of manufacture, neat and useful implements and utensils are produced. Scarcely any nation has been entirely ignorant of the art; and our ancestors in this island made baskets which, as we have already stated, were carried to Rome either for use or ornament.

Basket-making, however, has by no means been confined to the fabrication of those simple and useful utensils from which its name is derived. Of old, the shields of soldiers were fashioned of wicker-work, either plain or covered with hides; and the like has been witnessed among modern savages. In Britain, the wicker boats of the natives, covered with the skins of animals, attracted the notice of the Romans; and Herodotus mentions boats of this kind on the Tigris and Euphrates. But there was this difference, that the former seem to have been of the ordinary figure of a boat, whereas the latter were round and covered with bitumen. Boats of this shape, about seven feet in diameter, are used at the present day on these rivers; and boats of analogous construction are employed in crossing the rivers of India which have not a rapid current. Nothing can be more expeditious or more simple than the fabrication and materials of these vessels, if they merit that name. One may be made by six men in as many hours. Only two substances, almost always accessible, are used,—hides and bamboo. They are navigated either by paddles where the water is deep, or are pushed over a shallow bottom with long poles; and the passengers within are safely transported, being kept dry by planks and pieces of wood at the bottom. The basket-boats on the river Krishna, in the same country, are about twelve feet in diameter and four feet deep. Whole armies are thus enabled to continue their march, and even heavy artillery has been conveyed in this manner across rivers. Sometimes the boats are towed by bullocks fastened to them, and goaded on in the proper direction. In different parts of the world, whole houses, cottages, fences, and gates, are formed of basket or wicker work. On the Continent, a two-horse carriage, called a Holstein waggon, of very considerable size, and fit to carry several persons, is composed solely of basket-work. The same is done in Britain with regard to the bodies of gigs; and an appendage of the stage-coaches is literally designed *the basket;* besides a vast variety of works on a smaller scale.

In respect to the materials employed, besides those specified as belonging to the ruder nations, there are many which are equally the product of nature and art. Twigs, branches, straw, and whalebone, are all of the number. The natives of some parts of South America make baskets simply of rushes, so closely interwoven as to hold water; and thousands of them are annually sold in the Spanish provinces. The Kaffirs and Hottentots are alike skilful with the roots of plants. But of all materials, osiers or willows are in most general use.

Osiers employed for basket-making are either taken entire, cut from the root, split asunder, or stripped of their bark, according to the work to be produced; but in the latter case they are previously soaked in water. The stripping is performed by drawing the willows through an iron-edged implement called brakes, which removes the bark, and the willows are then cleaned, as far as necessary, by manual operation with a sharp knife. Next they are exposed to the sun and air, and afterwards placed in a dry situation. But it is not the less necessary to preserve willows with their bark in the same manner; for nothing can be more injurious than the humidity inherent in the plant; and previous to use they must be soaked some days in water also. The barked or white osier is then divided into bundles or faggots according to size; the larger being reserved to form the strong work in the skeleton of the basket, and the smaller for weaving the bottom and sides. Should the latter be applied to ordinary work, they are taken whole; but for implements of slight and finer texture, each osier is divided into splits and skains; which names denote the different degrees of size to which they are reduced. Splits are osiers cleft into four parts, by means of a particular implement employed for that purpose, consisting of two edge tools placed at right angles, whereby the rod is longitudinally divided down the pith. These are next drawn through an implement resembling the common spoke-shave, keeping the grain of the split next the wood or stock of the shave, while the pith is presented to the edge of the iron, which is set in an oblique direction to the wood: and in order to bring the split into a shape still more regular, it is passed through another implement called an upright, consisting of a flat piece of steel, each end of which is fashioned into a cutting edge, like that of an ordinary chisel. The flat is bent round, so that the two edges approach each other at a greater or less interval by means of regulating screws, and the whole is fixed into a handle. By passing the splits between the two edges they are reduced to skains, the thickness of which is determined by the interval between the edges of the tool. All the implements required by a basket-maker are few and simple: they consist, besides the preceding, of knives, bodkins and drills for boring, leads for keeping the work steady while in process, and, where it is of small dimensions, a heavy piece of iron called a beater, which is employed to beat the basket close as it is augmented. Thus a basket-maker has this great advantage over many other artificers, that he can establish himself in his profession at the most inconsiderable expense either for tools or materials.

An ordinary basket is made by preparing the requisite number of osiers, and preserving their length considerably greater than that of the finished work. They are ranged in pairs on the floor parallel to each other, at small intervals, in the direction of the longer diameter of the basket; and this may be called the woof; for, as we have said, basket-work is literally a web. These parallel rods are then crossed at right angles by two of the largest osiers, with the thick ends towards the workman, who places his foot upon them; and weaving each alternately over and under the parallel pieces first laid down, they are by that means confined in their places. The whole now forms what is technically called the slat or slate, which is the foundation of the basket. Next, the long end of one of the two rods is taken and woven under and over the pairs of short ends all round the bottom, until the whole be woven in. The same is done with the other rod, and then additional long osiers are also woven in, until the bottom be of sufficient size, and the woof be occupied by them. Thus the bottom or foundation on which the superstructure is to be raised is finished; and this latter part is accomplished by sharpening the large ends of as many long and stout osiers as may be necessary to form the ribs or skeleton. These are forced or plaited between the rods of the bottom from the edge towards the centre, and are turned up in the direction of the sides; then other rods are woven in and out between each of them, until the

Basket-making.

basket is raised to the intended height, or, more correctly speaking, the depth it is to receive. The edge or brim is finished by turning down the perpendicular ends of the ribs, now protruding and standing up over each other, whereby the whole is firmly and compactly united. A handle is adapted to the work by forcing two or three osiers, sharpened at the end, and cut to the requisite length, down the weaving of the sides, close together; and they are pinned fast, about two inches from the brim, in order that the handle, when completed, may be retained in its proper position. The osiers are then either bound or plaited in such fashion as pleases the taste of the artist.

This is the most simple kind of basket, from which others differ only in finer materials and nicer execution; but in these there is considerable scope for taste and fancy, and implements are produced of extreme neatness and ingenuity in construction. Some are formed of twigs or straw entire; others of sections, split of various thickness, coloured, plaited, or plain; and baskets of endless variety in size, figure, and texture, are fabricated according to the artist's inclination. The skains are frequently smoked and dyed either of dull or brilliant colours, and by intermixing them judiciously a very good effect is produced.

From the simplicity of this manufacture, a great many individuals, independent of professed basket-makers, are occupied in it; and, fortunately, it affords employment to the blind in the several asylums established for their reception. Not that persons suffering privation of sight are incapable of more ingenious and delicate mechanical exercises, but the facility of teaching and acquiring the principles of basket-making being alike obvious, is one of the strongest recommendations in its favour. At Liverpool, where there is an asylum of this description, the art is practised with success; and in the city of Edinburgh a number of the blind find employment of the same kind in the asylum established there.

The best materials for basket-making have been principally imported into Great Britain from France and Holland; but the duration of the late war induced the inhabitants of this country to endeavour to obtain a supply at home. Cultivation of the osier was imperfectly understood in England, and in Scotland it scarcely received any attention whatever; whence, as a suitable encouragement, that patriotic society whose notice is specially directed to the improvement of arts and manufactures, offered premiums to those cultivators who should raise the greatest quantity, not being less than 6000 plants on an acre.

It became an object with such cultivators to ascertain, not only the quantity that could be obtained, but the quality of the produce; which was of the greater consequence, as many plants, passing under the general name of osiers, and even possessing their external characters, are ill adapted for the work intended. But considerable light has been thrown on the subject by Mr Philipps of Ely, who was early rewarded by a premium on account of the utility of his observations. He remarks that the osier is a species of salix, of which there are many varieties; and that these may be comprehended under two classes, the first containing nine or ten species. None, however, excepting one, the gray or brindled osier, is of use. This, in common with the others, has a light-coloured leaf, but is distinguished by the bark being streaked with red or blood colour; and it is of late introduction into Britain, having been first planted in the isle of Ely, where the observer's experiments seem to have been chiefly made. It grows vigorously, is very hardy and tough, and bleaches well. All the others of the same class prefer a wet soil, where they grow quickly and large, flourishing even in the most barren kind of peat; but they are coarse and spongy, have a thick pith, and are extremely perishable. Nevertheless they are sometimes used for coarser workmanship, and are profitable to those who live in the vicinity of places where there is a great demand for osiers, and cheap conveyance. During the interruption of Continental intercourse they were much resorted to by basket-makers: but their inferiority has brought the English baskets into disrepute in foreign markets. The second class, according to Mr Philipps, contains four or five different species. One of these, the Welsh willow, is very tough and durable, but not of a favourable colour. There are two varieties, red and white, the former of which is preferred, and forms part of every plantation, from its particular utility in tying up the bundles of willows after they have been barked or whitened. The bitterness of this plant is such as to be a protection from the depredations of cattle. Besides these there are the west country Spaniard, the new willow, the French, and the red Kent willow. The first has been superseded by others of superior quality; but experience proves that an acre will carry 2000 plants more of them than of some which are in higher repute. But the most esteemed of all is the French willow, especially as being most adapted for smaller and finer work in baskets, fans, hats, and other light articles. It is rather of slow growth, but extremely taper, pliant, close-grained, tough, and durable. Great quantities of it are always imported from the Continent, its culture being more neglected here than that of the others; however, it must be distinguished from a species resembling it, which is characterized by the brittleness of the leaves, which snap like glass when drawn through the fingers. Plantations of the French willow have been strongly recommended as forming a useful commodity, and being always in demand. Having attained the requisite maturity, all willows are cut down and made up into bunches in iron hoops 36 or 40 inches in diameter, for the manufacturers, and are sold either in this way or in loads, the price being subject to fluctuation according to the scarcity or abundance of the commodity.

Basket-making.

In regard to the cultivation of osiers very different opinions prevail; originating, it is probable, from too limited experiments, combined with the diversity of soil and climate. Mr Philipps, whose opinions are entitled to attention, conceives that autumn, and not spring, is the most proper season for planting willows: the stagnation of the juices he considers the true criterion whereby to regulate the period, but not on account of the set so much as on account of the trunk; for if the shoot be severed when the sap is in circulation, the parent plant bleeds to death. The osiers which he planted in the first week of October he found to have struck roots about Christmas, though there was no external sign of vegetation. In prosecuting this subject Mr Philipps observes, that he made a plantation in autumn, and filled up part of the ground which was vacant, in the following month of March, with additional sets. The latter were the further advanced in May, but in June the autumn plants had the advantage, and continued growing well, while many of the others died. In summer, he remarks, "when the fibres have been formed before the winter, or when a tendency to form them has been observed by the swelling of the bark, and particularly at the eye, the plant is enabled to charge itself with a sufficient portion of the juices to answer the demand of spring." Therefore he concludes that the proper rule is to plant as early in autumn as the shoots may be cut, without injuring the parent stock. The cultivator lays out the ground in beds or burrows eighteen feet broad, digging ditches nine feet wide on each side. The upper surface of the ditches, to the depth of fourteen inches, is thrown on the beds, and the remainder of what is excavated from them is used for turf or fuel. The beds, now consisting of about two feet and a half thick of solid earth above the surface of the substratum of peat, are planted in the following autumn, and produce good crops.

Experiments have been made by various cultivators respecting the suitableness of different soils, after having borne different kinds of grain. Mr Sheriff has related a profitable mode of culture practised by him in Scotland, and also made

Basket-making.

some judicious observations on the subject in general. He remarks that the finest and most valuable twigs can be procured only from land cured of chilling weeping springs; and if the soil is not of considerable thickness, it must be rendered so by manure. Moderate moisture is favourable to the production of fine twigs, but water constantly stagnant is ruinous. He proposes to make the cuts or shoots from fifteen to seventeen inches in length, and to allow four or five inches to remain above ground, to be cut down by the surface of the soil, when the heads of the stocks shall, in a series of years, have become too bushy. By this operation the vigour of the plant is renewed in the most decided manner. Mr Sheriff forgets, however, that, in the time he mentions, a much greater protrusion from the earth will have taken place by the simple vegetation of the plant than is necessary to leave room for cutting off the head. It is necessary, in his opinion, to trim and dress the stocks from decayed wood, and to retain only as many buds on each as the plant may be expected to bring to perfection in length and strength of shoot. Thus the superabundant stumps of old wood are cut down, and the weakest shoots extirpated, in November and December, or March and April; and seldom more than two buds should be left on those selected to stand and produce the next summer's growth. He considers the leading errors of those who have attempted the cultivation of osiers to consist in employing improper soil, peat-earth perhaps, or poor bogs; and also in defective preparation of the soil, though suitable in other respects. Failure may, besides, arise from planting bad or useless species of osiers; putting too few cuts in the ground; neglecting their subsequent culture, particularly during the first spring and summer after plantation; and allowing the shoots to be cut down after Christmas and before the middle of March, which renders the stocks liable to be much weakened by hard frosts succeeding heavy rains, immediately after the twigs have been cut, and before the wounds from the knife have healed. By pursuing a system analogous to what is here exposed, he calculates the profits of an acre of osiers at about L.18, 10s.; and he mentions that he contracted to receive a sum between L.220 and L.250 for the produce of twelve statute acres and a half. It does not appear, however, that this was an annual crop, and it is rather to be inferred that willows of several years' growth formed part of it. Mr Sheriff's experiments and observations were rewarded with the gold medal of the Society for the Encouragement of Arts and Manufactures. Another cultivator, Mr Wade, calculated his profits on fourteen acres, which were planted with 12,000 sets each, at intervals of twenty-six inches by ten, as amounting to L.10 per acre.

Among the experiments on the quality of soil may be instanced a plantation made in spring, of large cuttings, eighteen inches long, thrust so far into the earth as to leave four or five inches protruding. Part of the ground had been in wheat after summer fallow, and part, which was also planted, had been sown with grass seeds. The plants made a more vigorous shoot in spring than at any subsequent period, and of the whole but few failed. Those which succeeded the wheat produced the best osiers, and those which were planted among the grass seeds the worst. Both stood on a strong clay soil; and from the difference seen here, it has been concluded, that, as the cleanest ground produced the best crop, summer fallowing would be advantageous. Another example is given, where, of 350 sets planted in garden ground, the soil of which was clay, 341 succeeded; producing, in the first year apparently, a bundle thirty-eight inches in circumference, and some of the osiers above ten feet long. They were planted in the latter end of March, and arranged in rows, between which was sown a crop of beans. Both the interval separating the plants and their age are arbitrary, as is also the extent of the plantation, and we may likewise add the quality of the soil; for experiments have not been made on a sufficient scale to determine the fact. The most superficial observer cannot fail to have remarked the comparative slenderness of all plants crowded together, and the superior strength of those apart from each other. The sets of osiers, for several reasons, should be inserted in regular rows. Their age does not appear important, and nowhere is a more vigorous crop produced than from the root of the oldest tree deprived of its trunk. In general, previous preparation of the ground is profitable; and plantations may thence be formed, which are to be annually cut down for baskets and such light utensils; but the shoot is allowed to grow two, or even four years, if strong rods are required for larger and coarser workmanship. The rapidity and certainty with which this plant vegetates preserves it in a manner under absolute control, and peculiarly adapts it for a variety of mechanical purposes. Many cultivators recommend deep insertion of the shoot into the ground; but here there is a limitation; for if it be too deeply inserted, the vegetation will be less vigorous. At the same time, the powerful tendency to vegetation in a willow is rather an exception to ordinary rules; and although the lower part be injured, roots may spring nearer the surface. But it is not to be overlooked, that if a tree be transplanted into too deep a pit, the root, instead of striking out new fibres, remains inactive, and the tree withers and decays; or if seeds be deposited too deeply in the earth, no vegetation will ensue; whereas, even those on the surface will put forth a radicle, and establish themselves there. In the former case, they either lose the germinative faculty, or are destroyed; but if a tree be transplanted into a shallow pit the root will spread, and the whole will exhibit a luxuriant vegetation. These are facts which demand greater attention than they usually receive; and the depth at which the shoots of osiers are inserted should be carefully observed. Nevertheless we must repeat, that it does appear that deep insertion is not as noxious to them as to other plants.

It was long supposed that willows flourish nowhere but with abundance of water. Undoubtedly, adequate humidity is very essential; but this general position was quite erroneous, as experiment and observation daily testify. Willows growing in water have almost invariably a sickly aspect; few strong or healthy scions spring from them; and their vegetation is never so vigorous as when they are at some distance from it. Every plant has a predilection for a particular place, where the conditions of its aliment and vegetation concur. The willow requires a considerable degree of humidity, though it may also be seen vigorous on drier soils; but the vicinity of water is an essential quality in selecting a suitable spot for a plantation. The purposes to which the plants are to be applied must be considered, and the circumstances of their growth so regulated that they may become suitable for the object in view. There is little doubt that, with due notice and consideration, this plant may receive great amelioration by culture.

All plantations must be well fenced against cattle, as the willow, both shoot and leaf, is with them a favourite kind of food; and as at certain seasons of the year some particular caterpillars infest the plant, stripping it totally bare and injuring its vegetation, care should also be taken to remove them as effectually as possible. (J. G. D.)

Baskets of Earth || Basnage.

Baskets of Earth, called in French *corbeilles*, are sometimes placed on the parapet of a trench, to form a sort of epaulement or breastwork, between which the soldiers fire upon the enemy.

BASKING SHARK, a very large and powerful but harmless species of shark. See Ichthyology, *Selache*.

BASNAGE, Jacques, a learned author, and pastor of the Walloon church at the Hague, was born at Rouen in Normandy on the 8th of August 1653. He was the son of Henri Basnage, one of the ablest advocates in the parliament of Normandy. At the age of seventeen, having made

himself master of the Greek and Latin authors, as well as of the English, Spanish, and Italian languages, he went to Geneva, where he began his theological studies under Mestrezat, Turretin, and Tronchin; and completed them at Sedan, under the professors Jurieu and Le Blanc de Beaulieu. He then returned to Rouen, where he was received as minister in September 1676; and in this capacity he remained till the year 1685, when the exercise of the Protestant religion being suppressed at Rouen, he obtained leave of the king to retire to Holland. He settled at Rotterdam, and continued a minister pensionary there till 1691, when he was chosen pastor of the Walloon church of that city. In 1709, the pensionary Heinsius got him elected one of the pastors of the Walloon church at the Hague, intending to employ him not only in religious but also in civil affairs. Accordingly he was engaged in a secret negotiation with Marshal d'Uxelles, plenipotentiary of France at the congress of Utrecht; a service which he executed with so much success, that he was afterwards intrusted with several important commissions, all of which he discharged in such a manner as to establish a high character for ability and address. Indeed, a celebrated modern writer has said of him, that he was fitter to be a minister of state than the minister of a parish. The Abbé Dubois, who was sent to the Hague in 1716, as ambassador plenipotentiary from His Most Christian Majesty, in order to negotiate a defensive alliance between France, England, and the States General, received instructions from the Duke of Orleans, then regent of France, to address himself to M. Basnage, and to follow his advice: they accordingly acted in concert, and the alliance was concluded in January 1717. His published works, which are mostly in French, spread his reputation over the greater part of Europe. Among these are, *The History of the Religion of the Reformed Churches; Jewish Antiquities; The History of the Old and New Testament; Dissertation on Duels, &c.* He died on the 22d September 1723.

Basnage, *Henri, Sieur de Beauval*, was the second son of Henri Basnage, and brother of the preceding. He studied the law, and was admitted an advocate in the parliament of Rouen in 1679. He practised with great reputation, till the revocation of the edict of Nantes obliged him to fly to Holland, where he composed the greater part of his works. He died in 1710, aged fifty-four. His chief work is his *Histoire des Ouvrages des Sçavans*, Rotterdam, 24 vols. 12mo.

BASON, or Basin, in *Hydraulics*, a reservoir of water, used for various purposes.

BASQUE Language. The language spoken by the Spaniards in what are called the Basque provinces, as also in Navarre. The people call it *Escuara*. For a long time it was supposed to be a dialect of the Celtic; but later researches show that there is good ground for considering it as a distinct ancient language, and as having been once spoken over all the Peninsula. This is proved by the ancient names of mountains, towns, and rivers being decidedly derived from Basque radicals; as is shown in the curious *Inquiries* of William Von Humboldt, published at Berlin in 1821; and by the dictionary and grammar of this tongue recently published. The structure of the verb is complex—it is considered as having 11 moods and 46 tenses; so as to exhibit all the relations of the agent to the action, and to the object it affects. The substantive has no distinction of gender; the articles are two, *a* for the singular, and *ac* for the plural; the cases are marked by affixes or prepositions. In the structure of the sentences the noun occupies the first place; it is followed by the article, then the adjective, next the adverb, the verb, the thing acted upon, and lastly the affix.

Basque *Provinces* (*Provincias Vascongadas*). The three Spanish provinces known by this name, which are distinguished from all the other divisions of Spain by the character, language, and manners of the inhabitants, and by the enjoyment of political privileges which make the form of their government nearly republican, are Biscay (Vizcaya), Guipúzcoa, and Alava. The territory occupied by them is in the form of a triangle, bounded on the N. by the Bay of Biscay, S. by Soria, E. by Navarra and part of France, and W. by Santander and Burgos. It comprises an area of 2958 square miles; pop. in 1849, 373,149. These three provinces are more particularly described under their respective heads. The ancient French Basque provinces now form the arrondissements of Bayonne and Mauleon.

BASS, or Base, in *Music*, means, in a general sense, the lowest part in a composition for two or more voices or instruments, or for an organ or pianoforte, &c. A fundamental bass is that in which each note bears a direct harmony only, *i. e.*, a common chord or a chord of the seventh. A thorough bass (*Basso continuo* in Italian), or continuous bass, is that which, on the organ or pianoforte, accompanies a musical composition throughout, and of which the harmony played by the right hand consists of a judicious selection of chords drawn from the upper parts of the composition. (See Music, §§ *Harmony, Organ, Pianoforte;* and *Accompaniment*, in appendix to Music.) (G. F. G.)

Bass Rock, an islet about a mile in circumference, situated on the coast of East Lothian, near the entrance of the Firth of Forth, and at a short distance from the town of North Berwick. It is steep and inaccessible on all sides, except to the south; and even there it is with some difficulty that a single person can ascend. In ancient times it belonged to the Lauders; and although long solicited by royalty, it was not acquired till 1671, when Charles II. purchased it. Its insulated situation and inaccessible nature soon suggested the idea of a state prison, which was accordingly erected in the reign of Charles, or in that of his brother James, together with some trifling fortifications. It was here that some of the Covenanters were confined, who had been found in arms against the king. At the revolution a party of King James's adherents got possession of the Bass. There being a fountain sufficient to supply water on its summit, with pasturage for the maintenance of a few sheep, and a small rabbit-warren, they were enabled to hold possession, carrying on their piratical operations by means of a boat, which they hoisted upon the rock, out of the reach of attack, and let down at pleasure. This party captured a great many vessels, and held out for King James long after the whole of Great Britain had submitted. Their boat, however, was at last seized or lost, upon which they were obliged to surrender for want of provisions. After this the island was dismantled of its fortifications. It is now the property of Sir Hew Dalrymple Hamilton of North Berwick. There is a cavern which runs quite through the rock, and is accessible at low water, affording refuge for a multitude of wild pigeons. The sea-fowl, which resort to this spot during the breeding season, nearly cover its sides and a large portion of its surface. Of these the gannet or solan goose is the principal; with puffins, cormorants, and kittywakes. The island is farmed at a considerable rent for the sake of the birds and eggs, which are brought to market. The rock consists of greenstone and trap tuffa. Long. 2. 37. W. Lat. 56. 4. N. (See *The Bass Rock, its Civic and Ecclesiastical History*, Edin. 1848.)

Bass's Straits, the channel which separates New Holland from Van Diemen's Land. It is nearly fifty leagues in length from E. to W., and about the same breadth from N. to S. The navigation of this strait is rendered dangerous in some parts by groups of barren and unproductive islands, scattered through it. Van Diemen's Land was supposed by all the earlier navigators to form a part of New Holland; until Mr Bass, the surgeon of a man-of-war, conceived that there were indications of a channel. This conjecture was found to be correct; and the channel has since borne his name.

Bass-Viol, a large old instrument of the violin family,

Bassani & Bassein.

with six strings and a fretted finger-board; long since superseded by the violoncello.

BASSANI, Giovanni Battista, maestro di cappella of the cathedral church of Bologna, was born at Padua about the year 1657. His works, which are very voluminous, consist of psalms, masses, motets with instrumental parts, and sonatas for the violin; on which last-mentioned instrument he was an admirable performer. It is said that he was the instructor of Corelli. His fifth opera, in particular, containing twelve sonatas for two violins and a bass, is written in a style wonderfully grave and pathetic, and abounding with evidences of great learning and fine invention. The first and third operas of Corelli are apparently modelled after this work. Bassani was one of the first who composed motets for a single voice, with accompaniments of violins; a practice which is liable to objection, as it assimilates church-music too nearly to that of the chamber.

BASSANO, Giacomo da Ponte, a celebrated Venetian painter, born in 1510. His subjects were generally peasants and villagers, cattle, landscapes, with some portraits and historical designs. His figures are well designed, and his animals and landscapes have an agreeable air of simple nature. His compositions, though devoid of much elegance or grandeur, have abundance of force and truth: the local colours are well observed, the carnations are fresh and brilliant, and his chiaroscuro and perspective are unexceptionable. He finished a great number of pictures; but notwithstanding his application, his genuine works are rare; many of those which are called originals being either copies by the sons of Bassano, or others. His true pictures, when undamaged, always bear a considerable price. He died in 1592, aged eighty-two. Francesco and Leandro, his sons, made some progress in the same art; but inheriting a species of lunacy from their mother, both came to an untimely end.

Bassano, a city in the Austrian kingdom of Venetian Lombardy, in the delegation of Vicenza. It stands on the river Brenta, over which there is a bridge 180 feet in length. It is surrounded with walls, and has six gates, one of which, built by Palladio, is very much admired. It contains 30 churches with some fine paintings, several religious houses, and other public edifices. Pop. about 12,000. It has extensive silk mills, besides manufactures of cloth, paper, straw hats, copper ware, &c.; and the printing establishment of S. Remondini employs about 1000 persons.

BASSANTIN, James, a Scotch astronomer, son of the Laird of Bassantin, in Teviotdale, was born in the reign of James IV. Educated at the university of Glasgow, he travelled through Germany and Italy, and then fixed his abode in the university of Paris, where he taught mathematics with great applause. Having acquired some fortune in this occupation, he returned in 1562 to Scotland, where he died in the year 1568. From his writings he appears to have been no contemptible astronomer, considering the times; but, like most of the mathematicians of that age, he was not a little addicted to judicial astrology. His works are, 1. *Astronomia Jacobi Bassantini Scoti, opus absolutissimum, &c., ter editum Latine et Gallice.* Genev. 1599, folio. This is the title given it by Tornæsius, who translated it into Latin from the French, in which language it was first published. 2. *Paraphrase de l'Astrolabe, avec un amplification de l'usage de l'Astrolabe.* Lyons, 1555. Paris, 1617, 8vo. 3. *Mathematica Genethliaca.* 4. *Arithmetica.* 5. *Musica secundum Platonem.* 6. *De Mathesi in genere.*

BASSE Terre, capital of the island of St Christopher, one of the Caribbee Islands. See Christopher's Island, St.

BASSEIN, a town in the Burmese territory, formerly included within the possessions of the sovereign of Ava, but now belonging to the British. It is the chief place of a district of the same name, and forms part of the province or kingdom (for such it once was) of Pegu, recently incorporated by the British Government with the dominions under its administration. Bassein is seated on one of the channels by which the great river Irawaddy finds its way to the sea; which from its divergence down to the town, is called Bassein River, and subsequently the Negrais. In the first war with Burmah (carried on under the government of Lord Amherst), this place was taken without opposition; the governor having abandoned the town and burnt it on the approach of the British force. In 1852 its capture was again sought and was obtained, but not without a struggle. On the 17th May in that year, a military force of between 700 and 800 men, with some seamen of one of H. M. ships, embarked on board several steamers at Rangoon, and proceeded up the river to Bassein, abreast of which place the squadron anchored on the 19th. The assailants were landed forthwith; a pagoda was immediately carried; a strong mud fort was then gallantly stormed, and a stockade on the opposite side of the river was simultaneously attacked with success. The loss of the British was not great: that of the enemy was believed to be considerable.

Basset.

The port of Bassein is stated to have a greater depth of water than that of Rangoon; but it is not considered to be so advantageously situated for trade; and intercourse with the northern portion of the Burmese territories by water can be maintained during only part of the year. Lat. 16. 45. Long. 94. 50. (E. T.)

BASSET, or Basette, a game with cards, said to have been invented by a noble Venetian, who was banished for his invention. It was first introduced into France by Signior Justiniani, the Venetian ambassador, in 1674. Severe laws were made against it by Louis XIV., to elude which they disguised basset under the name of *pour et contre*, which occasioned new *arrêts* and prohibitions of parliament.

The parties concerned in this game are a dealer or banker; his assistant, who supervises the losing cards; and the punter, or any one who plays against the banker. Besides these, there are other terms used in this game. 1. The *fasse* or *face* is the first card turned up by the tailleur belonging to the pack, by which he gains the value of half the money laid down on every card of that sort by the punters. 2. The *couch* is the first money which every punter puts on each card; each person who plays having a book of thirteen several cards before him, on which he may lay his money, more or less, at discretion. 3. The *paroli* is, when a punter, having won the first stake, and having a mind to pursue his good fortune, crooks the corner of his card, and lets his prize lie, aiming at a *sept et le va.* 4. The *masse* is, when having won the first stake, the punter is willing to venture more money on the same card. 5. The *pay* is, when the punter, having won the first stake, be it a shilling, half-crown, guinea, or whatever he laid down on his card, and not caring to hazard the paroli, leaves off, or *goes the pay;* in which case, if the card turn up wrong, he loses nothing, having won the couch before; whereas if it turn right, he by this adventure wins double the money staked. 6. The *alpiew* is much the same with paroli, and is used when a couch is won by turning up or crooking the corner of the winning card. 7. *Sept et le va* is the first great chance or prize, when the punter, having won the couch, makes a paroli, and goes on to a second chance, so that if his winning card turns up again, it comes to *sept et le va*, which is seven times as much as he laid down on his card. 8. *Quinze et le va* is the next higher prize, when the punter, having won the former, is resolved to push his fortune, and lay his money a second time on the same card, by crooking another corner; in which case, if it comes up he wins fifteen times the money he laid down. 9. *Trent et le va* is the next higher prize, when the punter, crooking the fourth corner of his winning card, if it turn up, wins thirty-three times the money he first staked. 10. *Soixant et le va* is the highest prize, and entitles the winner to sixty-seven times his first money, which, if it be considerable, may chance to break

Basset-horn || Bassi.

the bank; but the bank has many chances of first breaking the punter. This cannot be won but by the tailleur's dealing the cards over again.

The rules of the game of basset are as follow: 1. The banker holds a pack of fifty-two cards, and having shuffled them, he turns the whole pack at once, so as to discover the last card; after which he lays down all the cards by couples. 2. The punter has his book of thirteen cards in his hand, from the king to the ace, and out of these he takes one card or more at pleasure, upon which he lays a stake. 3. The punter may, at his choice, either lay down his stake before the pack is turned, or immediately after it is turned, or after any number of couples are down. 4. Supposing the punter to lay down his stake after the pack is turned, and calling 1, 2, 3, 4, 5, &c., the places of those cards which follow the card in view, either immediately after the pack is turned or after any number of couples are drawn; then, 5. If the card upon which the punter has laid a stake come out in any even place except the first, he wins a stake equal to his own. 6. If the card upon which the punter has laid a stake come out in any even place except the second, he loses his stake. 7. If the card of the punter come out in the first place, he neither wins nor loses, but takes his own stake again. 8. If the card of the punter come out in the second place, he does not lose his whole stake, but only one-half; and this is the case in which the punter is said to be *faced*. 9. When the punter chooses to come in after any number of couples are down, if his card happen to be but once in the pack, and is the last of all, there is an exception from the general rule; for, although it comes out in an odd place, which should entitle him to win a stake equal to his own, yet he neither wins nor loses from that circumstance, but takes back his own stake.

This game has been the object of mathematical calculation; and M. de Moivre solves this problem: To estimate at basset the loss of the punter under any circumstance of cards remaining in the stock when he lays his stake, and of any number of times that his card is repeated in the stock. From the solution he has formed a table showing the several losses of the punter in whatsoever circumstances he may happen to be. From this table it appears, 1. That the fewer the cards in the stock, the greater is the loss of the punter: 2. That the least loss of the punter, under the same circumstances of cards remaining in the stock, is when his card is but twice in it; the next greater when but three times; the next greater when four times; and the greatest of all when but once. The gain of the banker upon all the money adventured at basset is 15s. 3d. per cent.

BASSET-HORN. See MUSIC, § *Musical Instruments*.

BASSET, *Peter*, a gentleman of good family, chamberlain to King Henry V., whom he attended in his campaigns. He wrote *Acta Regis Henrici V.*, which is said to exist in MS. in the Heralds' College.

BASSETING, in the coal mines, denotes the rise of the vein of coal towards the surface of the earth. This is also called by the workmen *cropping*; and stands opposed to *dipping*.

BASSI, LAURA MARIA CATERINA, an Italian lady eminently distinguished for her learning and her virtues, was born at Bologna in 1711. On account of her extraordinary attainments she received a doctor's degree, and was appointed professor in the philosophical college, where she delivered public lectures on experimental philosophy till the time of her death. In 1738 she married Giuseppe Verrati, a physician, and left several children. She died in 1778.

Bassia || Bastard.

BASSIA, a genus of plants of the nat. ord. of Sapoteæ. The species are found in India and Africa. *B. Butyracea* is a tree of 50 feet in height, found in the Almorah hills in India. The seeds afford a concrete oil of considerable economic importance. *B. longifolia* is also a considerable tree, the seeds of which yield a valuable oil for lamps, soap, and in the kitchens of the poor a seasoning for rice. *B. latifolia* yields a greenish oil coarser than the last; and its flowers on distillation yield an ardent spirit. The wood of all the species is hard and durable.

BASSO-RILIEVO, or BAS-RELIEF, a piece of sculpture where the figures or images do not protuberate or stand out much above the plane on which they are formed. When cut, stamped, or otherwise wrought, so that not the entire body, but only part of it, is raised above the plane, it is said to be done in *relief* or *rilievo*; and when the work is flat, or little raised, it is called *low relief*. If a piece of sculpture, a coin, or a medal, has its figure raised so as to be well distinguished, it is said to be in *bold*, *strong*, or *high* relief, *alto-rilievo*.

BASSOON. See MUSIC, § *Musical Instruments*.

BASSORA. See BUSSORAH.

BASSUS. See ENTOMOLOGY.

BASTARD, *bastardus* (fancifully derived from the Greek *βασσάρα*, *meretrix*, but with more reason from the British *bastærd*, *nothus*, *spurious*, or from the German *bastart*, composed of *bas*, low, and *start*, risen, Saxon *steort*, an upstart, *homo novus*), one whose father and mother were not lawfully married previous to his or her birth, or, as it has sometimes been loosely expressed, one born out of lawful wedlock.

The civil and canon laws do not allow a child to remain a bastard if the parents afterwards intermarry; and this is also the law of Scotland, in which the principle of legitimation by subsequent marriage has been often and solemnly recognized. But herein they differ most materially from the English law; which, though not so strict as to require that a child shall be begotten, yet makes it an indispensable condition that it shall be born after lawful wedlock. Blackstone thinks that the reason of the English law is in this respect much superior to that of the Roman or of the derivative systems, if the principal end and design of establishing the contract of marriage, taken in a civil light, be considered; but this opinion, however natural in an English lawyer, does not seem to be borne out by considerations either of principle or of expediency. For although the learned commentator may be perfectly correct in his estimate of the motives which actuated the parliament of Merton A.D. 1235, when they refused to enact that children born in bastardy should be legitimated by the subsequent marriage of their parents; yet the question still remains whether such an enactment would not have been highly beneficial on grounds of public policy, as well as for the protection of private morals, and whether the experience since acquired has not decided in its favour; points concerning which lawyers, in Scotland at least, have long ceased to entertain any doubt.

Be this, however, as it may, one thing is certain, that all children born before matrimony are bastards by our law; and so are all children born so long after the death of the husband, that by the usual course of gestation, they could not be begotten by him. But this being a matter of some uncertainty, the law is not exact as to a few days; and although the child is born some time after the usual period of forty weeks, this only affords presumption, not proof, of illegitimacy.[1] But if a man dies, and his widow soon after

[1] According to information furnished by the late celebrated anatomist Dr John Hunter, it appears, 1*st*, That the usual period of gestation is nine calendar months, or from 270 to 280 days; but there is very commonly a difference of one, two, or three weeks. 2*dly*, That a child may be born alive at any time three months after conception, but none are born with powers of being reared or attaining manhood before seven calendar months or thereby. 3*dly*, That he, Dr Hunter, had known a woman bear a living child, in a perfectly natural way, fourteen days beyond the completion of nine calendar months; and he believed that two women had each been delivered of a living child, in a natural way, above ten calendar months from the hour of conception. It is owing to these natural irregularities that the law has been obliged to admit of considerable latitude in the application of the ordinary rule.

Bastard. marries again, and a child is born within such a time as that by the course of nature it might have been the child of either husband, in this case he is said to be more than ordinarily legitimate, for when he arrives at years of discretion, he may choose which of the fathers he pleases. To prevent this, among other inconveniences, however, the civil law ordained that no widow should marry *infrà*, or more classically *intrà*, *annum luctus*; a rule which obtained as early as the reign of Augustus, if not of Romulus himself; and the same constitution was probably handed down to our early ancestors from the Romans, during their stay in this island, since we find it established under both the Saxon and the Danish governments.

But as bastards may be born before the coverture or marriage state is begun, or after it is determined, so also children born during wedlock may in some circumstances be bastards; as if the husband be out of the kingdom of England, or, as the law loosely phrases it, *extra quatuor maria*, for above nine months, so that no access to his wife can be presumed, her issue during that period is to be accounted bastard. But generally during the coverture, access of the husband is presumed, unless the contrary be shown; which is such a negative as can only be proved by showing him to be elsewhere; for the general rule is, *præsumitur pro legitimatione*.

The law of adulterine bastardy was recently commented on by the late Lord Langdale, Master of the Rolls, in the case of *Hargrave* v. *Hargrave*, 9 Beavan's *Reports*, 555. His lordship observes:—"A child born of a married woman is, in the first instance, presumed to be legitimate. The presumption established by law is not to be rebutted by circumstances which only create doubt and suspicion; but it may be wholly removed by proper evidence, showing that the husband was, 1. Incompetent; 2. Entirely absent, so as to have no intercourse or communication of any kind with the mother; 3. Entirely absent at the period during which the child must, in the course of nature, have been begotten; or, 4. Only present under such circumstances as afford clear and satisfactory proof that there was no sexual intercourse. Such evidence as this puts an end to the question, and establishes the illegitimacy of the child of a married woman. It is, however, very difficult to conclude against the legitimacy, in cases where there is no disability, and where some society or communication is continued between husband and wife during the time in question, so as to have afforded opportunities of sexual intercourse; and in cases where such opportunities have occurred, and in which any one of two or more men may have been the father, whatever probabilities exist, no evidence can be admitted to show that any man other than the husband may have been, or probably was, the father of the wife's child. Throughout the investigation, the presumption in favour of the legitimacy is to have its weight and influence, and the evidence against it ought, as it has been justly said, to be strong, distinct, satisfactory, and conclusive."

In a divorce *a mensa et toro*, if the wife have children they are bastards, because the law presumes the husband and wife to live conformably to the sentence of separation, unless access be proved; but in a voluntary separation, by agreement, the law supposes access, unless the negative be shown. If a man or woman marry a second wife or husband, the first being living, and have issue by such second wife or husband, the issue is spurious. Again, if a man have issue a son by a woman before marriage, and afterwards marry the same woman and have issue a second son born after the marriage; the first of these, who would be legitimated *per subsequens matrimonium* in Scotland, is termed in England a *bastard eigné*, and, by the common law of that country, is as incapable of inheriting as if his father and mother had never married; the second, by a species of legal Hibernicism, is denominated a *mulier*, or *mulier puisné*, and succeeds to the exclusion of the bastard eigné. Again, if there be an apparent impossibility of procreation on the part of the husband, as if he be only eight years old, or the like, then the issue of the wife is bastard. Likewise, in case of divorce in the spiritual court *a vinculo matrimonii*, all the issue born during the coverture is bastard; because such divorce is always upon some cause that rendered the marriage unlawful and null from the beginning. Bastard.

The duty of parents to their bastard children consists principally in maintaining them. For although bastards are not looked upon as children to any civil purpose, yet the ties of nature, of which maintenance is one, are not so easily dissolved; and these hold good even in other respects, as, for example, that a man shall not marry his bastard sister or daughter. The enactments relating to the maintenance and affiliation of bastards are numerous. The law is now regulated by the 7th and 8th Vict. cap. 101, as amended by the 8th and 9th Vict. cap. 10. The mother of a bastard is entitled to its custody in preference to the putative father, during the age of nurture; and by an earlier act (4th and 5th Will. cap. 76, § 71, amended by the 2d and 3d Vict. cap. 85) she was bound, so long as she remained unmarried or a widow, to maintain it as a part of her family until it attained the age of sixteen, or married, if a female; and by § 57 this liability attached, on the mother's marriage, to her husband, until her death or the child attained the age of sixteen. But under the 7th and 8th Vict. cap. 101, § 2, any single woman who may be with child, or who may be delivered of a bastard child, may either before, or within twelve months from, the birth of such child, or at any time thereafter, on proof of the payment of money by the alleged father for its maintenance within such period, obtain from a justice of the peace the issue of a summons to the petty sessions of such putative father. Thereupon the justices (or, in the metropolitan police district, a single magistrate, under the 8th and 9th Vict. cap. 10, § 9) may make an order for maintenance and costs, and enforce the same by distress and commitment. But it is necessary that the mother's evidence be corroborated in some material particular by other testimony to the satisfaction of the justices. The order by § 5 is determined upon the child attaining the age of thirteen years, or after the marriage of its mother, or after the death of the child; and the putative father is entitled under § 4 to appeal to the quarter sessions, upon entering into recognizances in the form provided by the 8th and 9th Vict. cap. 10, § 3. The 6th section declares the mother to be punishable for neglect or desertion of her bastard child as "an idle and disorderly person," and on a second conviction as "a rogue and vagabond," under the 5th Geo. IV. cap. 83 (amended by the 1st and 2d Vict. cap. 38), and any misapplication of moneys paid for the support of, or withholding proper nourishment from, or otherwise abusing and maltreating, such bastard child, is punishable under § 8 by a penalty of L.10.

The rights of a bastard are very few, being only such as he can acquire; for civilly he can *inherit* nothing, being looked upon as the son of nobody, and sometimes called *filius nullius*, sometimes *filius populi*. Yet he may gain a surname by reputation though he has none by inheritance, and may even be made legitimate and capable of inheriting by the transcendent power of an act of parliament. All other children have their primary settlement in their father's parish; but a bastard has his in the parish where he was born, unless such birth has been procured by fraud, or happened under an order of removal, in a state of vagrancy, in the house of correction, or under certificate; for in law he has no father. The incapacities attaching to a bastard consist principally in this, that he cannot be heir to any one; for being *nullius filius*, he is therefore of kin to nobody, and has no ancestor from whom an inheritable blood can be derived. Therefore, if there be no other claimant upon an inheritance than such illegitimate child, it escheats to the lord.

Bastard.

And as bastards cannot be heirs themselves, so neither can they have any heirs but those of their own bodies. For as all collateral kindred consists in being derived from the same common ancestor, and as a bastard has no legal ancestor, he can have no collateral kindred, and consequently no legal heirs, except such as claim by a lineal descent from himself. And hence, if a bastard purchase land, and die seised therefor without issue, and intestate, the land escheats to the lord of the fee. But under § 11 of the New Savings-Bank Act, 7th and 8th Vict. cap. 83, the trustees or managers are empowered to pay the money deposited by an illegitimate depositor to the persons who would have been entitled to the same, according to the statute of distributions, if he had been legitimate. Originally a bastard was deemed incapable of holy orders, and disqualified by the fact of his birth from holding any dignity in the church; but this doctrine is now obsolete, and in all other respects there is no distinction between a bastard and another man.

These are the principal incapacities attaching to bastardy in England. By the law of Scotland a bastard is not only excluded from his father's succession, because the law knows no father who is not marked out by marriage; and from all heritable succession, whether by the father or mother, because he cannot be pronounced lawful heir by the inquest in terms of the brief; but also from the movable succession of his mother, because he is not her lawful child, and legitimacy is implied in all succession deferred by the law. But a bastard, although he cannot succeed *jure sanguinis*, may succeed by destination, where he is specially called to the succession by entail or testament. In Scotland, as in England, a bastard can have no legal heirs except those of his own body; and hence, failing his lawful issue, the king succeeds to him as last heir. In Scotland bastards may be legitimated in two ways; either by the subsequent intermarriage of the mother of the child with the father, as already mentioned; or by letters of legitimation from the sovereign. With respect to the last, however, it is to be observed, that letters of legitimation, be their clauses ever so strong, cannot enable the bastard to succeed to his natural father; for the king cannot, by any prerogative, cut off the private right of third parties. But, by a special clause in the letters of legitimation, he may renounce his right to the bastard's succession, failing descendants, in favour of him who would have been the bastard's heir had he been born in lawful wedlock, such renunciation encroaching upon no right competent to any third party.

The number of illegitimate births (exclusive of still-born) registered during the year 1851 for England, appears from the fourteenth report of the Registrar-General, dated 24th June 1853, to have been 42,000 against 615,865 legitimate births, or a proportion of nearly 2 to 29. The following table, compiled (with the exception of the last item) from the Registrar-General's Sixth Report, and from Dr Stark's *Vital Statistics of Scotland*, exhibits the proportion of illegitimate births in various European states and one American.

States.	Year.	Total Births.	Illegitimate Births.	Ratio of Illegit. Births to 100 Births.	Proportion of Illegitimate Births.
Sardinia	1828 37	1,457,193	30,471	2·09	1 to 44·54
Sweden	1831 5	467,799	31,289	6·56	.. 15·23
Norway	1831-5	181,363	12,111	6·67	.. 14·97
England	1842	517,739	34,796	6·72	.. 14·88
Belgium	1842	138,135	9,354	6·77	.. 14·66
France	1842	982,896	69,928	7·11	.. 14·05
Prussia	1841	591,505	42,129	7·12	.. 14·03
Scotland (part of)	1835-45	4,305	328	7·61	.. 13·12
Denmark	1835 9	64,376	6,020	9·35	.. 10·69

Saxony	1841	70,094	10,512	14·99	.. 6·66
Bavaria	1838-9	149,185	30,729	20·59	.. 4·85
Chili	1848	46,143	10,235	22·18	.. 4·50

Bastards || Bastia.

It is a remarkable fact, as connected with the proportion of illegitimate children in the large towns, that in all the large towns in England the proportion of children born out of wedlock is much below what it is in the country districts. On the continent of Europe, on the other hand, the proportion of illegitimate births in the large towns greatly exceeds that of the country districts; and statists are pretty generally agreed that the existence of foundling hospitals in these towns has much to do with this result, encouraging and fostering bastardy as they do. The following table, compiled from the Registrar-General's Sixth Annual Report exhibits these facts.

Towns.		Total Births.	Illegitimate Births.	Proportion of Illegitimate per 100 Births.
Liverpool	English Towns.—The proportion of Illegitimate Births over all England in 1842 was 6·7 per cent.	9,923	274	3·0
London		60,240	1,925	3·2
Birmingham		5,094	207	4·1
Plymouth		1,199	50	4·2
Bristol		2,088	93	4·5
Sheffield		3,490	174	5·0
Leeds		6,376	349	5·5
Manchester		6,969	403	5·8
Bath		1,846	110	6·0
Salford		2,828	181	6·4
Newcastle-on-Tyne		2,449	156	6·4
Brighton		1,299	84	6·5
Wolverhampton		3,097	215	6·9
Genoa		33,034	2,665	8·0
Berlin		29,914	4,472	14·9
Frankfort		3,784	652	17·2
St Petersburg		9,625	1,809	18·8
Turin		36,313	6,867	18·9
Department of Seine (Paris)		40,005	11,527	28·8
Stockholm		13.291	5,409	40·7
Vienna		47,191	21,763	46·1

BASTARDS is also an appellation given to a kind of faction or troop of banditti, who rose in Guienne about the beginning of the fourteenth century, and joining with some English parties, ravaged the country, and set fire to the towns. They are supposed to have derived this name from having been headed by the illegitimate sons of noblemen, who were excluded from the rights of inheritance.

BASTARDY, ARMS OF, should be crossed with a bar, fillet, or traverse, from the right to the left. See HERALDRY.

BASTARNÆ, an ancient people in European Sarmatia, who, according to some authors, had emigrated from Germania. They were a powerful nation, occupying the country between the rivers Tyras and Borysthenes, about the mouth of the Danube, and seem to have belonged to the great race of the Celts.

BASTARNICÆ ALPES, in *Ancient Geography*, called also the *Carpates*, now the Carpathian Mountains.

BASTERNA, in *Antiquity*, a kind of litter or sedan-chair, in which the Roman ladies were carried by two mules. It was very similar to the *lectica*, which was borne by slaves. See LECTICA.

BASTIA, a fortified town and seaport on the eastern coast of the island of Corsica, and capital of an arrondissement of the same name. It occupies a very picturesque situation, rising from the sea in the form of an amphitheatre; but the town itself is ill built, and the streets narrow and crooked. The harbour, which is defended by a citadel, is only fit for small craft, and its entrance is narrow and difficult. Bastia is the seat of a royal court for the island, and of tribunals of commerce and primary jurisdiction; and has a communal college, a model school, and a museum. Its principal manufactures are soap, leather, liqueurs, and wax; and it exports oil, wine, coral, &c. Lat. 42. 41. 36. N. Long. 9. 27. 22. E. Pop. (1851) 14,523. Bastia was at one time the capital of Corsica. It was taken

Bastiat || Bastille.

by the English in 1745, and again in 1794. The arrondissement of the same name contains 20 cantons and 94 communes. Pop. in 1851, 70,288.

BASTIAT, FRÉDÉRIC, a celebrated French economist, born at Bayonne on the 29th June 1801. He studied in the colleges of Saint Sever and Sorèze, and then entered the commercial house of his uncle at Bayonne. He was made a justice of the peace in 1831, and some time afterwards a member of the general council of Landes. In 1840 he visited Spain and Portugal, where he paid especial attention to the customs and institutions of those kingdoms. His first literary essay, entitled *De l'influence des tarifs Français et Anglais sur l'avenir des deux peuples*, appeared in the *Journal des Economistes* in 1844, and contains the germs of the economic theory of the author, who afterwards appears as the decided opponent of the system of protection. He visited England soon after; and on his return to Mugron, where he resided, he continued his exertions in favour of free trade; as afterwards at Paris also. After the revolution of 1848, he became a member of the legislative assembly; and he died on the 24th December 1850, during a tour in Italy. His writings are as follow:—*Sophismes économiques; Propriété et Loi; Protectionisme et Communisme; Capital et Rente; Paix et Liberté; Incompatibilités Parlementaires; L'Etat, maudit argent; Harmonies économiques.*

BASTILLE, or BASTILE (from the French *bastir, bâtir*, to build), denotes a small antique castle, fortified with turrets. Such was the famous Bastille of Paris, which seems to have been the last castle that retained the name. It was commenced in 1370, by order of Charles V., and finished in 1382, under the reign of his successor. This building was strongly fortified, with numerous massive towers, which were united by a wall eight feet in thickness. The whole was surrounded by a ditch twenty-five feet in depth; and at subsequent intervals other additions were made to the fortifications, so as to render it an almost impregnable fortress. When Charles VII. retook Paris from the English in 1436, all his opponents in the city took refuge in the Bastille, which they were prepared to defend with vigour, but the want of provisions obliged them to capitulate. In 1588 the Duke of Guise took possession of the Bastille, and gave the command of it to Bussy-Leclerc. Soon afterwards he shut up the whole parliament within its walls, for having refused their adherence to the League. When Henri IV. became master of Paris he committed the command of the Bastille to Sully, and there he deposited his treasures, which at the time of his death amounted to the enormous sum of 1,870,000 livres. On the 11th of January 1649, the Bastille was invested by the forces of the Fronde, and, after a short cannonade, capitulated on the 13th of that month. The garrison consisted of only twenty-two men. The Frondeurs concluded a peace with the court on the 11th of March; but it was stipulated by treaty that they should retain possession of the Bastille, which in fact was not restored to the king till the 21st of October 1651. In that year took place the famous fight of the Porte Ste Antoine, between Condé and Turenne, on which occasion the forces of Condé owed their safe retreat into Paris to the cannon of the Bastille.

The chief use of the Bastille, however, was for the custody of state prisoners, or, more properly speaking, for the clandestine atrocities of a corrupt and cold-blooded despotism. Nowhere else upon earth, even in the dungeons of the Inquisition, had human misery by human means been rendered so lasting, so complete, and in many cases so irremediable, as in the Bastille. Of this one striking instance related by M. Mercier may serve as an example.

Upon the accession of Louis XVI. to the throne, the ministers then in office, anxious to obtain popularity by an act of clemency and justice, began their administration by inspecting the registers of the Bastille, and setting many prisoners at liberty. Amongst these was an old man, who had been a prisoner for forty-seven years. The sudden change from the solitude of his cell to the light and bustle of the outer world was too great for him; and finding that of the friends of his youth none now survived, he begged to be restored to the dungeon which had become his only home. The offence which had been visited by so terrible a punishment consisted in some unguarded expressions respecting Louis XV. These had been reported, very probably exaggerated, by some informer or enemy; a lettre-de-cachet had been issued; and the offender seized, committed to the Bastille, and forgotten.

Bastinado || Bastion.

Among the more distinguished personages who were confined in this fortress during the reigns of Louis XIV., XV., and XVI., were the famous *Man of the Iron Mask*, the Marshal Richelieu, Le Maistre de Sacy, De Renneville, Voltaire, De Latude, Le Prévost de Beaumont, Labourdonnais, Lally, Cardinal Rohan, Linguet, and La Chalotais. But, besides the numerous illustrious prisoners who at various times occupied the Bastille,—of whom many were more or less guilty,—its dreadful dungeons became the tombs of thousands of obscurer victims, whose very names were made to perish out of record, having been designedly defaced in the registers of the governors, or committed to loose leaves, that no trace of their fate might survive to satisfy the anxiety of friends or the curiosity of posterity. Thus in the reign of Louis XIV. the Bastille was a receptacle for innumerable innocent victims of religious tyranny; and, under the more degrading sway of his successor, for the fathers and brothers of the unhappy inmates of the *Parc aux Cerfs*.

At the breaking out of the French revolution, the Bastille was attacked by the Parisians, and, after a vigorous resistance, taken and razed to the ground. This memorable event occurred on the 14th July 1789. At the time of its capture only seven prisoners were found in it. A very striking account of this siege will be found in Carlyle's *French Revolution*, vol. i.

The site of the Bastille is now marked by a lofty column of bronze, dedicated to the memory of the patriots of July 1789 and 1830. It is crowned by a gilded figure of Mercury, spreading its pinions in the act of flight.

See the *Histories* of the Bastille by Renneville (7 tom. 12mo, 1713–24); Fougeret (8vo, 1833); Dufey de l'Yonne (8vo, 1834); Arnould (7 tom. 8vo, 1843–44); and the *Memoirs* of Linguet (12mo, 1821, new ed.); Carra (3 tom. 8vo, 1787); Charpentier (3 tom. 8vo, 1789); and Latude (edited by Thierry, 3 tom. 18mo, 1791–92).

BASTINADO, or BASTINADE, the punishment of beating or drubbing a criminal with a stick. The word is formed from the French *baston*, a stick, staff, or cudgel. The bastinado was a punishment used among the ancient Greeks, Romans, and Jews, and still obtains among the Turks. The Romans called it *fustigatio, fustium, admonitio, fustibus cædi;* which differed from the *flagellatio* in being done with a stick instead of a rod or scourge. Fustigation was a lighter punishment, and inflicted on freemen; flagellation a severer, and reserved for slaves. This was also called *tympanum*, because the patient was beaten with sticks like a drum. The punishment of the bastinado is much in use in the East at this day; and it is chiefly administered on the soles of the feet, which are sometimes beaten almost to a jelly.

BASTION, in modern fortification, a huge mass of earth, usually faced with sods, sometimes with brick, and rarely with stone, standing out from a rampart of which it is a principal part. This is what, in the ancient fortification, was called a *bulwark*. *Solid bastions* are those which have the void space within them filled up entirely, and raised of an equal height with the rampart. *Hollow bastions* are those surrounded only with a rampart and parapet, having the space within unoccupied, where the ground is so low that no retrenchment can be made in the centre, in the event of

Baston || Batavia.

the rampart being taken. *Flat bastion* is a bastion built in the middle of the curtain, when it is too long to be defended by the bastions at its extremes. *Cut bastion* is that which, instead of a point, has a re-entering angle. *Composed bastion* is when two sides of the interior polygon are very unequal, which makes the gorges also unequal. *Deformed bastion* is when the irregularity of the lines and angles puts the bastion out of shape; as when it wants a demigorge, one side of the interior polygon being too short. *Demi-bastion* is composed of one face only, with but one flank, and a demigorge. *Double bastion* is that which is raised on the plane of another bastion. *Regular bastion* is that which has its true proportion of faces, flanks, and gorges. See FORTIFICATION.

BASTON, *Baton*, or *Batune*, a staff or cudgel, borne in English coats of arms, as a badge of illegitimacy. In architecture it denotes the round moulding at the base of a column, also called a *torus*.

BASTON, *Robert*, a Carmelite monk, afterwards prior of the convent of that order at Scarborough, and also poet-laureate and public orator at Oxford, flourished in the fourteenth century. Edward II., in his expedition into Scotland in 1304, took Robert Baston with him in order to celebrate the victories he was to gain over the Scots; but the poet having been taken prisoner, was obliged to change his note and sing "the Bruce of Bannockburn." He wrote several pieces in Latin, on the Wars of Scotland, the Luxury of Priests, Synodical Sermons, &c.; and also a volume of tragedies and comedies, in English. He died about the year 1310.

BASTWICK, Dr JOHN, born at Writtle, in Essex, in 1593, was a physician at Colchester, who applied himself to writing books against popery. About 1633 he printed in Holland a Latin treatise entitled *Elenchus Religionis Papisticæ*, with *Flagellum Pontificis et Episcoporum Latialium;* in which the English prelates thinking themselves also aimed at, he was fined L.1000 in the High Commission Court, excommunicated, prohibited from practising physic, while his books were ordered to be burnt, and the author himself consigned to prison. Instead of recanting, however, he wrote *Apologeticus ad Præsules Anglicanos*, and another book called *The Litany*, in which he exclaimed vehemently against the proceedings of that arbitrary court, and taxed the bishops with an inclination towards popery. Prynne and Burton coming under the lash of the Star-chamber court at the same time, they were all censured as scandalous and seditious persons, condemned to pay a fine of L.5000 each, to be set in the pillory, to lose their ears, and to undergo perpetual imprisonment in three remote parts of the kingdom. The parliament in 1640 reversed these proceedings, and ordered Bastwick a reparation of L.5000 out of the estates of the commissioners and lords who had persecuted him. The civil commotions which ensued prevented his receiving this *solatium* for his sufferings; but, in 1644, his wife had an allowance ordered for her own and her husband's maintenance. The place and time of his death are unknown.

BAT. See MAMMALIA, *Index.*

BAT, BATE, or BATZ, a small silver coin, mixed with a large quantity of copper, current in several parts of Germany and Switzerland.

BATÂVI or BATĀVI. See BATAVORUM INSULA.

BATAVIA, a large city and seaport on the north coast of the island of Java, and the capital of all the Dutch settlements in the East. It is situated on the river Jacatra, in a swampy plain, at the bottom of a very capacious bay, and long was noted for the insalubrity of its atmosphere. More recently, however, the late Baron Capellen, one of the most enlightened governors that the Dutch ever sent out, sensible of the superior advantages which Batavia possessed as a place of trade, exerted himself to have the causes of its unhealthiness removed. He accordingly widened several of the streets, filled up some of the canals, cleansed others, demolished useless fortifications, cut down trees, &c.; and by the introduction of a number of judicious regulations, Batavia has been rendered as healthy as any other town on the island. Batavia.

The bay is formed by an indentation in the northern shore of Java; and it is protected from the swell of the sea by fifteen or sixteen small islands, interspersed in every direction across its mouth. It is perfectly secure at all seasons, the water being seldom disturbed in any violent degree by the winds. The city is of an oblong form, and the streets are quite straight and regular, crossing each other at right angles. Each street is from 114 to 204 feet broad, and has a canal in the middle, cased with stone, with a low parapet on the two margins, and is planted with a row of evergreen trees, under the shade of which are erected little open pavilions of wood, surrounded with seats, on which the Dutch inhabitants, in the cool of the evening, take their favourite refreshment of smoking. Beyond the trees is a gravelled road from 30 to 60 feet wide, for the various kinds of traffic, and it is terminated on the opposite side by a row of evergreens. The river Jacatra, which rises in the Blue Mountains to the south, flows through the middle of the town, and encircles it by several branches and canals connected with the main stream. Numerous other streams, such as the Ankee and the Tangerang, &c., besides artificial canals, intersect the swampy plain of Batavia in all directions, and connect the town with the surrounding country.

According to Sir Stamford Raffles, in his account of Java, there are now scarcely any remains of the splendour and magnificence which formerly procured for this capital the proud title of the Queen of the East. The public buildings consist of a Lutheran and a Portuguese church, a Mahometan mosque, a Chinese temple, the stadthouse, where the supreme court of justice and magistracy still assemble, the infirmary, the chamber of orphans, and some other institutions. The great church of Batavia, which was finished in 1760, at an expense of L.80,000, was taken down in consequence of its foundation having given way. The market is convenient and extensive, and well supplied with provisions. The fortifications by which the city was formerly surrounded, consisting of a wall defended by bastions, were all pulled down before Batavia was captured by the British in 1811. General Daendels directed the demolition of the ramparts, with a view of improving the health of the city by a freer circulation of air; and with the materials he built the new cantonment of Weltevreeden, about three miles inland, in a higher and more healthy situation. The castle of Batavia, which is on the north side of the town, next to the bay, is very spacious, and contains numerous buildings and extensive warehouses; but its situation was so unhealthy, that the troops were withdrawn to another place, and it was converted into a depôt for naval and military stores and other articles. The town of Batavia has been deserted by almost all of the more wealthy inhabitants, who now have their residences in the environs, principally on two roads leading to Weltevreeden; the one east, the other west, through Molenvliet and Ryswick. These elegant roads, shaded with rows of trees, and having on each side sumptuous houses surrounded with fine gardens and plantations, form the fashionable resort at Batavia. Here are situated some of the public buildings of the town, namely, the grand assembly-room, used by government on great occasions; also a large building which contains the treasury and all the other public offices.

Batavia, being a great trading city, is resorted to by many different nations in the East; and its population consists of a mixture of all these, as well as of Europeans. The inhabitants may be divided into the following classes, namely,

Batavia. the Dutch residents, who form but a small class, and can hardly be termed European, so completely are they intermixed with Portuguese and Malay colonists; the different Indian nations, originally slaves; the Moors and Arabs, an active and intelligent race, principally engaged in navigation; the Javanese, who are cultivators; the natives of Bali, of Celebes, Borneo, Macassar, Amboyna, and Madura. The Malays are numerous; they are chiefly boatmen and navigators, and profess the Mahometan faith. The Chinese form the most numerous class in Batavia. They are here, as everywhere else, ingenious, industrious, and mercantile in their habits. Many of them have acquired large capitals; and their industry embraces the whole system of commerce, from the greatest wholesale speculations to the most minute transactions in the retail trade. In their hands are all the manufactories, distilleries, potteries, &c.; they have large coffee and sugar plantations, and gardens well stocked with all sorts of vegetables; and they are the principal traders, smiths, carpenters, stone-masons, shoemakers, shopkeepers, butchers, &c., in the country. But though they form so useful a class in Batavia, they have always been severely oppressed by the tyrannical and arbitrary exactions of the Dutch government. All their religious festivals, every public ceremony and popular amusement, as well as every branch of industry, were subjected to taxation. They were obliged to pay for a license to wear their hair in a long plaited tail, according to the custom of their country, as well as for permission to bring their greens to market, and to sell their produce and manufactures in the streets. A better system was introduced under the British administration of Sir Stamford Raffles; but on the restoration of the island to the Dutch, they again had recourse to their former narrow and severe policy. The mean annual temperature at Batavia is 78°·3 Fahr., being in winter 78°·1, and in summer 78°·6; at mid-day it is from 80° to 90°, and at night 70°. There are several churches, the finest of which is the Protestant church in Koninghs Plaetse, several schools and hospitals, a theatre, museum, bank, and a society of arts and sciences. According to the census taken in 1842, the population consisted of 3025 Europeans and their descendants, 23,108 natives, 14,708 Chinese, 601 Arabs, and 12,419 slaves, making in all 53,861 persons, exclusive of the garrison; and may now (1853) be estimated at about 60,000.

Batavia is a great commercial depôt, and is resorted to by vessels from all the Asiatic islands, as well as from China, the East Indies, and Europe. Its trade was indeed heavily oppressed by the restrictions of the Dutch East India Company, who claimed the monopoly or pre-emption of almost all the staple articles of commerce; and who further restricted by their regulations the freedom of navigation. A greater latitude was allowed under the French regulations of General Daendels, though it was still sufficiently severe; and in 1811, when Batavia was captured by the British, the trade was set free from the shackles which had been imposed on it, and it accordingly began to flourish, and is now the principal trading port of those seas.

The exports from Batavia to the other islands of the archipelago, and to the ports in the Malayan peninsula, are rice, salt, oil, tobacco, teak timber and planks, Java cloths, brass ware, &c., and European, Indian, and Chinese goods. The produce of the Eastern islands is also collected at its ports for re-exportation to India, China, and Europe; namely, gold-dust, diamonds, camphor, benjamin, and other drugs; edible bird-nests, biche-de-mer, rattans, bees' wax, tortoise-shell, and dyeing woods from Borneo and Sumatra; tin from Banca; spices from the Moluccas; fine cloths from Celebes and Bali; and pepper from Borneo. From Bengal are imported opium, drugs, and cloths; from China, teas, raw silk, silk piece goods, varnished umbrellas, coarse China ware, nankeen, paper, and innumerable smaller articles for the Chinese settlers. Of late, however, the Chinese have been superseded by the introduction of British manufactures. A trade is also carried on with Japan, to which cloths, spices, elephants' teeth, wood, tin, tortoise-shell, &c., are sent; and the return is chiefly made in fine copper, China ware, lackered ware, and silk goods. Batavorum Insula || Batenites.

Batavia owes its origin to the Dutch general John Pieterson Coen, who, in 1619, took the town of Jacatra by assault, destroyed it, and founded in its stead the present city, which soon acquired a flourishing trade, and increased in extent and importance. The Dutch enjoyed unmolested possession of this place until the year 1811, when the states of Holland having been incorporated with France, a British armament was sent against the Dutch settlements in Java, and to this force the city of Batavia surrendered on the 8th of August. Batavia was restored to the Dutch by the treaty of 1814. Long. 106. 51. E. Lat. 6. 10. S.

See Stavorinus's *Voyages to the East Indies*; Barrow's *Voyage to Cochin China*; Sir George Staunton's *Embassy to China*; Thorn's *Memoir of the Conquest of Java*; Sir Stamford Raffle's *History of Java*; Temminck's *L'Inde Archipélagique*. (D. B—N.)

BATAVORUM INSULA, the island of the Batavi, was bounded, according to Tacitus, by the ocean, the Rhine, and the Vahalis, now the Waal. Cæsar extends it to the Mosa, or Meuse; but Pliny's description coincides with that of Tacitus. This island was, however, of greater extent in the time of Tacitus than in that of Cæsar; for, by a new canal, Drusus, the father of Germanicus, conveyed the waters of the Rhine into the ocean, a considerable way north of the former mouth of that river. The Batavi were a branch of the Catti, who, having been expelled their country in consequence of a domestic sedition, occupied the extremity of the coast of Gaul, at that time uninhabited, together with this island situated among shoals. The name of Batavi they carried with them from Germany. The modern name of this island is *Betu* or *Betaw*.

BATE, George, an eminent physician in the time of Charles I. and II. After having been principal physician to Charles I., he accommodated himself so well to the times, that he became afterwards principal physician to Oliver Cromwell. Upon the Restoration, he was again made principal physician to the king, and fellow of the Royal Society. He wrote in Latin an account of the civil commotions in England, and some other pieces.

Another George Bate wrote a work entitled *The Lives, Actions, and Execution, of the prime Actors and principal Contrivers of that horrid Murther of our late pious and sacred King Charles I.*

Bate Isle, an island of Hindustan, belonging to the province of Guzerat, situated at the south-western extremity of the Gulf of Cutch. This island has a good harbour, well secured from the prevailing winds, but with a rocky anchorage. The island of Bate is a great resort of Hindu pilgrims; and the town contains a large number of houses chiefly inhabited by Brahmins. Bate Isle was formerly a rendezvous for pirates, who were the dread of all traders on the western coasts of India. The castle is a place of considerable strength. In 1803 a naval force, consisting of a British frigate and two Bombay cruisers, succeeded in destroying several of the pirate boats and vessels; but an attack upon the castle, though conducted under the fire of the ships, was repulsed with some loss. In 1807 a treaty was entered into with the chiefs of the island, by which it was agreed that a free and open commerce should be permitted to all British vessels. The chiefs at the same time consented to relinquish their piratical practices, and the British government stipulated to afford every just support and protection to the Hindu temple of the island. Distance from Baroda W. 265 miles. Lat. 22. 8. Long. 69. 10. (E. T.)

BATENITES, a sect of apostates from Mahometan-

Bates ‖ Bath.

ism, dispersed throughout the East, who professed the same abominable practices with the Ismaelians and Kirmatians. The word properly signifies *esoteric*. See ASSASSINS.

BATES, WILLIAM, D.D., an eminent Nonconformist divine, born in November 1625. He was admitted to Emanuel College, Cambridge, and thence removed to King's College in 1644. He was one of the commissioners at the conference in the Savoy, for reviewing the public liturgy, and was concerned in drawing up the exceptions against the Common Prayer; notwithstanding which, he was appointed chaplain to King Charles II. soon after the Restoration, and became minister of St Dunstan's in the West; but he was afterwards deprived of his benefice for nonconformity. Dr Bates bore a good and amiable character; and was honoured with the friendship of the Lord-keeper Bridgman, the Lord-chancellor Finch, the Earl of Nottingham, and Archbishop Tillotson. He published *Select Lives of Illustrious and Pious Persons*, in Latin; and after his death, all his works, except his *Select Lives*, were printed in one vol. fol.; again in 1723; and in 4 vols. 8vo, in 1815. He died in July 1699, in the seventy-fourth year of his age.

BATH, the chief town of Somersetshire, is, from the elegance of its buildings and the beauty of its situation, allowed to be one of the handsomest cities in Britain. It stands on both sides of the river Avon, inclosed by an amphitheatre of hills belonging to the great western oolitic range. The town is well laid out, rising in beautiful terraces and crescents from the river; and its sheltered position renders the temperature mild and agreeable. It contains many fine public walks, and the vicinity presents a great variety of beautiful landscapes. The houses are mostly built of white freestone quarried in the vicinity. The abbey church is a handsome cruciform edifice, with a quadrangular tower 162 feet high, rising from the point of intersection. It is 210 feet in length from E. to W., and 126 in breadth from N. to S. There are 25 other parish churches and Episcopal chapels in Bath, besides numerous chapels belonging to the Independents, Baptists, Wesleyans, Roman Catholics, &c. There is a free grammar school founded by Edward VI., and free and other schools for boys and girls. The Roman Catholics have a college here; and a Wesleyan college has lately been erected. The literary and scientific institution, founded in 1826, is a handsome building of the Doric order, with a laboratory, lecture-room, library, and a museum containing a very valuable collection of Roman remains found here. Among its public buildings are the guild-hall, with an elegant Grecian front, founded in 1766; the assembly-rooms, opened in 1771, the ball-room of which is 106 feet in length by 43 in breadth and 42½ in height; the prison; market-house; theatre, one of the best out of London; and the pump-room of the king's bath, 85 feet in length by 56 in breadth, and 34 high, containing a marble statue of the celebrated Beau Nash, to whom the city is indebted for much of its prosperity. Bath has five banks; a new savings-bank, built in 1842; a number of charitable institutions; a mechanics' institute; and a school of arts. The thermal springs, to which the city principally owes its importance, rise near the centre of the city. They were known to the Romans, who had a station here under the name of *Aquæ Calidæ*, or *Aquæ Sulis*, commonly *Aquæ Solis*; and very extensive remains of Roman baths have been discovered here. The springs supply five distinct establishments, viz., King's, Queen's, Hot, Cross, and Abbey baths. The temperature varies in the different springs from 90° to 117° Fahrenheit, and the specific gravity of the hot bath is 1·002. Mr R. Phillips obtained from a quart of this water about 30 grains of foreign matter, viz., carbonic acid, 2·4 inches; sulphate of lime, 18·0 grains; chloride of soda, 6·6; sulphate of soda, 3·0; carbonate of lime, 1·6; silica, 0·4; oxide of iron, a trace; but much carbonic acid escapes from the springs. When fresh drawn, it has a slight chalybeate taste; and, taken internally, it acts as a stimulant. It is very beneficial in cases of palsy, rheumatism, gout, leprosy, cutaneous and scrofulous diseases. During the season, the city receives sometimes as many as 14,000 visitors. The Sydney Gardens have been open since 1795, and are frequently employed for horticultural exhibitions and other amusements. Negotiations are now in progress for the purchase of these grounds for the erection of a handsome proprietary college. The Victoria Park was opened in 1830. Bath now carries on no extensive manufactures, the fabrication of the coarse woollens known as "Bath coating" having much declined.

Knights of the Bath.

The earliest extant charter of the city is that granted by Richard I., which was afterwards confirmed by Henry III and extended to its present state by George III. The corporation consists of a mayor, 14 aldermen, and 42 councillors, and the town returns two members to parliament.

The Great Western Railway connects Bath with London and Bristol; from the former of which it is 107 miles distant, and from the latter 12 miles. The Kennet and Avon canal, which joins the Thames at Reading, connects Bath with London by water. The river Avon is here crossed by two stone, two iron, and three suspension bridges. Lat. 51. 23. N. Long. 2. 22. W. By the census of 1851, it contained 7744 inhabited houses, and 54,240 inhabitants.

BATH, a seaport town, county of Lincoln, state of Maine, North America, one of the principal commercial towns in the state, being advantageously situated on the western bank of the river Kennebec, 12 miles from its mouth. Ship-building is extensively carried on here. Pop. (1850) 8002. There are several other places of this name in the United States.

Knights of the BATH, a military order in England, concerning the origin of which antiquaries differ in their accounts. The earliest intimation we have of the order is in the reign of Henry IV., when we find a degree of knighthood under the express denomination of *the Bath*. On the day of his coronation in the tower of London, that king conferred the insignia of the order upon forty-six esquires, who had watched all the night before, and had bathed themselves. Thenceforth it was customary for our kings to confer this dignity on the occasion of their own coronations or those of their queens; on the birth or marriage of royal issue, and their first advancement to honours; upon the eve of intended expeditions against foreign enemies; at the installations of knights of the Garter; and when some grand anniversary festivals were celebrated. The last knights of the Bath so made were in 1661, at the coronation of Charles II.; after which the order was neglected until the year 1725, when George I. was pleased to revive it, and to command a book of statutes to be framed for the government of the order. By this code the number of knights was fixed at thirty-eight, namely, the sovereign and thirty-seven knights-companions. But, in the reign of George IV., the statutes of the order were relaxed; and, under the denominations of companions and grand crosses, a great additional number of persons, chiefly military men who had distinguished themselves in actual service, have been admitted.

The apparel of a knight of the Bath is a red surcoat, lined and edged with white, and girt with a white girdle, but without any ornament; the mantle, of the same colour and lining, is fastened about the neck with a lace of white silk, to which is attached a pair of white gloves, with tassels of silk and gold at the end; and on the left shoulder it is adorned with the ensign of the order, consisting of three imperial crowns *or*, surrounded with the ancient motto, *Tria juncta in uno*, wrought upon a circle *gules*, with a glory or rays issuing from the centre, and under it the lace of white silk worn by the knights of the Bath. Red breeches and stockings, and white hats surmounted with plumes of white feathers, complete the knightly apparel. The chapel of Henry VII. is the chapel of the order, and every knight's

Bath-Kol ‖ Bathing.

banner, with plates of his arms and style, is placed over his respective stall, in the same manner as those of the knights of the Garter in St George's chapel, Windsor; and the knights are allowed supporters to their arms.

Bath-Kol, "the daughter of the voice," a species of oracle, frequently mentioned in the Jewish books, especially the Talmud. (See Vitringa's *Observ. Sacr.* ii. pp. 341–363.) This was a fantastic method of divination invented by the Jews, though called by them a revelation of God's will made to his chosen people after all verbal prophecies had ceased in Israel. It was, in fact, analogous to the *Sortes Virgilianæ* among the Romans. For as, with the latter, the first words they happened to turn to in the works of the Mantuan bard were considered a kind of oracle prognostic of future events, so with the Jews, when they appealed to Bath-kol, the first words they heard from any man's mouth were regarded as a voice from heaven, directing them in the matter they inquired about. Even the Christians were not quite free from this superstition, often making the same use of the Scriptures as the Romans did of the works of Virgil; and it descended, through them, to later times. In France it was the practice for several ages to use this kind of divination at the consecration of a bishop, in order to discover his life, manners, and future behaviour; and the usage came into England with the Norman conquest; for we are told that at the consecration of William, the second Norman bishop of the diocese of Norwich, the words which first occurred on dipping into the Bible were, "Not this man, but Barabbas." William died soon after, and was succeeded by Herbert de Lozinga, chief simony broker to king William Rufus, on whose consecration the Bible opened at the words in which Jesus accosted Judas Iscariot: "Friend, wherefore art thou come?" This circumstance so affected Herbert that it brought him to a thorough repentance of his crime, in expiation of which he built the cathedral church of Norwich, the first stone of which he laid in the year 1096.

BATHGATE, a town and parish of Scotland, county of Linlithgow, on the great road between Edinburgh and Glasgow. Population in 1851, 3341, chiefly employed in weaving, and in working the limestone, coal, and ironstone in the neighbourhood.

BATHING, the act of using or applying a bath; that is, of immersing the body, or part of it, in water or other fluid.

Bathing is a practice of great antiquity. It prevailed among the Greeks as early as the heroic age; and we even find mention made by Homer of hot baths in the Trojan times, although these seem to have been rare; indeed Athenæus speaks of hot baths as unusual even in his age. Public baths were in fact discouraged, and even prohibited, by the ancient Greeks, who were content to perform their ablutions in private, and without either luxury or parade. The method of lavation among this people consisted in heating water in a large three-footed vessel, and thence pouring it on the head and shoulders of the bather while seated in a tub, and he, on coming out, was anointed with oil.

It was also long before the Romans came into the use of baths; the very name of which, *thermæ*, shows that the practice had been borrowed from the Greeks. As the ancient Romans were chiefly employed in agriculture, their custom was, every evening after work, to wash their arms and legs, that they might sit down to supper with more decency; for it is to be observed that the use of linen was then unknown, and the people of that age went with their arms and legs bare, and consequently exposed to dust and filth. But this was not all. Every ninth day, when they repaired to the city, either to the nundinæ or to attend at the assemblies of the people, they bathed in the Tiber, or some other river which happened to be nearest them. This seems to have been all the bathing known till the time of Pompey, when the custom of bathing every day appears to have been introduced. Bathing.

The Celtic nations were not unacquainted with bathing, although it must be confessed that some of their descendants have evinced but little taste for scrupulous ablution. The ancient Germans bathed every day in warm water during winter, and in cold water during summer. In England, the famous bath in Somersetshire is said by some to have been in use eight centuries before Christ. Of this, however, it must be owned, we have but slender evidence; although Dr Musgrave makes it probable that it was a place of considerable resort in Geta's time, the remains of a statue erected to that general, in gratitude for some benefactions he had conferred upon it, being still in existence.

Although bathing, among the ancients, made, as it were, a part of diet, and was used as familiarly as eating or sleep; yet, as we learn from Strabo, Pliny, Hippocrates, and Oribasius, it was in high esteem among their physicians as a cure for certain diseases; and hence their frequent exhortations to washing in the sea and plunging into cold water. The first instance of cold bathing for medicinal purposes is that of Melampus, who bathed the daughters of the king of Argos; and the first instance of warm bathing is that of Medea, who was said to boil people alive, probably with some reason, since Pelias king of Thessaly died in a hot bath under her hands. The cold bath was used with success by Antonius Musa, physician to the emperor Augustus, for the recovery of that prince; but it fell into neglect after the death of Marcellus, who was believed to have met his death from indulging in it to excess. Towards the close of the reign of Nero, however, it was again brought into vogue by a physician of Marseilles named Charmis; but the fashion proved short-lived, and, during the succeeding ages, when the physical condition of the people became as much deteriorated as their intellectual and moral character, this cleanly practice was altogether abandoned.

Medical and physiological effects of bathing.

A methodical arrangement of the medical and physiological effects of the practice of bathing, referred to the respective divisions of therapeutic agencies, would be of great use in enabling us to attain a distinct idea of their nature; but such an arrangement is, in fact, a matter of extreme difficulty, for two reasons: *first*, because the temperature, the continuance, and the impregnation of the bath, are capable of being so varied, as materially to vary the nature of the remedy without any distinct limit between its different forms; and, *secondly*, because the classes of medical agents to which several of these effects belong are by no means distinctly defined, to say nothing of the additional complexity arising from the division of the effects into immediate and remote, which is often extremely important. The remote effects, however, being of a more general nature, and relating chiefly to the improvement or deterioration of the actions of the whole system, it is only the immediate effects that require to be accurately analyzed and distinguished, and these we must endeavour to reduce to some methodical classification of therapeutic powers.

Baths, as depending on water, have been naturally referred to the class of *diluent* remedies, in which water is comprehended; and they have sometimes even been recommended as *nutrients:* they may also act as *excitants* of cutaneous sensation; as stimulants, or rather *calefacients*, increasing the velocity of the circulation of the blood; as *sudorifics*, as *diuretics*, as "sorbentia" or *sorbefacients*, as refrigerants or *astringents*, as *tonics*, and as *retardants* of the pulse, a capacity in which some would call them re-

Bathing. laxants, while they seem in many cases to be useful as antispasmodics, or to relieve certain nervous affections, by something like a *narcotic* or *sedative* power. We might also refer the mechanical effect of ablution, in removing the natural secretions of the skin, to the dietetic *habits* conducive to the preservation of health; but this process, though highly necessary for our comfort, is perhaps less essentially important to health than has often been imagined; and, in some particular cases, the practice of the very frequent removal of the unctuous and volatile secretions of the skin has even appeared to be injurious, and to occasion indolent tumours of the absorbent glands belonging to the parts concerned.

If we admit that baths are ever, strictly speaking, either *diluent* or *nutrient*, we must suppose the cutaneous absorbents to be the channels of these actions; and the majority of authors, both ancient and modern, have certainly considered the skin as imbibing, with great facility, not only water, but also any kind of substance capable of being dissolved in it; nor is there any doubt that, under some circumstances, the cutaneous absorbents have been found to possess such a power in a certain degree; but M. Séguin and Dr Currie have shown that, in common cases, very little or no effect is to be expected from this absorption;[1] that the strongest medical agents, when dissolved in the water of a bath, exhibited no operation on the system while the skin was entire; and that no perceptible advantage was obtained from a continued immersion in a bath of nutritive fluids, notwithstanding the extreme exhaustion of the system in a case of completely obstructed deglutition; and they suppose that where weight has been gained during immersion in a bath, the absorption occasioning its increase has been principally performed by the lungs retaining the moisture, which they receive in abundance with the air inhaled.

The other immediate effects of bathing must depend on the contact of the fluid with the skin, either as simply moistening and softening the cuticle, or as *exciting* a peculiar sensation in the cutaneous nerves, whether of touch only, or of heat or cold, or, in some cases, of slight pain, where the skin has been previously in a state of irritation, especially if the water contains a saline impregnation; or, *lastly*, as altering the state of the circulation by any of these means, especially by the change of temperature; this effect being also often modified by the change of the position of the body, and by the distribution of the pressure or resistance which supports its weight throughout almost the whole surface, instead of its being confined, as usual, to the parts on which we sit or stand. The excitement of the nerves of the skin appears to be salutary in many cutaneous diseases, which are benefited by warm bathing, whether in fresh or in salt water, or in sulphureous or other mineral waters, as at Harrowgate, and at Baden, and Pfeffer and Leuck in Switzerland, the bathers sometimes remaining whole days in the water for weeks together, until a peculiar efflorescence has appeared on the skin, and has again disappeared.[2] The mud baths in the north of Italy are of a nature somewhat similar, and are said to be of considerable advantage in some paralytic cases. But if we allow the truth of the opinion of Séguin and Currie, we must infer that there are few instances in which the effects of bathing on the system in general can depend much on the impregnation of the water; and we ought perhaps to attribute the acknowledged advantage of sea-bathing, in a variety of diseases, in a great measure to the mildness and equability of the temperature of the sea. It is true, that persons accidentally wetted with salt water are but little liable to take cold; and this fact has been supposed to indicate some stimulant property in the contents of the fluid; but it may be explained with greater simplicity from the slower evaporation of salt water, which causes it to carry off heat much less rapidly than fresh, the cooling process being also retarded by the greater moisture of the sea air. Bathing.

In order to determine how far any kind of bathing may properly be called a stimulant or *calefacient*, we must consider what are the tests by which we judge of the increased rapidity of the circulation of the blood. The term calefacient is, indeed, somewhat objectionable, as implying that animal heat depends solely or principally on the motion of the blood, which is not, in the present state of our knowledge, the most probable opinion; and besides this etymological inaccuracy, the definition of the term, as implying an accelerated circulation, involves a considerable difficulty, since we have no means of ascertaining whether increased frequency of pulsation compensates or not, in any particular instance, for diminished fulness and strength. On the other hand, the operation of almost all medical agents is such as to relieve us from this ambiguity in the application of the definition; for we can scarcely mention any remedy which materially accelerates the pulse without at the same time increasing its strength. There are, indeed, many medicines which are often designated by the vague denomination of stimulants, and which have no effect whatever on the circulation, but either simply *awaken* the nervous energies in general, or *excite* local sensations of heat or pain; and this multiplicity of significations is a sufficient reason for rejecting the term from a correct classification. It happens, however, not unfrequently, that astringent and febrifuge medicines will reduce the frequency of the pulse, and increase its fulness; and it becomes necessary, for an accurate analysis of the operation of remedies which affect the circulation, to distinguish the *accelerants* of the pulse from the *augmentatives* and the *intensitives*, all of which may possibly be independent of the production of an increase of temperature; and this increase may also in some cases be produced, at least in the extremities and the superficial parts, and apparently also in the whole system, without any change in the circulation, by the operation of certain remedies, which might be called *thalptics*, if it were necessary to distinguish them as independent agents: and to these four classes we might add four others of an exactly opposite nature, which might be called *retardants*, *diminutives*, and *remissives* of the pulse, and *psyctics*, or direct refrigerants; and the last four classes would belong to a general division of remedies comprehending those which lessen the force of animal actions; a division which it has not commonly been found necessary to establish, for any practical classification of the materia medica.

Now it appears that a hot bath, of a temperature exceeding 98°, the usual heat of the human body, will commonly act both as an accelerant and an augmentative of the pulse, but probably not as an intensitive; it may, however, very properly be classed as a calefacient, if such a description of remedies be admitted. Dr Parr[3] says, that a bath of 100° rendered the pulse fuller and more frequent; but that, after the bath, it was slower than usual; at higher temperatures the effects were still more marked; and in Marcard's experiments, p. 71, the results were nearly similar. Dr Haygarth observed (Marcard, p. 67), that in a bath of 114° the pulse was considered more fre-

Bathing. quent, and the arteries were evidently dilated. In Finland, according to Martin (Marcard, p. 223), the vapour baths are usually heated to about 120°, and they often increase the frequency of the pulse from 70 in a minute to 110 or 120. Fourcroy mentions a bath of 66°, which must have been of the centigrade scale, making 151° of Fahrenheit, and not 181°, as Marcard supposes (p. 216), which was followed, an hour afterwards, by a fatal apoplexy. Whatever exaggeration there may be in this report, it may still serve to explain to us the excesses which were frequently committed in the use of baths by the Greeks and Romans, and the pernicious effects attributed to them by the ancient physicians. Hippocrates observes (*Aph.* v. 16), that the too frequent employment of hot bathing causes a softness and debility of the muscles, a want of firmness of the nerves, and a dulness of the faculties, with occasional hemorrhages and faintings, sometimes even terminating in death; and in the *Clouds* of Aristophanes we have a mock defence of warm bathing deduced from the usual dedication of hot springs to Hercules, which implies a perfect confidence in the opinion of the pernicious tendency of the practice, accompanied, or followed, as it frequently was, by other indulgencies, to which it has too often given occasion. This traditional condemnation of hot bathing has been erroneously transferred by some of the moderns to warm or tepid bathing; and since it has been asserted by authors of high celebrity that air above 60° will generally occasion a sensation of warmth, it seems to have been inferred that water above 60° must constitute a warm bath, and consequently produce enervating and debilitating effects. The fact is, however, that a bath below 100° is scarcely ever heating in any material degree; and even at 100°, the pulse, though somewhat accelerated, is often not at all augmented in fulness; nor are the subsequent effects materially different from those which usually result from an equal acceleration produced by any kind of moderate exercise. It is observed by Galen, in his *Treatise on the Pulse* (*Opp.* vol. iii. p. 3, ed. Bas.), that "baths, when moderately warm, cause the pulse to be full, and strong, and frequent; when excessively hot, small and obscure, but frequent and hard, sometimes, however, after a time, becoming slow, though still feeble." Of this retardation of the pulse in a very hot bath we have no experience in modern times: it is obvious, that what Galen calls moderately warm, we should at present term a hot bath; and probably his excessively hot baths somewhat resembled that which is mentioned by Fourcroy. "Cold baths," he says, "at first make the pulse slow and weak; afterwards, if they disagree, and produce torpor, the pulse remains weak; but if the bath is likely to strengthen the system, producing a salutary glow, then the pulse becomes full and strong, and natural in point of frequency."

It is, however, remarkable, that the cold bath not uncommonly renders the pulse considerably more frequent at the first immersion; a circumstance which was particularly observed by Athill,[1] and which, notwithstanding Marcard's doubts, has been since fully confirmed by Dr Stock.[2] This increased frequency seems principally to depend on the painful sensation of cold occasioned by the first immersion, especially while it is incomplete; it is commonly very transitory, and is succeeded by a retardation, while the fulness of the pulsations is diminished from the first.

The *sudorific* effect of the hot bath seems to be, in a great measure, the natural consequence of the acceleration of the circulation, and to be nearly proportional to this acceleration, being also favoured by the softening of the cuticle, and perhaps by the dilatation of the cutaneous exhalants. It is principally recommended in rheumatism, and it is also considered as conducive to the cure of some cutaneous affections; and when this effect is thought particularly desirable, it is usual to take the bath late in the evening, and to promote its operation by going into a warm bed immediately after it. Bathing

In considering these and other changes produced in the system by bathing, we must be careful to avoid the very common error of applying inaccurately and indiscriminately the laws of mechanical and physical agents to the effects produced in the animal economy. Some of the latest and best authors on therapeutics have talked of the expansion of the fluids contained in the vessels, in consequence of the elevation of temperature occasioned by the warm bath, and of the contraction of the vessels themselves by the cold bath, as if they were phenomena of the same kind, and simply opposed to each other. The truth is, that the mean temperature of all the fluids in the body is seldom elevated more than a degree or two by the effect of a bath of any kind; and even if the elevation were 10°, the expansion of all the circulating fluids would not exceed the bulk of a single additional ounce of blood or of water. The mechanical effect of cold, on the other hand, would immediately tend to lessen the tension of the vessels, by contracting the fluid contained within them more than the vessels themselves; but this effect would be scarcely more sensible than the former, even if we allowed that the general temperature might be depressed 10° or 12°, as it seemed to be in some of Dr Currie's experiments; and the actual contraction, which is really observable in the superficial parts during immersion in the cold bath, can only be referable to the action of living powers, which fall decidedly under the description of involuntary muscularity Dr Parry's late experiments have very clearly shown the existence of such powers, and exhibited their temporary and local action.[3] He found, that when the carotid of a ewe was laid bare, its circumference was 525 thousandths of an inch; "but it almost immediately shrunk, through the whole space which was exposed, so as to become in circumference only ·470; at the same time, a portion of the artery, before the contracted part, and which had been more recently exposed, was ·635; the pulse in the dilated part was very strong and full, that in the contracted part very weak and soft." Dr Parry has chosen to distinguish these effects from those which are observed in other muscular parts by a peculiar denomination; but the distinction appears to be perfectly arbitrary; and Dr Young, whom he quotes as denying the muscular powers of the arteries, on account of the chemical nature of their coats, has expressly asserted their muscularity, in contradiction to the conclusions of Bichât and Berzelius. (*Medical Literature*, 8vo, Lond. 1813, p. 502.) But by whatever term we choose to denote the effect, there is little doubt that an unusual degree of cold has a tendency to produce such a general contraction of the coats of all the superficial capillary arteries; and the diminution of their diameter must necessarily increase that part of the resistance to the blood's motion, which is derived from its friction against the sides of the vessels, and must, therefore, tend materially to lessen its velocity. Again, if the contractions of the heart are at all proportional in magnitude or

Bathing. in frequency to the quantity of blood entering it, and acting as a stimulus to its motions, it is not unnatural to suppose that its pulsations will be rendered feebler by the diminution of that quantity, occasioned by the increase of the resistance, and that the primitive retardation will be redoubled by the operation of this cause. At the same time, however, that the cutaneous vessels are contracted, those of the internal parts must necessarily be enlarged. Hence arises the sensation of oppression on the chest, with the sobbing or panting for breath, which generally occurs at the first immersion in cold water, from the fulness of the vessels of the lungs, and which is increased, in some measure, when the immersion becomes total, by the pressure of the water on the abdomen, and consequently of the contents of the abdomen on the diaphragm. From the same cause arises also the pulsation in the descending aorta, which has been observed to be much more distinguishable after swimming than at other times (*Medical Transactions*, vol. v.); the internal vessels being distended so as to exhibit the effects of the heart's action more violently, and the heart itself beating with more than usual force in consequence of the exertion, while the contents of the abdomen are compressed, and are enabled, by the presence of the surrounding fluid, to transmit the pulsation very completely to the superficial parts, to which the hand is applied. The *diuretic* effect of a cold bath may be partly explained from a similar distension of the renal vessels, which must be favourable to the secretion of the kidneys; and if the same effect is sometimes produced in a hot bath, when the superficial vessels are rather dilated than contracted, it is in this case much less considerable than in the cold bath, and probably only takes place in consequence of the increased rapidity of the circulation, which affects the whole sanguiferous system.

The glow which succeeds to the first sensation of cold may be attributed in a great measure to the increased sensibility of the nerves after a partial torpor, rendering them more susceptible of the sensation of heat, which is always relative to the actual temperature of the skin; but it appears, from Dr Currie's experiments, that there is also sometimes a real increase of heat as measured by the thermometer; and it is probable that the causes concerned in the production of animal heat are called up into a more vigorous exertion, in a strong constitution, whenever they are required for the purposes of life; so that they first supply the superficial parts of the body, during the immersion, with as much heat as is necessary to overcome the painful sensation of cold, and afterwards, by a continuation of the same action, occasion an actual elevation of temperature above the natural standard. Dr Currie found, that, during the affusion of a bucket of cold salt water on the heads and whole bodies of two healthy persons, no depression of temperature was observable; but in a minute or two afterwards, although they remained without motion, the mercury rose 2°; in a third person of a feebler constitution, although the temperature remained equally unchanged during the affusion, it sunk, in a minute after, half a degree. These effects seem to be almost entirely independent of any change in the state of the circulation, which must be rather retarded than accelerated, while the generation of heat is increased. It is true, that the heart might be called into more powerful action at the same time that the pulsation at the wrist became feeble, from the permanent contraction of the radial artery; but the action of the heart would still be exhibited by the carotids, undisguised by this modification; and the carotids have not been observed to beat more strongly in the cold bath than at other times, although Dr Currie has remarked, that when "the pulse could hardly be felt at the wrist, the heart pulsated with great steadiness and due force;" a fact precisely analogous to Dr Parry's interesting experiment on the carotid of the ewe. Bathing.

Warm baths may be classed with propriety among the most useful *sorbefacient* remedies; but it is not easy to decide whether they are much more active in promoting absorption than other sudorifics, or than evacuants in general. When the weather deprives a valetudinarian of his accustomed walk, the bath often affords him a valuable substitute, increasing the appetite and promoting the digestion; but too great an appetite without muscular exercise is sometimes an evil, and this may have been one of the causes of the inconveniences occasioned by an abuse of bathing. A warm bath has often been of advantage in promoting the absorption of dropsical fluids, especially when they are of limited extent, as in cases of partial anasarcous swellings; but the most important sorbefacient effect of bathing is exhibited in the cure of glandular diseases, for which sea-water, whether in the form of a warm or a cold bath, has long been considered as a specific remedy; and there is no doubt that a residence by the sea-side, with a judicious employment of bathing, and the occasional internal use of sea-water, or of some equivalent remedy, has been of the most essential service to many constitutions which have exhibited these symptoms of general debility and languid absorption, the tonic and sorbefacient powers of the remedy being happily combined for invigorating and calling into activity the diminished energies of the constitution.

The refrigerant or *astringent* powers, both of warm and of cold bathing, have been abundantly elucidated by the late Dr Currie, who has introduced the remedy into general practice as a febrifuge, especially in the form of cold or tepid affusion, with the most salutary effects. It is not easy to determine how far the contraction of the superficial vessels by the astringent powers of cold, and how far the *retardation* of the pulse, which may possibly be dependent on that contraction, are concerned in the advantage derived from bathing in fevers; but it is at least obvious that the remedy does not operate simply by the abstraction of heat, since the tepid affusion is often more rapidly successful in abating fever than the cold. We may also collect from the experiments of Marcard, that a bath at about 90° is more efficacious in abating the frequency of the pulse, than at any lower or higher temperature; and these facts appear to afford a very strong argument against the hypothesis, that the principal utility of the cold affusion depends on the sudden shock which is given to the nervous system. Dr Currie has frequently found the pulse reduced by a single cold affusion from 120 or 130 to 80 or 90, and the heat from 104° or 106° to the natural standard. But he very properly limits the employment of the remedy to those cases in which the temperature is considerably elevated, and the arterial system is in strong action, without local inflammation; and where there is less vigour in the system, he often employs the tepid instead of the cold affusion, or even contents himself with moistening the face and the extremities; for instance, in hectic fever, the hands and feet only, which he finds actually hotter than the rest of the body. A late writer on consumption has very justly remarked how much of Dr Currie's reasoning on the effects of cold bathing had been anticipated by Galen, although, for want of a thermometer, he had not been able to employ the remedy in fever with safety. "Bathing," says Dr Young (*On Consumptive Diseases*, 8vo, Lond. 1815, p. 135), "is very strongly recommended in the Method of Healing, and the process is very minutely described: first warm air is employed, next warm water, and then cold water, and, lastly, the sweat is wiped off. When we are fatigued or dried up by exercise, the bath restores us to comfort, and defends us from fevers.

Bathing. A strong young man in the country will plunge into cold water at once when heated, and be much refreshed by it. Animals also wash themselves when they are hot, by a natural instinct, as they eat when they are hungry and seek warmth when they are cold. In fevers, if we had sufficient powers of discrimination, we might probably sometimes derive material advantage from the use of the cold bath, without premising the hot; and some persons have been actually benefited by this remedy. But without a more intimate knowledge of diseases than we possess, we cannot generally venture on the practice; and least of all in hectic fever, where there is not strength enough to bear the shock. A stout young man having a fever in warm weather, without visceral inflammation, would bring on a salutary perspiration by bathing in cold water; and if he were in the habit of cold bathing, he might have recourse to it with the more confidence; but for the hectic it is unsafe, especially when there is much emaciation: thus, in a hot and a dry summer, those who have travelled far, and are become thin and weak, have no need of being cooled, nor would it be safe for them to use the cold bath without first going into the warm. For we seem to be hardened by the cold bath like iron, when heated first; and if we previously warm ourselves by exercise, the effect is the same." Dr Currie's relation of an adventure of his own might almost be supposed to have been intended as a commentary on these remarks of Galen. (*Reports*, p. 120.) "On the 1st of September 1778, two students of medicine at Edinburgh set out on foot on a journey, a considerable part of which lay along one of the rivers of Scotland. They started by sun-rise, and proceeded with alacrity in the cool of the morning. At the end of eight miles they breakfasted, rested for an hour, and then resumed their journey. The day grew warm as it advanced, and after a march of eight miles more, they arrived heated, but not fatigued, on the banks of the river above-mentioned, about eleven in the forenoon. Urged by the fervour of the day, and tempted by the beauty of the stream, they stripped instantly, and threw themselves into the river. The utmost refreshment followed; and when they retired to the neighbouring inn, this was succeeded by a disposition to sleep, which they indulged. In the afternoon they proceeded, and travelling sixteen miles further at a single stretch, arrived at the inn where they were to sleep, a little after sunset. The afternoon had been warm, and they perspired profusely; but the evening was temperate, and rather cool. They had travelled for some miles slowly, and arrived at the end of their journey stiffened and wearied with their exercise. The refreshment which they had experienced in the morning from bathing induced, however, one of them to repeat the experiment, and he went perfectly cool into the same river, expecting to relax his limbs in the water, and afterwards to enjoy profound sleep. The consequences were very different. The Tweed, which was so refreshing in the morning, now felt extremely cold; and he left the water hastily. No genial glow succeeded, but a feverish chill remained for some time, with a small frequent pulse, and flying pains over the body. Warm liquids and frictions brought on at length considerable heat, and towards morning perspiration and sleep followed. Next day about noon they proceeded on foot, but the traveller who bathed was extremely feeble; and though they had to perform a journey of a single stage only, as some part of it was difficult and mountainous, he was obliged to take the assistance of a carriage which overtook them on the road. It was several days before he recovered his usual vigour."

The experiments of the same judicious author, published in the *Philosophical Transactions* for 1792, afford some striking illustrations of the effects of severe cold. He employed baths at the temperature of 44° and 40°; the natural pulse of the person subjected to the experiment was about 70 in a minute, and it was generally raised to 85 or more by the preparation for immersion; but in the water it invariably sunk to about 65, becoming firm, regular, and small. The change of temperature, as measured under the tongue, was still more remarkable, and greater than could have been expected either from reasoning or from former observations; for the mercury fell, within a minute or two after immersion, from 90° or 100° to 87° or 88°; it then rose gradually, but not regularly, in a quarter of an hour, to about 96°. Upon a second exposure to the wind, it fell to about 90°, and was in one instance lowered 2° more at the first immersion in a bath of 97½°, in which the natural temperature was by degrees recovered, although not much more rapidly than it had risen during the former immersion in the very cold water; but what raised it by far the most speedily was the application of very hot water to the region of the stomach. When, however, Dr Currie himself went slowly into a bath of 36°, in a light flannel dress, and remained in it for two minutes, no observable alteration was produced in the heat of his body; and this circumstance might almost induce us to suspect that the other subjects of his experiments had incautiously allowed their mouths to be cooled by the inhalation of the cold air. Dr Marcard's experiments (p. 71) not only confirm the fact of the general retardation and diminution of the pulse by the cold bath; but they show that the retardation commonly extends to all temperatures below that of the human body, becoming, indeed, much more remarkable in the tepid bath than in a bath of the ordinary temperature of the atmosphere, which does not appear to produce the effect with equal uniformity. Thus, in a bath at 60° and at 63° the pulse was rather accelerated than retarded. In six experiments from 70° to 80° inclusive, taking the mean of all the quantities in order to obtain a result less liable to accidental errors, and representing all the experiments in a compendious form, the temperature was 75°, and in 20 minutes the pulse was reduced from 78° to 70°; in four from 80° to 90°, the mean temperature was 87°, and the pulsations were reduced in 54 minutes from 91° to 75°; in three at 90°, the mean reduction in 36 minutes was from 97° to 75°; and three experiments above 90° give for a mean temperature 92°, and a reduction from 82° to 70°, effected in 35 minutes. Martean found a slight reduction of frequency at 93°; but at 96°, according to Dr Parr, there is commonly no observable change. (Marcard, p. 63, 66.)

From these experiments Dr Marcard very justly infers, that in a great variety of cases, the warm bath affords the only direct and certain mode of lowering the pulse without inconvenience (p. 88); and we must be contented with the empirical knowledge of this fact, without attempting to explain why a temperature of 90° is more favourable for the retardation of the pulse, than a much lower temperature, at which the thermometrical heat would certainly be more rapidly reduced. Dr Stock has also made several observations on the effect of cold bathing on the pulse; but, in his experiments, the retardation was much less constantly observable than the diminution; a variation which frequently occurs when the temperature is very low.

The salutary effects of cold applications, in some cases of gout, were well known to Hippocrates, and have been more lately extolled by Homberg, Floyer, and Pietschen. Marcard (p. 256) very properly states the objections to their employment; and, notwithstanding all that Dr Kinglake has done to recommend them, they have not been adopted by prudent practitioners, except in very recent

Bathing. cases, and in young and unbroken constitutions. Aretæus prescribes the affusion of cold water for giddiness and headache, and it has certainly been successful in some obstinate cases of this kind (Marcard, p. 255); and has even appeared to be a powerful palliative in some descriptions of mania. In fevers, Dr Currie found its effects more permanent than those of the tepid affusion, although not always so speedy.

We have ample experience of the *tonic* powers of bathing in more than one of its forms, although for a long period the great majority of practitioners in Great Britain were disposed to confine these powers within the limits of the cold, or at most of the tepid bath. But travellers in warmer countries had often informed us of the invigorating effect of a warm bath taken after fatigue; and Bruce, in particular, extolled its comforts and its salubrity, from having used it in Egypt. The opinions of Marcard on the same subject were partly made known through Beddoes. Count Rumford, in his thirteenth essay, has exhibited, in a popular point of view, the benefits which he himself derived from taking the warm bath habitually in the middle of the day rather than at night; and Dr Alexander Buchan, in his work on sea-bathing, has assisted in dissipating the remaining prejudices against its employment as a mild tonic. For feeble or enervated constitutions, and for persons who have suffered from great fatigue, it is decidedly preferable to the cold bath; but as the strength is gradually recovered, it may often increase its efficacy to lower the temperature by degrees. We may begin, for instance, with a warm bath at 96° or 98°, and lower it by degrees to 90° or a little less; and hence the transition to the open sea in the middle of a summer's day will not be too abrupt, the water being often heated to 70° or more on a coast well suited for bathing; and if the constitution appears to acquire strength under the experiment, the hour of bathing may be made earlier and earlier, until the temperature is no higher than about 60°. The time of remaining in the water may also be modified according to the powers of the constitution, a single immersion being the most easily supported, and a longer continuance in the water, till the sensation of cold has subsided, calling forth the faculty of generating heat into fuller action; observing always not only how the health appears to be affected, but which mode is the most conducive to the pleasure or comfort of the individual, which will often throw some light on the operation of the remedy. In most cases it will be found, that where either warm or cold bathing agrees with the constitution, it is followed by a sense of youth and vigour, and self-complacency, which is equally agreeable and salubrious. We must also make allowances for peculiarities of constitution, which may require a deviation from the temperature usually recommended. Thus there are some persons who have so singular a sensibility as to feel a bath of 110° not too warm, and to be absolutely chilled by a bath of 100°; and in such cases it is probable that at 105° the pulse would not be materially accelerated. In other instances the cold bath produces headache and dejection of spirits. This inconvenience is sometimes obviated by proper evacuations, which should also always be premised to bathing, where there is any appearance of visceral disease, or of congestion of any kind. The sea-water will answer this purpose sufficiently well, either alone or mixed with warm milk, or with some chamomile flowers infused in it; but it has no material advantage over any other cathartic which may be preferred by the patient. It is also recommended by all authors on cold bathing to plunge in head foremost, and this precaution is highly proper where there is any apprehension of headache; but in other cases it is of little moment. If, after all, the cold bath continues to disagree, it will be generally advisable to exchange it for the warm; and after a time it may be proper to give the cold a second trial. Bathing.

It is unnecessary to enter into a minute detail of the diseases in which bathing is useful as a tonic. It is, however, particularly indicated in a variety of complaints which are peculiar to females; and to weakly children, especially such as are ricketty and scrofulous, sea bathing is most essentially necessary. On the other hand, cold bathing is almost universally to be avoided where there is any consumptive disease, or any inflammatory affection of any of the internal parts; an exception which is easily understood, from the natural tendency of cold to cause a congestion of blood in the vessels of those parts, in consequence of the contraction of the superficial vessels. The sudorific effect of the warm bath, followed by the refrigerant quality of the tepid, and the tonic powers of the cold, exhibit a succession of remedies nearly analogous to the mode of treatment which is usually found to be most successful in fevers of various kinds; in most of which we begin with sudorific medicines, and proceed to astringents and tonics. Hippocrates, in his book on the use of liquids, observes that gout is one of the diseases in which both hot and cold applications afford effectual relief; and the remark is equally just with respect to some cases of rheumatism; but, more commonly, the best mode of using baths in rheumatism is to begin with a bath raised, during the immersion, to as high a temperature as the patient can bear, so as to act as a powerful sudorific, and to continue the course, when the pain has been relieved, at lower and lower temperatures, ending it with cold bathing in the open sea.

Notwithstanding the acknowledged utility of warm bathing in a variety of circumstances, there may possibly have been some exaggeration in the marvellous opinions which have been sometimes entertained of its utility for the prolongation of life. Galen has indeed mentioned a number of persons who had attained a great age, and who were in the habit of making daily use of the bath, which is enough to prove that such a habit cannot be extremely pernicious; and if we supposed a constitution to retain all its energies, but to have them concealed and obscured for want of proper stimuli, the warm bath might tend to remove the evil; but it is more natural to believe that the approach of old age has a tendency to weaken the radical powers of the constitution, which cannot afford to be roused into disproportionate exertion; and to apprehend that the temporary vivacity and activity superinduced by any foreign agent, whether by warm bathing or by a removal to a warmer climate, would only tend still more to exhaust the already diminished store of vitality.

The *narcotic* and *sedative*, or *specifically* antispasmodic, effects of bathing are most effectually exhibited, in ordinary cases, by the warm or tepid bath, which is often employed for the relief of pain, and for the removal of any irregular or convulsive affection. Possibly also the effect of the warm bath in retarding the pulse may be partly derived from its sedative power as affecting the heart; and if we take this connection for granted, we may infer from it, that the antispasmodic effect will be most advantageously obtained from a bath at 90°, which has been found to retard the pulse most effectually. But where there is internal inflammation, it may be desirable to dilate the superficial vessels by a bath somewhat hotter than this, so as to relieve the internal parts from a part of the fluid which distends them, but without increasing the velocity of the circulation by too high a temperature. The cold affusion is also a powerful remedy in many cases of tetanic disease. Hippocrates (*Aph.* v. 21) has remarked, that it often creates a glow which overpowers

Baths. the convulsive contraction, especially where the subject is young and athletic, the weather hot, and the disease independent of local injury; and the modern experience of Dr Wright and Dr Currie has confirmed and extended the observation. In another passage he tells us (*Aph.* v. 25), that the abundant affusion of cold water generally relieves and removes swellings and pains in the limbs, as well as spasms, producing a moderate degree of torpor, which supersedes the pain; but, in fact, the relief of inflammatory affections by cold is rather to be referred to its astringent than to its sedative powers. This is, indeed, a point which has been much discussed by modern theorists; but it must be confessed that all our theories are of little importance in physic, any further than as they assist us in clearly comprehending and distinctly remembering the facts which we derive from immediate experience in the treatment of diseases. (T. Y.)

BATHS, *Balneæ* (βαλανεῖα), large ornamented buildings erected by the ancients for the sake of bathing. Baths formed a part of the ancient *gymnasia*, though they were frequented more for the sake of pleasure than of health.

The most magnificent baths were those of Agrippa, Nero, Titus, Caracalla, Paulus Æmilius, and Diocletian. The baths of Agrippa, or *Thermæ Agrippinæ*, were built of brick, but painted in enamel. Those of Nero, *Thermæ Neronianæ*, were not only furnished with fresh water, but had the sea brought into them: those of Caracalla were adorned with 200 marble columns, and furnished with 1600 marble seats; and which, Lipsius assures us, were so large, that 1800 persons might conveniently bathe in them at the same time. But the baths of Diocletian, *Thermæ Diocletianæ*, surpassed all the rest in magnificence; 140,000 men having been employed many years in building them. A considerable portion of this vast structure, as well as of the baths of Caracalla, still remains; and, from the dimensions of the arches, the beauty of the pillars, the profusion of foreign marble, the curious moulding of the roofs, the multitude of spacious apartments, and a variety of other circumstances, these ruins may be regarded as among the most remarkable relics of ancient luxury and splendour. It is said that at Rome there were 856 public baths. Fabricius justly observes, that the excessive luxury of the Romans appeared in nothing more than in their baths. Seneca complains that the baths of plebeians were filled from silver pumps, and that the freedmen trod on gems; and Valerius Maximus and Pliny make mention of one Sergius Orata, who had baths suspended in the air. This, however, appears to have reference to the invention of the vapour bath, in which the flooring of the chamber was suspended over the hollow cells of the *hypocaustum*. (See Ausonius, *Mosella*.)

According to Dion Cassius (lv. 7), Mæcenas was the first who erected warm swimming baths at Rome; but there were public baths prior to his time, although they were small, poorly decorated, and of cold water only. Agrippa, while ædile, built 160 places for bathing, where the citizens might be accommodated either with hot or with cold water gratis; and, following his example, Nero, Vespasian, Titus, Domitian, Severus, Caracalla, Gordian, Aurelian, Maximian, Diocletian, and most of the emperors who studied to gain the affections of the people, erected baths inlaid with the richest marble, and wrought according to the rules of the most delicate architecture. The wealthy had baths, frequently of great magnificence, at their own residences, especially after the practice of pillaging the provinces had commenced; but these they only used on extraordinary occasions. The great men, and even the emperors themselves, sometimes bathed in public with the rest of the people. Alexander Severus was the first who allowed the baths to be opened in the night-time during the heats of summer.

The Greek baths were usually annexed to the *palæstræ* or *gymnasia*, of which they were considered a part; and consisted of seven different apartments, usually separated from one another, and intermixed with other buildings belonging to different sorts of exercises. These were, the cold bath, *frigida lavatio;* the *elæothesium*, or room where they were anointed with oil; the *frigidarium*, or cooling room; the *propnigeum*, or entrance of the *hypocaustum* or stove; the vaulted room for sweating in, or vapour bath, called *concamerata sudatio*, or *tepidarium;* the *laconicum*, or dry stove; and the hot bath, called *calida lavatio*. With respect to the baths disjoined from the palæstræ, they appear to have been usually double; one for men and another for women, but so near that the same furnace heated both. The middle part was occupied by a large basin, which received water by several pipes, and was surrounded by a balustrade, behind which there was an area for the reception of those who waited to use the bath. These baths were vaulted over, and only received light from the top.

In the Roman baths, the first part which appeared was a large basin, called κολυμβήθρα in Greek, and *natatio* or *piscina* in Latin. In the middle was the *hypocaustum*, which had a row of four apartments on each side, called *balnearia;* these were the stove, hot bath, cold bath, and *tepidarium*. The two stoves, called *laconicum* and *tepidarium*, were circular, and joined together; and their floor was hollow and suspended, in order to receive the heat of a large furnace, which communicated with the stoves through the vacuities of their floor. This furnace also heated another room called *vasarium*, in which were three large brazen vessels called *milliaria*, containing respectively hot, warm, and cold water, and so disposed that, by means of siphons and pipes, the water might be made to pass out of one or other of them into the bath, in order to adjust its temperature. Such is the description given by Vitruvius.

At three in the afternoon, which Pliny calls *hora octava et nona*, the Romans repaired to the baths, public or private. This was called the *hora balnei*, or the "bath hour." In summer the earliest hour of admission was eight, and in winter nine; whence the expression of Pliny applied to the hour of general resort. The public baths were opened at the sound of a bell, and always at the same hour. Those who came too late stood a chance of obtaining only cold water The bathers commenced with hot water; but when the pores had been thus opened, and a profuse perspiration produced, they thought it prudent to close them again, either with the cold bath, or at least with a sprinkling of cold water. During the bath the body was scraped with a kind of blunt knife or *strigil*, such as may still be found in the cabinets of the curious. Bathing was succeeded by unction and perfuming, after which they went fresh to the *cœnaculum*.

The Romans, when they found their stomachs overcharged, proceeded to the bath. This we learn from Juvenal, who inveighs against those who, having gorged themselves with eating, were forced to go into the baths to seek relief. They also repaired to a bath to refresh themselves after any considerable fatigue or travel; and hence Plautus says, on one occasion, that all the baths in this world were not sufficient to remove the weariness he felt. After Pompey's time the passion for bathing was carried to such excess that many were ruined, and some had brought themselves to such a state that they could not take food without first bathing. The Emperor Titus is said to have lost his life in consequence of the artificial habit thus induced. Hence Pliny inveighs against those physicians who held that hot baths aided digestion; and the Emperor Hadrian laid a restraint on the immoderate humour of bathing, by a public edict prohibiting all persons from bathing before the eighth hour.

BATHS, *Modern*. The modern baths consist of hot, warm, tepid, and cold baths, shower baths and vapour baths, in which the water and vapour used are either pure or variously medicated. With the exception of Russia and Turkey, baths are not used to any great extent among the inhabitants of

Baths. Europe. It is chiefly in warm countries that the bath is an indispensable luxury to the people, and in these countries the necessity of frequent ablutions and of attention to personal cleanliness is so recognized, that it has been embodied in the religious ceremonies of the Mahometans, Hindus, &c., and constitutes an essential part of their worship.

The Turkish and Persian baths, in their general construction, make a close approach to the ancient Roman baths. Lane, in his *Account of the Manners and Customs of the Modern Egyptians*, has given a full description of the Turkish baths as they exist at Grand Cairo. In that city there are between 60 and 70 public baths, some of which are kept exclusively for the men, others for the women, while others are used in the forenoon by the men, and in the afternoon by the women. "The building," says Lane, "consists of several apartments, all of which are paved with marble, chiefly white, with an intermixture, in some parts, of black marble, and small pieces of fine red tile. The inner apartments are covered with domes, which have a number of small round glazed apertures for the admission of light. The bather, on entering, if he has a watch and a purse containing more than a trifling sum of money, gives these in charge to the mallim or keeper of the bath, who locks them in a chest; his pipe and sword he commits to a servant of the bath, who takes off his shoes, and supplies him with a pair of wooden clogs, the pavement being wet. The first apartment is called the meslukh. It generally has two, three, or four leewans (raised part of the floor used as a couch), cased with marble, and a fountain of cold water, which rises from an octagonal basement, constructed of stone cased with marble, in the centre. One of the leewans, being designed for the accommodation of persons of the higher and middle orders, is furnished with mattresses and cushions; upon the other or others, which are for the lower orders, there is usually no furniture except mats. In many baths, there is also in the meslukh a small kind of stall for coffee.

"In warm weather the bathers mostly prefer to undress in the meslukh; in winter they undress in an inner closed apartment, called beytowwal, between which and the first apartment is a short passage with two or three latrinæ on one side. Beytowwal signifies 'first chamber;' and this name is given to the chamber here mentioned, because it is the first of the warm apartments; but it is less warm than the principal apartment, of which it is the ante-chamber. In general it has two mustubahs (raised seats). The bather receives a napkin in which to put his clothes, and another to put round his waist; this reaches to the knees or a little lower, and is termed makhzam; a third, if he requires it, is brought to him to wind round his head, in the manner of a turban, leaving the top of the head bare; a fourth to put over his chest, and a fifth to cover his back. When the bather has undressed, and attired himself in the manner above described, the lawingee (attendant) opens to him the door of the inner and principal apartment, which is called khararah. This, in general, has four leewans, like those of most rooms in private houses, which gives it the form of a cross, and in the centre a fountain of hot water rising from a small shallow basin in the middle of a high octagonal seat, cased with white and black marble, and pieces of red tile. The khararah, together with several chambers connected with it, may generally be described as occupying almost an exact square. The beytowwal is at one of the angles; two small chambers which adjoin each other, the one containing a tank of warm water, the other containing a trough, over which are two taps, one containing hot and the other cold water, termed the khanafeeyeh, occupy two other angles; while the fourth angle of the square is occupied by the chamber which contains the fire, over which is the boiler.

"The bather having entered the khararah, soon perspires profusely from the humid heat, which is produced by the hot water of the tanks and fountain, and by the boiler. The operator of the bath, called mookeyyisatee, immediately comes to him. The bather sits on one of the marble seats, or lies on a napkin on one of the leewans, or by the edge of one of the tanks, to submit to the first operation, which is that of cracking his joints. The operator cracks almost every joint of his frame: he wrings the body first one way and then the other, to make several of the vertebræ crack. Even the neck is made to crack twice by wrenching the head round, which produces a sensation rather alarming to an inexperienced person. Each ear is twisted round until it cracks; the limbs are twisted with apparent violence, but with such skill that an untoward accident is never heard of. The object of this process is to render the joints supple. The operator also kneads the bather's flesh. After this he rubs the soles of the feet with a kind of rasp of baked clay. There are two kinds of rasps used for the purpose, one very porous and rough, and its rasping surface scored with several lines, the other of a fine close clay; and those used by the ladies are usually encased in thin embossed silver. The next operation is rubbing the bather's flesh with a small coarse woollen bag, after which the bather dips himself in one of the tanks. He is next taken to a khanafeeyeh, and a napkin having been hung before its entrance, the operator lathers the bather with leef (fibres of the palm tree), and soap and sweet water. The soap is then washed off with water from the khanafeeyeh, when the bather, having finished washing, and covered himself with dry towels, returns to the beytowwal, and reclines on a mattress provided with cushions. Here he generally remains from half an hour to an hour or more, sipping coffee and smoking, while an attendant rubs the soles of the feet, and kneads the body and limbs; then dresses and goes out. One piastre is the common sum to pay for all the operations above described."

The Persian bath, and the processes followed there, as described by Sir R. Ker Porter, are almost entirely the same as those of the Turkish bath, so that it is unnecessary to enter into details on the subject.

The Russian bath is more properly a vapour bath, and is well described by Kohl in his *Russia*. His description is graphic and complete, though what he styles the "torture" of the process is considerably exaggerated. "On Saturday evening," he says, "an unusual movement may be seen among the lower classes in St Petersburg; whole companies of poor soldiers who have got a temporary furlough, troops of mechanics and labourers, whole families, men, women, and children, are eagerly traversing the streets with towels under their arms, and birch twigs in their hands. From the zeal and haste manifested in their movements, they would seem to be engaged on important business, as in fact they are, the most important and agreeable of the whole week. They are going to the public baths, to forget, in the enjoyment of its vapours, the sufferings of the past week, to make supple the limbs stiffened with past toil, and invigorate them for that which is to come. The Russians are such lovers of vapour baths, that Petersburg contains an immense number of these establishments. Before the door the words, 'Entrance to the Baths,' in large letters, invites the eye; within the doorway, so narrow that only one at a time can work his way in, sits the money-taker, who exchanges a ticket for the bath for a few copeks. Men, women, boys, and girls, all hurry to secure their tickets, as if proceeding to some favourite show.

"The passage is divided into two behind the check-taker's post, one for the male, and one for the female guests. We first enter an open space, in which a number of men are sitting in a state of nudity on benches, all dripping with water and perspiration, and as red as lobsters, breathing deep, sighing, puffing, and gossipping, and busily employed in drying themselves and dressing. These have already bathed, and now, in a glow of pleasurable excitement, are puffing and blowing like Tritons in the sea. Even in the winter, I have seen these people, all melting from the hot

Baths.

baths, drying and dressing in the open air, or, at most, in a sort of booth forming an outhouse to the bath. Round this space or apartment are the doors leading to the bathing-rooms, large wooden apartments, in which a heat of 40° or 50° Reaumur (122° to 145° F.) is maintained. Dr Robert Lyall mentions, that the heat is maintained by means of a large stove filled with stones, which are heated by means of burning wood, and over which water is thrown. The steam thence raised fills the apartment, which is surrounded with a wooden platform of ascending stairs or steps, and according to the degree of heat desired the person ascends the higher.

"The first sensations on entering this apartment are very singular, chiefly from the difficulty of breathing such a hot and moist atmosphere. On the platforms, which are raised in the form of an amphitheatre, lie an immense number of persons apparently inflicting torture on themselves; if not dead, they actually seem struggling with death, for the air they are breathing can only serve to stifle. Other persons, their tormentors, are employed in scourging them with birchen rods, steeped in cold water, as if to increase the smart. Others, standing by the glowing stoves, and steaming at every pore, have ice-cold water poured over them by pailfuls. When the first disagreeable effect of the heat is overcome, and the transpiration commences in full activity, then a beneficent spirit of warmth pervades the whole frame, and a divine sense of pleasure is all that remains to us of our existence, our whole being seeming dissolved in fleeting vapour. All pains and stiffnesses vanish from the limbs, and we feel light and buoyant as feathers. The rubbing and flogging with birchen twigs increases the transpiration, and consequently the enjoyment. All bodily pain, be it what it may, disappears in these baths; of headache, toothache, cramps, convulsions in the limbs or face, gout, or rheumatism, there remains not a trace. It is an extraordinary excitement, a kind of intoxication of the whole nervous system. By one of these baths a man is washed out like a sponge; for a sensual people I can imagine no higher enjoyment." (See also Acerbi's *Travels*.)

The baths in Germany, France, Italy, and Britain, are simply hot baths, in which the person, by himself, immerses the body for a longer or shorter time; and are chiefly used for purposes of personal cleanliness. The baths used by the modern Europeans and by the Americans, differ essentially from the Turkish and Russian baths, in that the vapour of water or steam is rarely made use of during the process of bathing; the operation being limited to washing or immersing the body in water of varied temperature, according as the person wishes a tepid or a hot bath. The form of the bath, therefore, differs essentially from those above described, consisting of a large or smaller building, containing a number of separate dressing-rooms, in each of which, or adjoining it, is an oblong trough of marble, slate, metal, or wood, furnished with two taps, one for the supply of the cold, the other for that of the hot water. The demand for these baths is very small over the greater portion of Europe, so that even large and populous towns cannot support above one or two bathing establishments of moderate dimensions.

One of the greatest improvements in modern times would be the general introduction of the Russian bath into the towns of Great Britain, &c. The vapour bath is infinitely superior to the warm bath for all the purposes for which a warm bath can be given; and as a medical agent in the removal and alleviation of certain chronic diseases can scarcely be over-praised. An effective vapour bath may be easily had in any house, and applied even to the greatest invalid at little cost or trouble. A pretty large firebrick is made red hot in the kitchen fire, and placed on an iron tray, which is raised on short feet. Over this is set a wooden chair, on which the person who is to take the vapour bath is seated; a four-leaved screen covered with painted canvass or cloth is then put round him, and a blanket or thick sheet thrown over the top of the screen, so as to convert it into a narrow closet or chamber. The person being provided with a small jug or watering-pan of hot water, pours the water very slowly over the red-hot brick, when, being converted into steam, it fills immediately the limited space, and almost instantaneously induces the most violent and general perspiration. We have for many years had experience of this mode of procuring an effective vapour bath, and can confidently recommend it. (J. S—K.)

Bathurst.

BATHURST, Allen, Earl of Bathurst, one of the last luminaries of Queen Anne's reign, was born in the year 1684. His studies and education were equally conducive to the brilliant figure he was destined to make in social life and in the senate, as a polite scholar, patriot, and statesman. These talents he had an opportunity of displaying as early as the year 1705, when, at the request of his father, Sir Benjamin Bathurst, and the solicitation of the constituency of Cirencester, he represented that borough in parliament. He distinguished himself particularly in the struggles and debates relative to the union between the two kingdoms; firmly supporting a measure which he thought calculated to strengthen the government and add to the prosperity of the country. Though he was contented to act a subordinate part in the opposition planned by Mr Harley and Mr St John, his intimate friends, in order to sap the credit of the Duke of Marlborough and his adherents, nevertheless he did good service to his party by arraigning, with more eloquence than truth, the conduct of the general and of the Earl of Godolphin, whom he accused of lavishing the treasures of the nation on conquests more splendid than serviceable. The loss of the battle of Almanza, which happened about this time, seconded his efforts and those of his associates in dispelling what they called the intoxication of former successes, and disparaging achievements which reflect immortal honour on the British name. But his personal regard for Lord Somers, president of the council, suffered no abatement, although they were of different opinions in politics; and when that great man was deprived of office, Mr Bathurst acted with such tenderness and delicacy as to preserve his esteem in a private station. In consideration of his zeal and services, the queen, in 1711, advanced him to the peerage by the title of Baron Bathurst, of Battlesden, in Bedfordshire.

His lordship continued to speak his sentiments with undaunted freedom in the upper house, and became a vigorous opponent of the court measures in the reign of George I., and during Sir Robert Walpole's administration. The acrimony of the prosecutions carried on against the Earl of Oxford, Lord Bolingbroke, and the Duke of Ormond, stimulated his indignation against such vindictive proceedings; and he observed, "that the king of a faction was but the sovereign of half his subjects."

The South Sea Scheme having infected all classes with a spirit of wild speculation, when the people awoke from their delirium a vast number of families were involved in ruin. Lord Bathurst publicly impeached the directors, whose arts had enabled them to amass enormous fortunes during the prevalence of the mania; he represented that the national honour was concerned in stripping them of their ill-gotten wealth; and he moved for having all the directors of the South Sea Company punished for their sordid knavery, by the forfeiture of their estates.

When the bill was brought into the House of Lords against that learned prelate Dr Atterbury, bishop of Rochester, his lordship spoke against it with great vehemence. He concurred with all his might in the opposition to Sir Robert Walpole; and when, after an obstinate struggle, this minister was forced to resign all his employments, Lord Bathurst was sworn of the privy council, and made captain of the gentlemen pensioners, a post which he resigned in 1744. In 1757 he was appointed treasurer to George III. (then

Bathurst || Bathycles.

Prince of Wales), and continued in the list of privy counsellors at that monarch's accession to the throne; but, on account of his advanced age, he declined embarking again in political contentions.

Lord Bathurst's integrity gained him the esteem even of his opponents, while his humanity and benevolence procured him the affection of all who knew him more intimately; and he added to his public virtues all the good breeding, politeness, and elegance, of social intercourse. Congreve, Vanbrugh, Swift, Prior, Rowe, Addison, Pope, Arbuthnot, Gay, and most of the men of genius of his own time, cultivated his friendship, and were proud of his correspondence. Pope, in his *Epistle on the Use of Riches*, which is addressed to Lord Bathurst, compliments his friend in some highly characteristic lines. Sterne, too, in his letters to Eliza, speaks of him in terms of affectionate admiration. "This nobleman," says he, "is a prodigy; for at eighty-five he has all the wit and promptness of a man of thirty; a disposition to be pleased, and a power to please others, beyond what I ever knew; added to which, a man of learning, courtesy, and feeling."

Lord Bathurst was elevated to an earldom in 1772, and lived to see his eldest son promoted to the peerage by the title of Baron Apsley, and several years lord high chancellor of Great Britain. His lordship married Catharine, daughter of Sir Peter Apsley, by whom he had two other sons and five daughters. He died, after a few days' illness, at his seat near Cirencester, on the 16th of September 1775, in the ninty-first year of his age.

BATHURST, *Ralph, M.D.*, uncle of the preceding, was born in the year 1620. He studied divinity in Trinity College, Oxford; but, on the breaking out of the civil war, he changed the course of his studies, and, applying himself to physic, took a doctor's degree in that faculty. By dint of assiduous application, he soon rose to eminence in his profession, and in the time of the Commonwealth was appointed physician to the state. At the Restoration, however, he quitted the practice of physic; was elected a fellow of the Royal Society, and president of his college; and, having entered into holy orders, was made chaplain to the king, and afterwards dean of Wells. Soon after, he filled the office of vice-chancellor of Oxford, and was nominated by King William and Queen Mary to the see of Bristol; but this honour he declined. To the accomplishments of an orator, philosopher, and poet, he added an inexhaustible fund of wit. Ridicule—of which he was an absolute master—was the weapon with which he used to correct the delinquents of his college. His poetical pieces in the *Musæ Anglicanæ* are excellent in their kind; besides which he wrote several poems, both in English and Latin. He died June 14. 1704, in his eighty-fourth year.

BATHURST, a county in the colony of New South Wales, lying between the rivers Lachlan and Macquarie. In the Bathurst mountains the first great gold digging began in May 1851. See AUSTRALIA. The town of Bathurst, 98 miles W.N.W. of Sydney, has since that time greatly increased in size and importance. Pop. of county in 1851, 6405.

This is also the name of a seaport town of Western Africa, capital of the British colony of Senegambia, at the mouth of the Gambia river, in N. Lat. 13. 28. W. Long. 16. 32.

BATHURST ISLAND, on the north coast of Australia. See AUSTRALIA.

Another island of the same name lies in the arctic seas, in Lat. 75. N. Long. 100. W. Parry traced, in 1819, its southern coast for 75 miles, and describes it as desolate, rugged, and precipitous.

BATHYANI. See HUNGARY.

BATHYCLES, of Magnesia in Lydia, the celebrated sculptor of the throne or shrine of the Amyclæan Apollo, so minutely described by Pausanias (*Laconia*). This eminent artist gave a stimulus to the genius of Grecian sculpture. He came into Greece about 600 years B.C., at the time when the invasion of the Scythians and of the kings of Lydia harassed the Ionian states, and fixed his abode at Sparta.

Bathyllus || Batnears.

BATHYLLUS of Alexandria, a freedman of Mæcenas, was a celebrated pantomimic dancer in the reign of Augustus. See BALLET.

BATILUS, a musical instrument of percussion, made of metal, in the form of a staff, furnished with metallic rings. It was used by the Armenians in their church-service.

BATISTE, in *Commerce*, a fine kind of cloth, of mixed silk and woollen, manufactured in Flanders and Picardy.

BATMAN, in *Commerce*, a kind of weight used at Smyrna and several other places, usually containing six okes of 400 drachms each.

BATMANSON, JOHN, prior of the Carthusian monastery, or Charter-house, London. He studied at Oxford, and wrote against Erasmus and Luther, at the instigation of Lee, archbishop of York. He died in 1531.

BATNÆ (Sarug), an ancient city of Osroëne in Mesopotamia, celebrated for its great fair, which was attended by merchants from Syria and India.

BATNEARS or BATTIES, a people of the northern part of Hindustan, inhabiting the tract of country now included within the British district of Bhutteeana, the eastern frontier of which is situated 125 miles N.W. of Delhi. The Batties present many peculiarities in manners and customs, distinguishing them from the other people of Hindustan. They consist of two distinct races; the one being composed of Mahometans of Rajpoot descent, who constitute the influential class, and who report among themselves that their ancestors emigrated some centuries ago from the district of Jessulmere, and, after various vicissitudes, settled in the Batnear country; the other comprising the common people known as Jauts, who have adopted the religion of their superiors, and are consequently treated with great moderation. Most of these people are descended from dwellers on the western bank of the Sutlej, who were invited by a rajah of the Batties to cross the river and settle in his country. Though tillers of the soil, the Batties are more generally characterized as shepherds; and although principally restricted to the territory whence their name is derived, various tribes of them are to be found in the Punjab, and they are also scattered over the high grounds to the east of the Indus.

Notwithstanding they are Mahometans, yet their customs are in some respects at variance with those observed by the majority of the followers of the prophet, particularly in the females appearing, without any reserve, unveiled in public, and in their associating promiscuously with the men. The wives of the Rajpoot chiefs form an exception.

The territory above described, anterior to British sway, was under the dominion of a supreme prince or rajah, whose authority was acknowledged by inferior chiefs. This potentate could bring 20,000 or 30,000 men into the field, but they were quite undisciplined, and despised the necessary principle of subordination. His revenue arose chiefly from the plunder of his troops; for their wars were directed more to predatory purposes than to open contest, and the rajah, instead of repressing the ravages of this immense banditti, willingly participated in the spoils.

While under the influence of native rule, the Batties appear to have formed a collection of hordes of freebooters. They have been described as of a cruel, savage, and ferocious disposition; entertaining an utter abhorrence of the usages of civilized life; being thieves from their earliest infancy, and during their predatory incursions into the neighbouring districts, not scrupling, though unresisted, to add murder to robbery.

Many of the Batties appear to be entirely nomadic; changing their residence from place to place as subsistence

Batnears. fails. Their exports are horses, camels, bullocks, buffaloes, and ghee; and occasionally they sell some surplus grain above what is necessary for their own consumption; but their traffic is very inconsiderable. A large portion of the country is unproductive, but along the banks of the river Cuggur, from Batnear to the town of Sirsuh, and also in the vicinity of the Nullah, called the Nyewal, the soil is uncommonly rich, and well adapted for cultivation. The inundations of these rivers fertilize their banks, and the subsidence of the waters leaves them to a great distance prepared for plentiful crops of wheat, rice, and barley, amply rewarding the labours of the husbandman.

We are unacquainted with any river of note in this district, excepting the Cuggur, and even this is lost in the sands to the westward. It is, however, in contemplation to construct a canal from Roopur on the Sutlej, communicating with the Cuggur near the town of Putteeala, whence a never-failing supply of water for purposes of irrigation would be available to a considerable portion of the Bhattee territory.

The former capital of the Batties was Batnear, which lies in a situation almost inaccessible to an enemy, for no water is to be procured within twelve miles but what supplies the inhabitants. It was taken, however, in 1398 by Timour, more recently by the military adventurer George Thomas, and finally in 1805, by the rajah of Beykaneer, who still retains authority over it. The principal town is Sirsuh, between which and Bahawulpore a route for commercial purposes has been opened. Numbers of the Batties have emigrated from their native country, to establish themselves in the western parts of the dominions of Oude; and several families of them are to be met with in Rohilcund. They are practised travellers, and well trained to emigration by the laborious journeys undertaken in crossing the great desert to the west of their territories. During the independence of their native rulers, expeditions were frequently made in large parties for the purpose of a predatory incursion on some peaceable country more remote; and these banditti exemplified both skill and determination in attaining their object. Camels previously laden with provisions were despatched to different stations in the desert, which is about 130 miles in breadth, and their loads deposited there. The most intelligent of the party about to follow were then selected as guides, and enforced the most implicit obedience from their companions during the journey, which closed at the frontier of the hostile country, or rather that against which their hostility was directed. The guides by long experience became expert without compass or landmark, and seldom failed to conduct the party to the appointed station where the provisions were deposited, and thence across the remainder of the desert in safety. If accidentally they missed the points of rendezvous, or those where alone their necessities could be relieved, they were exposed to inevitable destruction. The adventurers steered their course by the sun in the day-time, and by the polar star at night; and by similar aids they were enabled to retrace the way they had travelled.

The history of the Batties has attracted the notice of few European authors. They seem to have carried on frequent wars with neighbouring states, and were the most formidable enemies opposed to the rajah of Beykaneer. The latter, however, invaded their territories in the beginning of the present century, and obtained some temporary advantages. He erected a fortress in Batinda, now a possession of the rajah of Putteeala, and this contributed to overawe them for a time, and repressed their incursions into his own dominions; as, independently of the garrison, he stationed a large body of cavalry in the fort, whose frequent sallies and captures of cattle annoyed the Batties so much, that they contemplated a total emigration from their own country. But George Thomas, the military adventurer already noticed, an Irishman by birth, who, endowed with singular talents and intrepidity, had founded for himself an independent state in the north-west of India, was then at war with the province of Beykaneer. Having reached its frontiers, the Batties solicited his alliance, and, to induce him to espouse their cause the more readily, offered him 40,000 rupees if he would reduce the obnoxious fort. It appears that the Beykaneer forces were now masters of Batnear, the capital, whither General Thomas, who had accepted the proposals of the Batties, marched to dislodge them. He found a numerous garrison, and, having brought up his artillery, began to batter the place preparatory to an assault. This, however, the enemy avoided by capitulation, and they were allowed to evacuate the city with the honours of war, when the Batties immediately took possession of it. In further prosecution of the war, several actions ensued, and various fortresses were taken; but it would appear that one of the Battie chiefs, at variance with General Thomas, commenced hostilities against him about the period now alluded to; and in this new warfare with his late allies his forces were so much reduced by repeated encounters, that being scarcely able to stand an engagement he fortified his camps. The Batties, after frequent attacks, withdrew their troops by night; whereupon General Thomas took and burnt Futtehabad and other places, and might have occupied the whole country, had not a neighbouring chief concluded an alliance with the Batties, and sent 1000 cavalry to their aid. General Thomas retreated to Jyjur, a town within his own territory, leaving the Batties in possession of their capital, which, however, as already mentioned, was subsequently captured by the rajah of Beykaneer.

Baton Rouge || Batsch.

The triumphs of the British arms proved fatal to the European adventurers who at that period had established themselves in Northern India, and the arrangements made with Scindia brought the British into contact with the country of the Batties, against whom they were compelled in 1810 to march a force, which expelled the chief and transferred the greater part of the territory to his son, who had voluntarily proceeded to the British camp. The previous evils continued, however, in a great degree to prevail. In 1818 further steps became necessary, and up to a comparatively recent period much irregularity continued to prevail. The attention of the British government, however, has been seriously turned to its abatement. (E. T.)

BATON ROUGE, a town in the state of Louisiana, North America, situated on the left bank of the Mississippi, 120 miles above New Orleans. It has a court-house, jail, state penitentiary, college, &c., and in 1849 was made the capital of the state. Pop. (1850) 4200.

BATON, or *Batoon*. See BASTON.

BATONI, *Pompeo Girolamo*, a native of Lucca, who was considered in Italy as a great painter in the eighteenth century; but his altar-pieces in various parts of Italy, and his works in Lisbon, where some of his best are exhibited, show the decay of the Roman school in that century from the grandeur of the preceding epoch. He was born in 1708, and died at Rome in 1787. Lanzi, *Storia Pittorica;* Reynolds's *Lectures*.

BATRACHIANS. See REPTILES.

BATRACHOMYOMACHIA, or "battle of the frogs and the mice," the title of a mock heroic poem generally ascribed to Homer, though without any good foundation. The subject of the work is the death of Psycharpax a mouse, son of Toxartes, who having mounted on the back of Physignathus a frog, was being conveyed to her palace to which she had invited him; but being seized with fear at seeing himself in the middle of the pond, he tumbled off and was drowned. Physignathus being suspected of having intentionally shaken off Psycharpax, the mice demanded satisfaction, and unanimously declared war against the frogs.

BATSCH, AUGUSTUS JOHN GEORGE CHARLES, a dis-

tinguished naturalist born at Jena in 1761. He was the author of *Elenchus Fungorum*, and numerous other works, chiefly botanical, by which he acquired a high reputation. He died in 1802.

BATTA, a Hindustanee word applied to the allowance given to East Indian troops in the field. In garrison they are allowed *half batta*.

BATTALIA, an army ranged in order of battle, or ready for engagement.

BATTALION, the lowest integral denomination in an army or national military force. Hence two or more battalions constitute a regiment, two or more regiments a brigade, two or more brigades a division, two or more divisions a corps d'armée, and two or more corps d'armée a grand army. A battalion is the unit or integer in all the combinations of an armed force. A battalion usually contains from 500 to 800 men; but the number is not determined. They are divided into eight or more companies, one of which is grenadiers. Some regiments consist of but one battalion, others are divided into four or five. See ARMY.

BATTAS, a fertile and populous country in the island of Sumatra. See SUMATRA.

BATTEL, or *Trial by the Wager of Battle*, in English law, a species of trial of great antiquity, but now abrogated by positive statute. See APPEAL. It seems to have owed its origin to the military genius of our ancestors, joined to a superstitious belief that Heaven would interpose, and give the victory to him who had the right. The decision of suits, by an appeal to the God of battles, is believed by some to have been invented by the Burgundians, one of the northern or German clans who established themselves in Gaul; and it is certain that the earliest written injunction of judiciary combats to be found is in the laws of Gundebal, which are preserved in the Burgundian code. Yet it does not seem to have been merely a local custom peculiar to particular tribes, but the common usage of all those warlike nations from the earliest times. From a passage in Velleius Paterculus, it appears that the Germans, when they first became known to the Romans, were accustomed to decide all contests of right by the sword; for when Quintilius Varus endeavoured to introduce among them the Roman laws and method of trial, it was looked upon, says the historian, as a *novitas incognitæ disciplinæ, ut solita armis decerni jure terminarentur:* and among the ancient Goths in Sweden we find the practice of judicial duels established upon much the same footing as they formerly were in our own country.

This species of trial was introduced into England, along with other Norman customs, by William the Conqueror; but it was only used in three cases; first, in the court martial, or court of chivalry and honour; secondly, in appeals of felony; and thirdly, upon issue joined in a writ of right, the last and most solemn decision of real property. In the two former cases this method of trial may seem natural enough in a military and superstitious age, but the reason or ground of its admission in the last is not so obvious. That usually assigned is the difficulty, in writs of right, of determining the *jus proprietatis;* but another and more plausible pretext for allowing it, in such cases, was for the sake of those claimants who might have the true right, but yet by the death of witnesses or other defect of evidence might be unable to prove it to a jury.

The last trial of battel that was waged in the court of common pleas at Westminster,—though there was afterwards one in the court of chivalry in 1631, and another in the county palatine of Durham in 1638,—took place in the thirteenth year of Queen Elizabeth, A.D. 1571, as reported by Sir James Dyer, and was held in Tothillfields, Westminster, *non sine magna jurisconsultorum perturbatione*, says Sir Henry Spelman, who was himself a witness of the ceremony. In this trial by battel, on a writ of right, the battle was waged by champions, and not by the parties themselves; because in civil actions, if any party to the suit die, the suit must abate, and be at an end for the present; and therefore no judgment could be given for the lands in question if either of the parties were slain. Another reason was, that no person might claim an exemption from this trial, as was allowed in criminal cases. An account of the form and laws of the judicial combat, which are now merely matters of history, may be found in any of the institutional works on English law.

BATTEN, a name given to a plank of wood 7 inches wide, $2\frac{3}{4}$ inches thick, and of length varying from 6 to 50 feet. Battens are now always imported with their length in *even feet;* formerly they were sent cut of all lengths as the tree would allow. When the batten is under 6 feet in length it is styled a *batten end*, but its other dimensions are the same as that of the batten.

BATTERING, the attacking with heavy artillery a fortification or strong post possessed by an enemy, in order to demolish the works.

BATTERING-RAM (*Aries*), a military engine used before the invention of gunpowder, for beating down the walls of besieged fortresses. Generally speaking, it consisted of a long heavy beam of timber, armed at the extremity with iron fashioned something like the head of a ram, which being violently propelled with constant successive blows against a rampart or tower, shook the fabric of masonry, and in time caused it to tumble down.

In its simplest form it consisted of a beam such as we have described, which the soldiers carried in their arms, and with one end of which they assailed the walls by main force. The improved ram was composed of a vast beam, like the mast of a ship, shod with iron at one end, and suspended either by the middle, or from two points, from another beam laid across two posts; and hanging thus equally balanced, it was successively drawn backwards and driven forwards with accumulated momentum against the wall or rampart. This is the kind described by Josephus as having been used at the siege of Jerusalem (*B. J.* iii. 7. § 19). It was also covered over with a roof, shell, or screen of boards, to protect the men employed in working it from the stones, darts, and other missiles discharged by the besieged from the walls; whence it was called *testudo arietaria*. It was also provided with wheels, which greatly facilitated its operations. (Vitruv. x. 19.)

Plutarch informs us that, in the Parthian war, Mark Antony made use of a ram 80 feet in length; and Vitruvius states that this engine was sometimes 106, sometimes even 120 feet in length; a circumstance to which we are to ascribe its prodigious force when vigorously worked. The battering-ram required a century of soldiers at a time to manage it; and as the working parties were regularly relieved as they became exhausted, it was kept in continual action, and from incessant iteration produced the most extraordinary effects. In fact, the momentum of a battering-ram 180 feet in length, 28 inches in diameter, armed with a head of iron weighing a ton and a-half, and moved by the united strength of a hundred men, must have been equal to the momentum of a thirty-six pound shot discharged point blank from a modern piece of heavy ordnance; and hence it is not difficult to conceive how effective the constant reiteration of such impulses would become in the work of demolition.

BATTERY, in the military art, any place where cannon or mortars are mounted, either to attack the forces of the enemy or to batter a fortification. Hence batteries have various names, according to the purposes which they are designed to effect.

Gun-Battery is a defence constructed of earth faced with green sods or fascines, sometimes of gabions filled with earth. It consists of a breastwork, epaulement, or parapet, about 8

Battery. feet in height, and 18 or 20 feet in thickness, with a ditch 12 feet broad at the bottom, 18 at the top, and 7 feet in depth. The open spaces through which the muzzles of the cannon are pointed are called *embrasures*, and the solid masses between the embrasures, *merlons*. The distance from the centre of one embrasure to that of another is 18 feet, and this is also the distance at which the guns are placed from each other; consequently the merlons are 16 feet within and 7 without. The *genouillères*, or those parts of the parapet which cover the carriage of the gun, are generally made 2½ feet in height from the platform to the opening of the embrasures; but this height must be regulated by the semi-diameter of the wheels of the carriage and the nature of the gun. The platforms are plank floors made to prevent the cannon from sinking into the ground, and they are generally 18 feet in length, 15 feet in breadth behind, and 9 feet before, with a rise of 9 or 10 inches from the parapet to check the recoil of the guns, and to render it more easy to bring them forward again when loaded.

Mortar-Batteries differ from gun-batteries in this, that the parapets have no embrasures, and the platforms have no slope, but are exactly horizontal; the shells being fired quite over the parapet, commonly at an elevation of 45°.

Open Battery is a number of cannon, commonly field-pieces, ranged in a row abreast on some natural elevation of ground, or on an artificial bank raised for the purpose.

Covered or *Masked Battery* is when the cannon and gunners are covered by a bank or breastwork, commonly made of brushwood, faggots, and earth.

Sunk or *Buried Battery* is when the platform is sunk or let down into the ground, so that trenches must be cut in the earth opposite the muzzles of the guns, to serve as embrasures to fire through.

Cross-Batteries are two batteries which play athwart each other upon the same object, forming there an angle, and battering with more effect, because what one battery shakes the other beats down.

Battery d'Enfilade is one that sweeps the whole length of a straight line, or the face or flank of any work.

Battery en Echarpe is that which plays obliquely.

Battery de Reverse is one which plays upon the rear of the troops appointed to defend a place.

Camerade Battery is when several guns are discharged upon one point at the same instant.

Redan Batteries are such as flank each other at the salient and re-entrant angles of a fortification.

Ricochet Battery, so called by its inventor Vauban, was first used at the siege of Aeth in 1697. It is a method of discharging cannon with a very small charge of powder, and with just elevation enough to fire over the parapet. When properly managed, its effects are most destructive; for the shot, rolling along the opposite rampart, dismounts the cannon and disperses or destroys the troops. Ricochet practice is not confined to cannon alone; small mortars and howitzers may be effectually employed for the same purpose.

Floating Batteries are such as are erected either on rafts or on the hulls of ships.

Fascine and *Gabion Batteries* are batteries constructed of those machines where sods are scarce, and the earth very loose or sandy. See ARTILLERY.

BATTERY, in *Law*, is the unlawful beating of another. The least touching of another's person wilfully, or in anger, is a battery, for the law cannot draw the line between different degrees of violence, and therefore totally prohibits the first and lowest stage of it; every man's person being sacred, and no other having a right to meddle with it, in any the slightest manner. Upon a similar principle, the Cornelian law *de injuriis* prohibited *pulsation* as well as *verberation*; distinguishing verberation, which was accompanied with pain, from pulsation, which was attended with none. But battery is in some cases justifiable or lawful; Batticaloa || Battle. as where one having authority, a parent or master, bestows moderate correction on his child, his scholar, or his apprentice. It is justifiable on the principle of self-defence; for if one man strike another, or only assault him, the latter may strike in his own defence, and if sued for it, may plead that it was the plaintiff's own original assault which occasioned it. It is likewise justifiable in defence of goods or possession, and in the exercise of an office, as that of church-warden or beadle; but the person pleading such justification in a civil suit, or in a criminal prosecution, must be prepared to instruct that he has observed the *moderamen inculpatæ tutelæ*. By reason of these and other grounds of justification, battery is defined the *unlawful* beating of another; and the remedy is, as for assault, by action of trespass or damages, in which the jury will or ought to give adequate compensation.

BATTICALOA an island within an extensive lagune on the east coast of Ceylon, in Lat. 7.44. N. Long. 81. 52. E. It is of importance on account of the adjacent salt works. The territory of the same name contains a population of 30,000.

BATTIE, or BATTY. See BATNEARS.

BATTLE, a market-town in the rape of Hastings and county of Sussex, 56 miles from London. It is situated in a valley, and consists of one street. This was the scene of the conflict in 1066 which insured to William the Norman the crown of England. The abbey founded by him forms a most magnificent pile of ruins, and the ancient gatehouse is still in good preservation. The place is now celebrated for its gunpowder manufactories. Much business is done at its weekly and monthly fairs. Pop. in 1851, 3849.

BATTLE, an action or engagement between the forces of two armies. A battle is either general or partial; general, where the whole, or the greater part, of each army is brought into action; and partial, where only brigades, divisions, or corps d'armée are engaged. But, however the numbers may vary, the great principles to be applied in delivering battle are in almost every case the same.

It has indeed been said, by a high military authority, that there is nothing invariable in the art of combats; and looking to the endless diversity of circumstances under which battles have been fought, as well as to the apparent results, which are often at variance with the profoundest calculations of science, the observation would seem to have some foundation in truth. But a closer examination will be sufficient to convince us that this is not the case, and that the maxim in question, like many others which pass current in the world, involves a fallacy equally glaring and dangerous. It is no doubt true that, in the circumstances under which battles are fought, there is nothing invariable; on the contrary, it is scarcely possible to suppose two cases, we do not say alike in every particular, but resembling each other even in their great or leading features. From the very nature of things, the data of the problem are variable; but the grand principles by which the solution is to be evolved continue immutably the same. The elements which enter into the calculations of a general are constantly changing; and it is this circumstance which affords scope for the exercise of his genius, his sagacity, and his military science. But it would be manifestly absurd to maintain, that because the conditions are incessantly diversified, the principles of the art experience equal mutations. The issue of battle is always uncertain; because the calculations of the general may be defective, his combinations unscientific, his foresight limited, or his temperament rash and impetuous; and because, even where none of these causes of failure exist, events which no human sagacity could have divined may occur to defeat the wisest plans and the ablest dispositions. But all this implies, that if everything could have been foreseen and provided for, the result would not have been doubtful; and that

Battle. the "grand chances" are always on the side of him who forms his plan with the greatest sagacity, and executes it with corresponding vigour and ability. For, variable as the results of battles appear, the most decisive success has generally crowned the exertions of the greatest commanders; and victory in the long-run has seldom failed to pay homage to science. There is nothing, therefore, invariable in the art of combats, except those principles which science has established as, *mutatis mutandis*, universally applicable.

A battle is not only the most imposing, but also the most important event in war. It is the consummation to which all the previous combinations of commanders necessarily tend; it is that grand act of war which may decide the fate of kingdoms and empires, as well as that of armies and campaigns. The highest and dearest interests of nations, nay even of humanity itself, may be involved in its issue; and the mighty cause of civilization may be accelerated or retarded according as the scales of the battle turn. It cannot, therefore, we should think, be uninteresting or uninstructive, if we endeavour, by recurring to the works of the great masters, to exhibit a condensed digest of those general principles, by the skilful application of which the fate of battles, in all ages, has more or less been determined.

All the combinations of a battle may be reduced to three systems. The first, which is purely defensive, consists in waiting for the enemy in a strong position, without any other object than that of maintaining it against him. Such were the dispositions of Marshal Daun at Torgau, and of the Comte de Marsin in the lines at Turin; dispositions, we may add, which proved wholly unavailing against Frederick and Eugene, and forcibly exemplify the danger of receiving an attack even in the strongest position. The second system, on the other hand, is entirely offensive. It consists in attacking the enemy wherever he can be found, as Frederick did at Leuthen and at Torgau, Buonaparte at Jena and at Ratisbon, and the allied armies at Leipsic. The third system is in some sort a mean term between the first and second. It consists in choosing a field of battle possessing certain advantages both in a strategical and tactical point of view, in order to wait there for the enemy, and, even in the day of battle, to watch the favourable moment for assuming the initiative, and falling upon the adversary with every chance of success. The combinations of Buonaparte at Rivoli and at Austerlitz, and those of Wellington at Waterloo, as well as in the greater part of his defensive battles during the Peninsular war, are examples of the mixed system, and must therefore be classed under this head.

It would be difficult, not to say impossible, to lay down any fixed rules for determining when either of these last two systems, which are the only suitable ones, ought to be employed. Regard must be had to the moral condition of the troops of each party; to the national character, considered as more or less solid or impetuous; and, lastly, to the obstacles presented by the ground. These are circumstances which must always influence the decision of a general; but allowing sufficient latitude for such considerations, the following principles will nevertheless be found generally applicable: 1*st*, That with veteran troops, and in an open country, the absolute offensive or initiative of attack is always most advantageous; 2*dly*, That in ground which, by reason of its physical conformation or other causes, is of difficult access, the better course is to allow the enemy to arrive in a position which has been previously reconnoitred, and to assume the initiative as soon as his troops shall have been exhausted by their first efforts; 3*dly*, That the strategical situation of the two parties may nevertheless sometimes require that the positions of an adversary be attacked by main force, without regard to any local consideration whatever; as, for example, when it is necessary to prevent the junction of two hostile armies, or to fall upon a portion of an army detached, or upon a corps isolated beyond a river. In these and in all similar cases a skilful general will direct an immediate and combined attack, without concerning himself about any consideration extrinsic to the main object of overwhelming the body opposed to him before it can be reinforced. Battle-Axe.

Orders of battle, or the dispositions best suited for conducting troops to the combat, ought to have for their object to insure at once mobility and solidity; and hence they ought neither to be too extended nor too profound. An attenuated order is weak: and troops crowded together in too dense an order are paralyzed; for as the head of the mass only is engaged, disorder is easily introduced, and the enemy's artillery causes frightful ravages. To avoid this double evil, and to fulfil both the conditions of a good order of battle, troops which remain upon the defensive should be partly deployed and partly in columns of battalions, like the Russian army under Beningsen at the battle of Eylau. But troops disposed for the attack of a decisive point ought to be drawn up in two lines of battalions, each of which, instead of being deployed, should be formed in columns by divisions. This order presents infinitely more solidity than a deployed line, the fluctuations of which deprive it of the impulsion necessary for such an attack, and render it impossible for the officers to exercise the necessary control over the troops. Nevertheless, in order to facilitate the march, to avoid too great depth in the mass, and to extend the front without materially lessening the consistence of an army, it may be advantageous to draw up the infantry in two ranks. The battalions will thus possess greater mobility; and, besides, they will have all the force desirable, since the three divisions deployed will possess six ranks in depth, which is more than sufficient; while the extended front will increase in a corresponding ratio the effect of the musketry. In grounds of difficult access, as vineyards, inclosures, gardens, and wooded heights, the defensive order of battle should be composed of battalions deployed, covered by numerous platoons of sharpshooters. But the troops destined for the attack, as well as the reserve, may be advantageously disposed in columns of attack by the centre. The reserve, however, may be kept in part deployed until the moment of advance, in order, by its apparent extent, to impose on the enemy. In a defensive battle upon open ground, squares of battalions may be substituted for columns, by doubling the lines of two ranks so as to form four deep; and each battalion will thus present a sufficient mass, with a front varying from forty to fifty files. This order, which was that employed by the Duke of Wellington at Waterloo, appears advantageous when there is reason to apprehend attacks of cavalry; for it affords at once safety to the infantry, and protection to the cannoneers and train of artillery. But as it has both less mobility and less impulsion than that in columns of attack, the latter has been judged preferable; because, with well-disciplined troops, squares may be easily formed in each battalion by a simple conversion to the right and left of the division of the centre. The Duke of Wellington, it is true, commonly fought deployed; but, to say nothing of the incomparable military qualities of his troops, his lines were generally formed four deep; so that, after all, the exception is more apparent than real.

See Jomini, *Traité des Grandes Opérations Militaires;* Archduke Charles, *Der Strategie;* Rogniat, *Considérations sur l'Art de la Guerre;* Guibert, *Essai Général de Tactique;* Bulow's *Principles of War*, translated by Malortie. (J. B—E.)

Battle-Axe, an ancient military weapon. Axes formed a principal part of the offensive arms of the Celtæ. At the siege of the Capitol by the Gauls under Brennus, one of the most distinguished of their warriors was armed with a battle-axe; and Ammianus Marcellinus, many centuries afterwards, describing a body of Gauls, states that all of them were armed with battle-axes and swords. Some of these

Battlement || Baudius.

weapons have been found in the sepulchres of the ancient Britons on the downs of Wiltshire and in the north of Scotland. Four or five centuries ago the Irish went constantly armed with axes. On the morning of the battle of Bannockburn, King Robert the Bruce cleft an English warrior to the chin with one blow of his battle-axe. The Lochaber axe remained long a formidable weapon in the hands of the Scottish Highlanders; and it was the principal weapon of the City Guard of Edinburgh till the year 1817, when that body was abolished.

BATTLEMENT. See ARCHITECTURE, *Glossary*.

BATTORY, a name given by the Hans Towns to their magazines or factories abroad.

BATTU, an island lying off the western coast of Sumatra, 40 miles in length by 10 in average breadth, and entirely covered with wood. It is almost immediately under the equinoctial line. Its exports are cocoa-nuts, oil, and sea-slugs.

BATTUE, a French word in common use among sportsmen to denote the practice of beating the bushes in order to start the game, or to drive it within circumscribed limits.

BATUM, a seaport town of Asiatic Turkey, in the pashalic of Trebizonde, and 110 miles N.E. of the town of that name. It is situated on the Black Sea, at the mouth of the river Tchorak. Its harbour is safe and commodious. A British vice-consul resides there. Pop. about 3000.

BAUCIS and PHILEMON, in *Fabulous History*, an aged couple who dwelt in a cottage in Phrygia. Jupiter and Mercury, disguised as mortals, were well received by this venerable pair, after having been refused entertainment by every body else. To punish the people for their inhumanity, they laid the country under water, but removed Baucis and Philemon to the top of a mountain, where they saw the deluge, and their own little hut above the waters changed into a temple. Here the grateful gods promised to confer on their entertainers whatever boon they might solicit. They expressed a desire to officiate in this temple as priest and priestess, and to die at the same moment; both of which requests were granted. Ovid, *Met.* viii.

BAUDELOCQUE, JEAN-LOUIS, an eminent French surgeon and accoucheur, appointed by Napoleon to attend the Empress Maria-Louisa in the latter capacity. He was the author of *L'Art des Accouchements*, and numerous other works on the diseases of women and children. He died in 1810, aged sixty-four.

BAUDELOT DE DAIRVAL, CHARLES-CÉSAR, a learned advocate in the parliament of Paris, distinguished by his skill in ancient monuments. He wrote a *Treatise on the Advantages of Travelling; Letters and Dissertations on Medals*, &c. He was admitted into the *Academie des Inscriptions* in 1705, and died in 1722, aged seventy-four.

BAUDIER, MICHEL, a gentleman of Languedoc, who lived in the reign of Louis XIII., and published several copious and laborious historical works. Among these were, *An Inventory of the General History of the Turks; History of the Seraglio and Court of the Sultan; History of the Religion of the Turks; History of the Court of the King of China; The Life of Cardinal Ximenes*, &c. The latter is considered the most valuable of his works. He died in 1645.

BAUDIUS, DOMINICUS, professor of history in the university of Leyden, was born at Lisle in 1561. He studied at Aix-la-Chapelle, at Leyden, and at Geneva, and was admitted doctor of law in 1585. Soon after he accompanied the ambassadors from the states to England, where he became acquainted with several persons of distinction, particularly the famous Sir Philip Sidney. He was admitted advocate at the Hague in January 1587; but becoming weary of the bar, he went to travel in France, where he remained ten years. In 1592, Achilles de Harlai, first president of the parliament of Paris, obtained for him the appointment of advocate of the parliament of Paris. In 1602 he went to England with Christopher de Harlai, the president's son, who was sent as ambassador to England by Henry the Great. In the course of the same year he was made professor of eloquence at Leyden, and settled in that university. In 1611 the states conferred upon him the office of historiographer in conjunction with Meursius; and in consequence of this appointment he wrote *The History of the Truce*. The disgrace he brought on himself by his irregular life is said to have hastened his end. He died at Leyden in 1613. As a Latin writer, both in prose and verse, Baudius was excelled by few of his contemporaries.

Baugé || Bauhin.

BAUGÉ, an arrondissement, department of Maine and Loire, in France, comprehending six cantons and sixty-six communes. Area 543 square miles; pop. 79,713. The chief place of the same name is situated on the river Couanon; pop. in 1851, 3147, principally employed in making serges and other woollen goods.

BAUGE, a drugget manufactured in Burgundy of thick spun thread and coarse wool.

BAUHIN, JEAN, a distinguished botanist, born at Basle, in 1541. He was the son of an eminent physician, who quitted France, his native country, on account of religion, and settled at Basle. In early life he travelled with Gesner, the celebrated naturalist, and collected plants in the Alps, in France, and in Italy, for the great botanical work which he afterwards accomplished. He first practised medicine at Basle, where he was elected professor of rhetoric in 1566. He then resided for some time at Yverdun; and in 1570 was invited to be physician to the Duke of Wirtemberg at Montbelliard; a situation in which he spent the remainder of his life. He devoted his time chiefly to botany, on which he bestowed great labour. He likewise prosecuted other branches of natural history, and published an account of *Medicinal Waters throughout Europe*. His great work on plants was not completed at his death, which happened in 1613. A society at Yverdun published in 1619 the *Prodromus;* but it was not till 1650 and 1651 that the work itself appeared, in three vols. folio, entitled *Historia Plantarum nova et absolutissima, cum Auctorum consensu et dissensu circa eas*. This performance, with all its defects, has been pronounced by Haller to be without an equal. It is still considered a standard work; and the names of John Bauhin and his brother rank high among the founders and first promoters of botanical science.

BAUHIN, *Gaspard*, brother of the former, was born at Basle in 1560. He was early devoted to physic, and pursued his studies at Padua, Montpellier, and some of the celebrated schools in Germany. In his journeys he collected a number of plants which had escaped his brother's notice. Returning to Basle in 1580, he was admitted to the degree of doctor, and gave private lectures in botany and anatomy. In 1582 he was appointed to the Greek professorship in that university, and in 1588 to the chair of anatomy and botany. He was afterwards made city physician, professor of the practice of medicine, rector of the university, and dean of his faculty. Haller gives him the character of being assiduous and laborious in collecting plants, by which means he surpassed his brother in the number of them, as he also did in the accuracy of his figures; but he possessed less acuteness of judgment in distinguishing varieties, and in detecting the same species under different names. He published several works relative to botany, of which the most valuable is his *Pinax Theatri Botanici, seu index in Theophrasti, Dioscoridis, Plinii, et botanicorum qui a seculo scripserunt opera, plantarum fere sex millium nomina, cum synonymiis et differentiis. Opus XIV. annorum*, 4to. The confusion that began to arise at this time from the number of botanical writers who described the same plant under different names, rendered such a task as this highly necessary; and though there are many defects in the execution, the *Pinax* of Bauhin is still a useful key to all the writers before his time. An-

Baumans Höhle. || Baumé.

other great work which he planned was a *Theatrum Botanicum*, meant to be comprised in twelve parts folio, of which he finished three; only one however was published. He also gave a very copious catalogue of the plants growing in the environs of Basle; and edited the works of Matthiolus with considerable additions. He likewise wrote on anatomy: his principal work on this subject is *Theatrum Anatomicum infinitis locis auctum*, 4to, Frankf. 1621; which is a kind of *pinax* of anatomical facts and opinions. He died in 1624.

BAUMANS HÖHLE, a celebrated series of natural caverns, described and figured by Leibnitz in his *Protogæa*. They obtained this name from an unfortunate miner who, in 1670, ventured to explore the cave, and being there lost for three days and nights, died of exhaustion soon after escaping from its recesses. The cave is in a bed of limestone of transition, about two miles from the town of Elbingrade, and 18 from Goslar. The entrance is 15 feet wide, and 5 feet high; and leads by a rapid descent to a grand chamber, between 40 and 50 feet in diameter, and from 10 to 20 feet in height. From the roof depend stalactites; and the floors of the cavern have been all covered with stalagmite, much broken up in the search for the fossil bones that abound there. The bones, like those in other German caves, are those of the fossil elephant, rhinoceros, bear, hyæna, &c., imbedded in mud and sand mixed with water-worn pebbles. This detritus incloses the antediluvian bones, but the human bones found in this and other similar caves have evidently a more recent origin, being the remains of persons who have accidentally perished there. (Leibnitz, *Protogæa;* Buckland's *Reliquiæ Diluvianæ.*) (T. S. T.)

BAUMÉ, ANTOINE, a Parisian apothecary, distinguished by his knowledge of chemistry, and by his practical application of that knowledge, was born at Senlis in 1728. He was the son of an innkeeper, and was put as apprentice to the eminent chemist Geoffroy. He had to contend with the disadvantages of a defective education; yet he nevertheless prosecuted his scientific researches with great success. In 1752 he was admitted a member of the College of Pharmacy; soon after he was appointed professor of chemistry at that establishment; and in his lectures he displayed the excellent arrangement which is seen in his published works. He carried to a great extent his commercial establishment in Paris for the preparation of drugs for medicine and the arts, such as the acetate of lead, the muriate of tin, mercurial salts, and antimonial preparations. At the same time he published a number of papers on chemical science, and on arts and manufactures. He established the first manufactory of sal-ammoniac in France, a substance which before that time had been obtained from Egypt. He was the first also who devised and set on foot a process for bleaching raw silk. Having acquired a competency by the success of these different undertakings, he retired from trade, and devoted his time to the application of chemistry to the arts. He improved the process for dyeing scarlet at the manufactory of the Gobelins, and published a cheap process for purifying saltpetre. By the revolution he lost his fortune, but this calamity, instead of disheartening him, stimulated him to resume his trade. He was chosen a correspondent of the Institute in 1796, and died in 1804, at the age of seventy-six. He was temperate, active, and regular in his habits. Many of his papers are published in the *Memoirs of the Academy of Sciences*. Of his separate publications, the following may be mentioned here: *Dissertation sur l'Ether*, in 12mo; *Plan d'un Cours de Chimie Expérimentale*, 1757, in 12mo; *Opuscules de Chimie*, 1798, in 8vo; *Elémens de Pharmacie Théorique et Pratique*, 2 vols. 8vo; *Chimie Expérimentale et Raisonnee*, 3 vols. 8vo, 1773.

Baumgarten || Bautzen.

BAUMGARTEN, ALEXANDER GOTTLIEB, an eminent German philosopher, born at Berlin in 1714. He pursued his studies at Halle, and afterwards became professor of philosophy at Frankfort on the Oder; in which city he died in the year 1762. He was a disciple of Leibnitz and Wolf, and was particularly distinguished for his æsthetical speculations, having been the first to develop and establish the *Theory of the Beautiful* as an independent science. Baumgarten, however, cannot properly be regarded as the founder of æsthetics. Plato, in the Phædrus and the Hippias, had already made the Beautiful the object of a special analysis, and though confounding the two qualities of *goodness* and *beauty*, the profoundness of his speculations has thrown into the shade Baumgarten and all the other followers of Wolf who have pursued the same subject. The very name (*Æsthetics*) by which Baumgarten distinguished the science of the Beautiful, though now very generally adopted for the sake of convenience, indicates the imperfect and partial nature of his analysis, pointing as it does to an element so variable as *feeling* or *sensation* as the ultimate ground of judgment in questions pertaining to beauty. Yet the labours of Baumgarten will only be contemned by those who deny the possibility of a science of æsthetics. The principal works of Baumgarten are the following: *Disputationes de nonnullis ad poema pertinentibus; Æsthetica; Metaphysica; Ethica philosophica; Initia philosophiæ practicæ primæ.*

BAUR, JOHANN WILHELM, an eminent Flemish painter, and a disciple of Brendel. He spent some time at Rome, where his studies were wholly devoted to architecture and landscapes. He painted small figures in distemper on vellum, and etched with great spirit. His largest works are historical. He was born at Strasburg in 1600, and died at Vienna in 1640.

BAUTZEN, or BUDISSIN, one of the four provinces into which the kingdom of Saxony is divided, comprehends the greater part of Upper Lausatia, the rest of which, together with Lower Lausatia, was ceded to Prussia in 1815. It has an area of 970 square miles, and is divided into the districts of Bautzen, Camenz, Löbau, and Stolpen; containing 14 cities, 658 villages and hamlets: pop. in 1851, 290,589. See SAXONY.

BAUTZEN, the capital of the above province, occupies an eminence on the right bank of the Spree, 680 feet above the level of the sea, and 32 E.N.E. from Dresden. The town is well built, and has extensive suburbs partly lying on the left bank of the river. It has a cathedral, which is used by both Protestants and Roman Catholics; five other churches, a handsome town-house, an orphan-asylum, several hospitals, mechanics' institute, gymnasium, a normal and several other schools, and two public libraries. Its general trade and manufactures are considerable, including linen, cotton, and woollen goods, tobacco, leather, paper, gunpowder, &c. Pop. (1849) 10,518. The battle of Bautzen was fought here on the 21st and 22d of May 1813, between the French under Napoleon and the allied forces of Russia and Prussia; in which, after a severe loss on both sides, the latter were defeated. Lat. 51. 11. 10. N. Long. 14. 25. 50. E.

BAVARIA,

Bavaria. A COUNTRY in southern Germany, in former times a margraviate and duchy, afterwards an electorate, and, since 1806, a kingdom of considerable extent. It is situated between the forty-seventh and fifty-first degrees of N. Lat. and is of an oblong form, its greatest extent being from N. to S. Its breadth is different in different parts, but we may form a tolerably correct idea of the whole by supposing a rectangular tract of country, of 200 miles in length by 140 in breadth. Such a tract would contain a surface equal to the Bavarian territory, exclusive of the distant province on the Rhine; including that province, however, the extent of the kingdom is nearly 30,000 square miles, or somewhat greater than that of Scotland.

Extent.

History. The name in German, Baiern, is derived, like its old Latin name Boiaria, from Boii, the name of a people of Celtic origin, who were the inhabitants of this country in the reign of Augustus. It then formed part of the Rhætia Vindelicia and Noricum of the Romans. After the fall of the Roman power, the natives were governed by military chieftains of their own till the era of Charlemagne, who succeeded in subjugating this as well as most other parts of Germany. After his death, Bavaria was governed by one of his grandsons, whose successors bore the title of Margrave, or Lord of the Marches. In the year 920 the ruling margrave was raised to the rank of duke, which continued the title of his successors for no less than seven centuries. During this long period Bavaria was connected with Germany, nationally by language, and politically as a frontier province, but in civilization was almost as backward as Austria, and greatly behind Saxony, Franconia, and the banks of the Rhine. At last, in 1620, a formidable insurrection taking place in Bohemia against Austria, the reigning Duke of Bavaria sided with the latter, and having rendered great service to her cause, received an important accession of territory, and was appointed one of the nine electors of the empire. His successors continued faithful members of the Germanic body and allies of Austria until the ambitious projects of Louis XIV. of France led, in the year 1702, to a close connection between that monarch and the elector; the object of which was to threaten and even attack Austria, so as to prevent her from co-operating efficiently with England and Holland in their great contest with France. This hostile attitude of Bavaria, joined to the insurrectionary movements in Hungary, bore so hard on the emperor as to induce the Duke of Marlborough, in the spring of 1704, to march his army above 300 miles from the banks of the Maese to those of the Danube and Iser. Bavaria was now invaded, and the elector put under the ban of the empire; but he remained firm to his alliance with Louis, and a French army under Marshal Tallard advanced from the Rhine to his relief. It was over this army, joined to a strong Bavarian force, that Marlborough and Prince Eugene obtained the signal victory of Blenheim, on the 13th August 1704. The result was decisive of the fate of the electorate; the French fled to the Rhine; the elector fled with them, and Bavaria was governed by commissioners appointed by the emperor. This state of things lasted ten years; the elector and his remaining military force serving in the French armies, until the peace of Utrecht, or more properly that of Baden, in 1714, reinstated him in his dominions.

The son and successor of this elector, untaught by the disasters of his father, was induced to renew his connection with France; and, in 1740, on the death of the Emperor of Germany, he ventured to come forward as a candidate for the imperial crown. In this he succeeded so far as to be named to that high dignity by a majority of the electors, and to overrun a considerable part of the Austrian territory; but his triumph was of short duration, for the armies of Maria Theresa, aided by English subsidies, came forward in superior numbers, and not only repulsed the Bavarians, but obtained, in 1744, possession of the electorate. The elector died soon after, and his son recovered his dominions only by renouncing the ambitious pretensions of his father.

Bavaria. Bavaria.

Bavaria now remained tranquil above thirty years, until 1778, when, by the death of the reigning elector, the younger line of the house of Wittelsbach, the line which had long ruled in Bavaria, became extinct. The next heir was the Elector Palatine, the representative of the elder line of the family of Wittelsbach; but Austria unexpectedly laid claim to the succession, and took military possession of part of the country. This called into the field, on the side of Bavaria, Frederic II. of Prussia, then advanced in years. The armies on each side were formidable and well commanded; they made many threatening marches and countermarches, but happily no bloodshed took place; and at last Austria desisted from her pretensions, on obtaining from Bavaria the cession of the frontier district called the Innviertel, or Quarter of the Inn.

Bavaria again remained at peace for many years, until the great contest between Germany and France began in 1793, when she was obliged to furnish her contingent as a member of the empire. During three years her territory was untouched, the operations being carried on in the Netherlands and on the Rhine; but in the summer of 1796, a powerful French army under Moreau advancing and occupying her capital, the consequence was a separate treaty with France, and the withdrawal of her contingent from the army of the empire. The next war between France and Austria, begun in 1799, was comparatively short; but ending disastrously for the latter, the influence of France in the empire was greatly strengthened, so that, in 1805, when the Austrians, subsidized by England, once more took up arms, Bavaria was the firm ally of France, and for the first time found advantage in the connection. In the short space of three months, the victories of Ulm and Austerlitz enabled Buonaparte to prescribe the conditions of peace, and to confer on his electoral ally the title of king, along with very considerable additions of territory.

These substantial acquisitions rendered Bavaria the willing assistant of France in the invasion of Prussia in the subsequent autumn. The battle of Jena took place, and a further increase of territory to Bavaria followed at the peace of Tilsit. The consequence was, that in 1809, when the absence in Spain of a great part of the French military force encouraged Austria again to try the hazard of war, the Bavarian troops were wholly at the disposal of Buonaparte, and formed a main part of the great army with which he defeated the Austrians at Eckmuhl and Wagram. The peace that ensued gave a further aggrandizement to Bavaria; but a few years more showed how dearly it was purchased, when many thousands of her best troops perished in the disastrous retreat from Russia. This sacrifice of lives, and the horror of Buonaparte's tyranny, excited in Bavaria, as in the rest of Germany, an ardent wish to throw off his yoke. Nor was opportunity long wanting. In the following year (1813) the allied sovereigns advanced into Saxony, and gave assurance to the king of Bavaria, that, in the event of his co-operating vigorously with them against France, he should be maintained in all his late acquisitions. The king received these assurances with satisfaction, but could not in prudence join the allies for some months; at the end of which the retreat of the French from Dresden, and the probability of their falling back to the Rhine, induced him to make an open declaration of hostility against his former allies,

Bavaria. and to march an army to Hanau, on the Maine, the line of their expected retreat. At Hanau, accordingly, in the latter days of October, several obstinate conflicts took place between the Bavarians and the French; and although the latter forced their way, it was with considerable loss. From that time forward Bavaria took a decided part against Buonaparte, and was confirmed in her extended territory by the definitive treaties of 1814 and 1815. She ceded to Austria her ancient possession of the Tyrol, but received equivalents in Franconia and the vicinity of the Rhine.

The duchy of Bavaria, or the country which was subject to the dukes during the middle ages, and before they were raised to the rank of electors, was the southern half of the present kingdom, and lay almost all to the south of the Danube. This is the Bavaria of our old maps, nearly square in its form, extending about 100 miles from the Danube to the Tyrol, and somewhat more from Suabia on the west to Austria on the east. To this limited territory an important addition was made after 1620, at the expense of the Elector Palatine, who having taken an active part in the great insurrection in Bohemia against Austria, forfeited both his title and his dominions to the Duke of Bavaria. His dominions consisted of what was called the Upper Palatinate, a province of full 3000 square miles, situated to the north of the Danube. This country, joined to the duchy of Bavaria, constituted during a century and a half (from 1623 to 1778) the dominions of the elector; their territorial extent being about 15,000 square miles; and their population, in the beginning of that period, less than 1,000,000, but towards its close about 1,500,000.

In 1778 the succession of the Rhenish branch of the reigning family added to the former territory of Bavaria the palatinate of the Rhine, a district of no great extent, but fertile and populous. By this time the nation, hitherto illiterate and backward, became fit for improved institutions, and was fortunate in the character of two successive rulers. She was thus increasing gradually her productive industry and political weight, when, in 1806, her progress received a sudden impulse from political causes. Buonaparte had long laboured to weaken the ascendancy of the greater over the lesser states of the empire; and in 1806 the overthrow, first of Austria, and afterwards of Prussia, enabled him to make a very large addition to the territory of his German allies, above all of Bavaria. This was obtained chiefly in Franconia, a country which, being contiguous to Bavaria, and similar to it in soil and climate, is, in general, more advanced both in agriculture and manufactures. The valuable districts of the Lower Maine and the Rezat, with part of those of the Upper Maine and Upper Danube, were all obtained on this occasion; not to mention the Tyrol, which was afterwards restored to Austria.

Present Divisions of the Kingdom, with their Areas and Populations in December 1852.

Old Circles.	New Circles.	Area in English square miles.	Families.	Males.	Females.	Total.
Iser	Up. Bavaria	6,595	158,059	369,409	365,422	734,831
Lower Danube	Lower Bavaria	4,124	114,347	270,082	279,514	549,596
Rhine	Palatinate	2,243	126,812	303,398	308,078	611,476
Regen	Up. Palatinate	3,700	107,241	223,951	244,528	468,479
Upper Maine	Up. Franconia	2,699	122,506	242,215	257,494	499,709
Rezat	Mid. Franconia	2,919	117,599	257,243	276,587	533,830
Lower Maine	Low. Franconia	3,593	117,614	293,138	302,610	595,748
Upper Danube	Suabia	3,687	132,169	274,656	291,127	565,783
	Total	29,560	996,347	2,234,092	2,325,360	4,559,152

Bavaria. The dense population of the circles of the Rezat and Lower Maine clearly shows the value of the territory acquired in Franconia; while the comparative thinness of inhabitants in the departments of the Regen and Iser proves the inferior soil of the Upper Palatinate, and of the southern or mountainous part of Bavaria. Similar conclusions are suggested by the following sketch of the respective proportions of the soil which lie waste or are in a state of cultivation. It must, however, be considered as only an approximation to the different proportions of land in the kingdom.

Proportions of 100.

Circles.	In Tillage and Pasture.	Forest Land.	Waste.
Rezat	70	22	8
Upper Maine	60	29	11
Lower Maine	58	32	10
Rhine	57	36	7
Lower Danube	50	29	21
Upper Danube	50	25	25
Regen	47	30	23
Iser	35	31	34
Average of the kingdom	53	29	18

Forests. The extent of forest land in Bavaria is double that of the forest land of France, and more than six times that of the land under wood in Great Britain. This is owing to various causes; the great extent of hilly and mountainous country, the insufficient population, and the necessity of keeping a given extent of ground in wood for a supply of fuel. There are, besides, many spots and even districts in the forest lands which are under cultivation for flax, corn, and potatoes. The forests are partly public, partly private property. The gross annual value of the former amounts to nearly L.350,000, but from the heavy expense attending their management, the net value to the state amounts to little more than half that sum.

Mountains. The frontier of Bavaria on the north-east, towards Bohemia, consists of a long range of mountains; and there are also very extensive chains in the neighbouring part of Franconia. These, however, seldom exceed the height of 3000 or 4000 feet; but the ridges in a very different part of the kingdom,—those namely on the south, which separate it from the Tyrol,—partake of all the grandeur of the Alps, several of them being from 9000 to 10,000 feet in height; an elevation approaching to that of Ætna, and more than double that of the highest mountains in Scotland.

Lakes and rivers. There are numerous lakes in Bavaria, particularly in the mountainous parts. In the low country there are several extensive tracts of marshy ground, as in all half-cultivated countries. Of the rivers of Bavaria the most remarkable is the Danube, which, on entering the frontier from Suabia, is of sufficient size to be navigable, and afterwards traverses the whole breadth of the kingdom, making with its windings a course of 200 miles. In this long space it becomes increased by the successive junction of the Iller, the Lech, the Iser, and the Inn, all flowing northward from the Alps. On the north or Franconian side, the Danube receives the Nab, the Altmuhl, and several smaller streams. Though a considerable river even in this early part of its course, it is not large enough to make the erection of bridges a work of so great labour as after the influx of the Inn; so that there are no less than sixteen bridges across the Danube in the course of its passage through Bavaria.

The Inn takes its rise in Switzerland, flows through the Tyrol, and being early swelled by the mountain streams to the right and left of its course, is navigable before it enters the Bavarian territory. It then holds a north and north-east course, and receives the Salsa, a large river flowing from Upper Austria; after which their united waters, between 200 and 300 yards in breadth, fall into the Danube

Bavaria. at Passau. The Iser or Isar has its source in the Tyrolese Alps, flows in a curved direction nearly north-east, passes Munich, becomes navigable, and, after receiving several tributary streams, falls into the Danube half-way between Ratisbon and Passau. The Lech has a similar course, but of less length. In the northern part of the kingdom the Maine is the only river of consequence, either for size or for extent of navigation. It traverses Franconia with a very winding course, and greatly facilitates the trade of that province.

Climate. The climate of Bavaria is in general healthy, although the degree of heat, in this as in the neighbouring country of Austria, is very different according to local differences in the elevation of the soil: hence the cold of Upper Bavaria in the vicinity of the Tyrol, and the warmth of the plains adjoining the Danube and the Maine. On the whole, the temperature of Bavaria is considerably colder than that of England in the winter months, and considerably hotter during the summer and autumn.

Products. The extent of forest land in every province of Bavaria is such as to supply a great quantity of wood for sale; but the transport of it is in many parts difficult, from the badness of the roads, and on account of the distance from navigable rivers. The forests are chiefly on the hills and mountains; and the level country, as well Lower Bavaria extending northwards to the Danube, as the western and middle parts of Franconia, is very productive in wheat, barley, rye, oats; also in hemp, flax, hops, madder, and, in warm situations, in vines. The last are raised chiefly in the vicinity of the lake of Constance, and on the banks of the Maine in the lower part of its course. On the whole, the best cultivated districts are those in which the descent of streams from the high grounds gives facilities to irrigation. Such is the case in the valley of the Danube and in part of the plains of Franconia; but in most other parts of the kingdom a great part of the arable land still remains uncultivated. The quantity of potatoes raised annually in the kingdom has been much increased in the last and present age, particularly in the northern provinces. The Spessart, an extensive tract of forest land in Franconia, formerly neglected, is now rendered very productive in this respect. That much remains to be done before justice is rendered to the soil, is evident, since, with a climate fully as good as ours, and a soil inferior only in the mountainous parts, the average population of Bavaria is not one-third that of England. The government has caused a few of the marshes to be drained; but these are merely incipient operations, and but an inconsiderable part of what ought before this time to have been performed.

Pasture lands. The proportion of land under pasture appears to be nearly the same in one circle or province as another. According to the most recent return, the number, of horses in the kingdom in 1840 was 349,688; cattle, 2,625,294; sheep, 1,889,888; swine, 842,851; and goats, 107,236. Little attention has as yet been given to the improvement of the breed of horses or oxen; but in sheep considerable progress has been made in adopting that improved treatment which has added so largely to the value of the wool of Saxony.

Minerals. The quantity of salt prepared annually in Bavaria is very considerable. The gross produce in each of the three years from 1844 to 1847 amounted severally to 5,033,122, 5,127,057, and 5,237,369 florins; and the net produce to 2,481,276, 2,463,954, and 2,439,543 florins. It is obtained partly from brine springs in the circle of the Iser, partly from salt mines at Halle and other parts; which, like most undertakings of magnitude on the Continent, are, and must, from want of capital on the part of individuals, be wrought on account of the government.

In so mountainous a country the quantity of iron ore is naturally very large. The mines are numerous, but they are on a small scale compared with those of this country. The number of forges at work in 1847 was 169, with 3238 workmen. These mines are found in various parts of the kingdom; in the mountains of Franconia, as well as in those of the south of the kingdom. The coal mines are in like manner numerous, but of small extent compared with ours; the yearly produce of the mines in the Bavarian dominions being only from 60,000 to 70,000 tons. Of quicksilver there are several mines, chiefly in the province of the Rhine. Small quantities of copper, manganese, cobalt, and mercury, are obtained in Rhenish Bavaria. There are numerous quarries of excellent marble, alabaster, gypsum, and building stones; and the porcelain clay is among the finest in Europe. Bavaria.

The population of Bavaria is principally agricultural. Of the 959,099 families and 4,370,977 inhabitants in the kingdom in 1840, 605,693 families and 2,869,702 persons belonged to the agricultural population; the remainder representing the commercial, industrial, and mining portion of the inhabitants.

Manufactures. Manufactures are as yet very backward, even in articles such as hardware, for which the raw material is supplied on the spot. Woollens, linens, and in some towns cottons, are made, but of a quality much coarser than the corresponding manufactures of England, or even of the Netherlands. There are a number of mills in Franconia for making paper, in consequence of two very distinct causes, the frequency of water-falls and the cheapness of linen rags. The extent of the forests, and the command of water-power, have led to the erection of many saw-mills; there being no less than 3366 in the kingdom in 1847. Of glass also the quantity annually made is considerable. As to liquor, the climate of Bavaria being in many parts too cold for the grape, beer is the general drink, and the breweries are very numerous. There are upwards of 5000 breweries in the kingdom, employing about 12,000 workmen. They are not, as in England, confined to the large towns: in a country where the means of carriage by water are so limited, they are necessarily established in almost every district. The other principa. articles of manufacture are leather, tobacco, and earthenware.

Trade. The exports from Bavaria are such as may be expected in a country chiefly agricultural: they consist of salt, timber, cattle, pigs, corn, and madder. The imports consist of sugar, tobacco, cottons, silks, with some woollens, and linen of the finest qualities. The yearly value of the exports is about two millions sterling; that of the imports nearly the same. The government, desirous of removing whatever is pernicious in established usages, abolished, in 1827, the privileges of guilds and corporations; but it must do a great deal more before trade can be raised to a flourishing condition.

Roads, &c. The high roads in Bavaria extend in all over 5500 miles. In 1850 there were about 290 miles of railway in operation. The principal line is that extending from Kaufbeuern to Hof, and thence to Leipzig, traversing nearly the entire length of the kingdom from south to north, and passing in its course through Augsburg, Nuremberg, and Bamberg. A branch of this line proceeds from Augsburg to Munich, and another from Nuremberg to Fürth. The principal canal of Bavaria is the Ludwigs canal recently completed, and which is likely to become one of the most important in Europe. It connects the Rhine with the Danube, and extends from Bamberg on the Regnetz to Dietfurt on the Altmühl.

The increase of the population of Bavaria has been regularly and even rapidly progressive since the beginning of the present century. The following table shows its population in 1818, 1827, and 1846; that of 1849 has already been given. The births during the year 1843–4 were 76,110 males, and 71,256 females (exclusive of 4300 still-born); marriages, 29,490; deaths, 125,382. The immigrants dur-

Bavaria.

ing that period amounted to 972, and the emigrants to 5854, of whom 4104 were to America.

Increasing population.

	1818.	1827.	1846.
Upper Bavaria	585,467	637,299	705,544
Lower Bavaria	450,895	483,741	543,709
Palatinate	446,168	517,081	608,470
Upper Palatinate	403,481	432,165	467,606
Upper Franconia	394,954	437,473	501,163
Middle Franconia	437,838	476,316	527,866
Lower Franconia	501,212	542,475	592,080
Suabia	487,951	518,019	558,436
	3,707,966	4,044,569	4,504,874

The chief towns.

The following gives the principal towns of the several circles, with their populations in 1846:—

		Pop. in 1846.	Order of importance.
Upper Bavaria	Munich	94,830	1
	Ingolstadt	10,285	13
Lower Bavaria	Passau	11,275	10
	Landshut	10,354	12
	Straubing	9,698	16
Upper Palatinate	Ratisbon	23,948	5
	Amberg	10,225	14
Upper Franconia	Bamberg	21,074	6
	Baireuth	17,358	7
	Hof	8,728	17
Middle Franconia	Nuremberg	50,460	2
	Fürth	15,842	8
	Ansbach	12,254	9
	Erlangen	10,770	11
	Eichstädt	7,587	20
	Schwabach	7,125	21
	Rottenburg	5,170	25
	Dinkelsbuhl	5,053	26
Lower Franconia	Wurzburg	29,147	4
	Aschaffenburg	9,815	15
	Schweinfurt	7,660	19
Suabia	Augsburg	38,206	3
	Kempten	8,395	18
	Memmingen	6,821	22
	Neuburg	6,680	23
	Nordlingen	6,523	24
	Lindau	4,470	27
	Kaufbeuern	4,234	28

Spire, the chief town of the palatinate, has a population of about 19,000.

The palatinate or circle of the Rhine is wholly detached from the rest of the kingdom, being nearly 100 miles to the westward, and having the Rhine on the east, Rhenish Prussia and Hesse-Darmstadt on the north, Rhenish Prussia and Hesse-Homburg on the west, and France on the south. This province is an oblong of nearly 55 miles by 40; its extent is 2243 square miles, and its population (see the foregoing table) more dense than that of any other part of the kingdom. Its surface is very uneven, for the Vosges Mountains extend over a part of its territory. In these there are extensive pastures, and, in some places, mines of iron, coal, and quicksilver. In the low grounds the products are wheat, oats, barley, and, in the warmer situations, vines. This province, equal in extent to two of our middle-sized counties, is divided into twelve districts and thirty-one cantons; of which the chief towns are Spire, Landau, Deux Ponts, and Kaiserslautern. After the great successes of the French in 1794 and 1795, this district, formerly the palatinate of the Rhine, became, along with the whole country to the left of the Rhine, subject to France, and so remained for nearly twenty years, until the overthrow of Buonaparte in 1814. At that memorable juncture it was assigned by the congress of Vienna to Austria, and made over by the latter to Bavaria in the subsequent exchanges.

Bavaria. The Rhenish Province.

It may be proper to explain here what was meant by the Circle of Bavaria, although, like the other circles of the empire, it has now ceased to have a political existence. It comprised the territories of the elector of Bavaria, as well as of a number of contiguous petty states, whose respective princes were members of the Germanic body. In addition to Bavaria Proper and the Upper Palatinate, the circle comprised the archbishopric of Salzburg and a number of lesser principalities, which are now mediatized or blended with their greater neighbours; but it contained no part of Franconia, which was a circle by itself. The extent of the circle of Bavaria was about 17,000 square miles, and its capital was Ratisbon. That city was also the residence of the dukes of Bavaria until the fourteenth century, when the acquisition of the upper country towards the Tyrol induced them to fix their residence at Munich.

Former circle of Bavaria.

According to the budget for the financial period from 1849 to 1855, the net annual revenue was fixed at 33,649,799 florins, or L.2,944,357, and the expenditure at 33,675,960 florins, or L.2,957,872. The national debt in 1851 amounted to 136,995,620 florins, or L.11,987,117.

Bavaria. Army.

The military force of Bavaria is raised, as in most of the other German states, by conscription, each conscript being subject to four years' service. The nobility and clergy are exempted, and generally also students and persons indispensable to the maintenance of their families. Besides the permanent army, there is a reserve destined to reinforce it; and in the event of war, the militia, composed of all the males between nineteen and sixty, except the nobility and clergy, may also be called out in aid of the army, but only in the interior. The infantry consists of sixteen regiments of 3080 men each, with six battalions of *chasseurs* having each 907 men, making a force of 54,722 men. The cavalry is composed of two regiments of cuirassiers, and six regiments of light horse, in all 9784. The artillery corps consist of 8130; the sappers, miners, and pontoneers of 1039; and the gendarmerie of 2289 men. The entire force of Bavaria therefore numbers about 76,000 men, but of these a large proportion is generally absent on furlough. It furnishes to the Germanic confederation a contingent of 35,600 men.

The military school at Munich has a high reputation. Arms and ammunition are manufactured in different towns in the kingdom.

Religion.

Christianity appears to have been introduced into Bavaria in the sixth century. The proportion of the different religions in 1840 was as follows:

Roman Catholics	3,060,694
Lutherans	1,181,216
Calvinists	2,717
Jews	59,288
Moravians, Anabaptists, and lesser sects,	4,836
	4,308,751

The exercise of religious worship in Bavaria is altogether free. The Protestants have the same civil rights as the Catholics, and the sovereign may be either Catholic or Protestant. Civil immunities have not yet been extended to Anabaptists, Moravians, or Jews. The latter, as in other countries, follow neither agricultural nor mechanical employments: they are all traffickers in one way or other, the most respectable being merchants, the inferior class brokers and jobbers. Of the Roman Catholic church the heads are two archbishops and six bishops; among the Protestants the highest authority is the general consistory of Munich.

Education.

Bavaria was formerly as backward in regard to education as Austria, or any part of the south of Germany; but in the course of the last and present age considerable efforts have been made to lessen the prevailing ignorance. At Munich there are scientific and literary academies, as well as a university, a lyceum, a gymnasium, and other public schools. The university has a very numerous attendance of students, being 1406 in 1846; and there are two provincial universities on a small scale, one Catholic at Wurzburg, the other Protestant at Erlangen in Franconia. In the kingdom at large there are nine lyceums, twenty-six gymnasia, about sixty progymnasia, besides nine normal, twenty-six trade, three polytechnic, and about 5400 common schools, at which it is computed that about half a million of children or young people of both sexes receive instruction in reading and writing. These certainly form a great contrast to the indifference and neglect of former times; and the government continues to evince much solicitude for the diffusion of instruction. Trade schools here, as in other parts of Germany, have been established for the purpose of affording to mechanics more suitable education than they could otherwise obtain, including mathematics, mechanics, drawing, chemistry, architecture, &c. These schools are supported by the commune, aided when necessary by the province; and commissioners are annually sent by government to examine and report upon them to the minister of trade. The course extends over three years, from the age of twelve to fifteen; after which pupils may enter one of the three polytechnic schools, where a still higher course of instruction is imparted, also extending over three years; but engineers have a special fourth year's course. A building school was established at Munich in 1823, and is chiefly intended for carpenters and masons, who are there instructed in architecture, drawing, geometry, stone-cutting, modelling ornaments, &c.

Bavaria.

The national character of the Bavarians resembles that of the Austrians; being generally marked by fidelity and loyalty. In matters of religion they are credulous, and even superstitious. In short, the will of their superiors is received by the lower orders implicitly as a law in political as in ecclesiastical affairs. A great deal was said fifty years ago about the masonic and other secret societies said to have been formed in this country at the time of the French revolution, and to have aimed at combining their efforts with similar societies in Prussia for the overthrow of the established governments. Such assertions, if not absolutely false, must have rested on a very slender foundation, no people being less inclined than the Bavarians to join in revolutionary projects, or less capable of conceiving that any advantage could possibly result from them.

Govern-ment.

The government of Bavaria in the early ages of the German empire did not descend from father to son: it involved an important military trust, and was conferred by the emperor on princes of different families until the thirteenth century. Towards the close of that century Louis, of the house of Wittelsbach, Duke of Lower Bavaria and Count Palatine of the Rhine, left two sons, Rodolph and Louis, between whom, according to the usage of the age, the father's dominions were shared, the elder receiving the palatinate of the Rhine, the latter the duchy of Bavaria. Small as the Rhenish palatinate was, its comparative civilization made it the more valuable of the two; and its head had the important privileges of an elector of the empire. From the two princes just mentioned descended the rulers of these respective states during five centuries and more; until, in 1778, on the failure of the Bavarian line, Charles Theodore, Count of the Palatinate, obtained the succession, and removed to Munich, since which time the two countries have been governed as one state. Charles Theodore ruled Bavaria above twenty years. He evinced much anxiety for the improvement of his new subjects, but, like his contemporary the Emperor Joseph II. of Austria, he made no sufficient allowance for their deficiency of culture, and their unfitness to comprehend the advantage of many of his proposed changes. He died in 1799, and was succeeded by Maximilian I., a prince of equal philanthropy and greater prudence, who governed Bavaria twenty-six years. He was succeeded in 1825 by his son Louis, who specially distinguished himself by his zeal for the promotion of the fine arts. Finding himself unequal to the emergency of the times, he abdicated in March 1848, in favour of his son Maximilian II., the present king.

Bavaria, like other German states, has long had its states or parliament, composed of nobility and prelates. Its present form of government is founded partly on long-established usage, partly on a constitutional act of great length, passed in May 1818. The country is there declared an integral part of the Germanic confederation, and the monarchy hereditary, with a legislative body of two houses, the upper and lower. The title of the sovereign is simply king of Bavaria; that of his presumptive heir is crown prince of Bavaria. The executive power is vested altogether in the king, whose person is declared inviolable: the responsibility rests with the ministers, whose functions are nearly the same as those of ministers in England or France; and they have respectively offices for foreign affairs, for the home department, for the treasury, the army, and the administration of justice. The upper house of the Bavarian parliament comprises the princes of the blood-royal, the two arch-

Bavaria ‖ Baxter.

bishops, the barons or heads of families of landed property, the president of the Protestant consistory, and any other members whom the king may nominate, either as hereditary peers or as counsellors for life; but the latter must not exceed a third of the hereditary members. The lower house consists of about 140 deputies, of whom an eighth part must be of the class of nobility, another eighth of the clergy, a fourth part citizens or burghers, and the remaining half landed proprietors. Each of the three universities also names a representative. A general election takes place once in six years, and the number of members bids fair to increase; for the elective law prescribes that there shall be a deputy or member of the lower house for every 7000 families in the kingdom. The king generally convenes the parliament once a year; and by the constitution it is obligatory on him to do so at least once in three years. The direct taxes must be granted anew under the authority of the parliament once in six years.

The adoption of this constitution was accompanied by the abolition of all that remained of personal servitude among the peasantry; for many Bavarians of the lower class were until lately serfs, being paid for their labour not by wages, but by maintenance; and they were consequently very indolent. The political improvements still wanting in Bavaria are a more complete equalization of taxes; publicity in the proceedings of courts of justice; a removal of the restrictions on trade with the neighbouring states; and an amendment of the penal code. The liberty of the press is already complete.

Foreign politics.

No part of Europe, if we except the Netherlands, has been more exposed to invasion than Bavaria, and in none has the painful interest arising from military conflicts been given to a greater variety of places. Two centuries ago, both Bavaria and Franconia were laid waste in the Thirty Years' War between the Catholics and Protestants. It was near Augsburg, on the banks of the Lech, that Gustavus Adolphus obtained, in 1632, a memorable victory over the Austrians and other Catholic allies, commanded by Count Tilly. At Nuremberg the success of the Swedish sovereign was for a time arrested by the talents of Wallenstein; but at Nordlingen, two years after, the death of the king and the injuries of the Protestants were avenged in a dreadful conflict. The French next took part in the war, and carried devastation throughout this part of Germany. In the succeeding age Bavaria was invaded by our countrymen and their allies; and it was at Schellenberg, a strong position near the Danube, that the Duke of Marlborough first worsted the Bavarians, in July 1704, above a month previous to the battle of Blenheim. In the wars of the French revolution both Franconia and Bavaria were repeatedly overrun. It was at Amberg that the Archduke Charles stopped the advance of the French in 1796, and at Wurzburg that he finally defeated them; successes repeated with equal effect three years after, when, in March 1799, he again met their army on Bavarian ground, near the banks of the Lech. The subsequent operations in this country were equally pernicious to it, though very different in their political results. The name of Hohenlinden recals the triumph of Moreau in 1800; that of Ulm the surrender of the Austrian army under Mack, in October 1805. Lastly, it was at Eckmuhl and Ratisbon, in 1809, that Buonaparte obtained over the Austrians victories which compelled them to retreat with heavy loss, and opened to him the gates of Vienna. (J. L—E.)

Bavaria ‖ Baxter.

BAVIUS and MÆVIUS, two despicable poets whose enmity to Virgil and Horace has immortalized their names. *Qui Bavium non odit amet tua carmina, Mævi.* (Virg. *Ecl.* iii. 90. See also Horace, *Epod.* x.)

BAWTRY, a market-town in the parish of Blythe, in the west riding of Yorkshire. It is a small but well-built town, and stands on a gentle eminence, sloping towards the river Idle, which empties itself into the Trent, and by which some trade is carried on. It is 153 miles from London, on the great road to Scotland, and has a good market on Thursday. Pop. in 1851, 1170.

BAXTER, ANDREW, a very ingenious metaphysical writer, the son of a merchant in Old Aberdeen, was born in 1686 or 1687, and educated in King's College there. His principal employment was that of private tutor to young gentlemen; and among his pupils were Lord Gray, Lord Blantyre, and Mr Hay of Drummelzier. About 1724 he married the daughter of a clergyman in Berwickshire. A few years afterwards, he published, in quarto, but without date, *An Inquiry into the Nature of the Human Soul*, wherein its immateriality is evinced from the principles of reason and philosophy. In 1741 he went abroad with Mr Hay, and resided several years at Utrecht, having Lord Blantyre also under his care. From this place he made excursions into Flanders, France, and Germany, his wife and family residing in the mean time chiefly at Berwick-upon-Tweed. He returned to Scotland in 1747, and resided till his death at Whittingham, in the county of East Lothian. He drew up, for the use of his pupils and his son, a piece entitled *Matho, sive Cosmotheoria puerilis, Dialogus, in quo prima elementa de mundi ordine et ornatu proponuntur*, &c. This was afterwards greatly enlarged, and published in English in two volumes 8vo. In 1750 was published an appendix to his *Inquiry into the Nature of the Human Soul*, in which he endeavours to remove some difficulties which had been started against his notions of the *vis inertiæ* of matter, by Maclaurin, in his *Account of Sir Isaac Newton's Philosophical Discoveries*. To this piece Mr Baxter prefixed a dedication to Mr John Wilkes, with whom he had commenced an acquaintance abroad. He died on the 23d April 1750, after suffering for some months under a complication of severe disorders, of which the gout was the chief.

Baxter's learning and abilities are sufficiently manifested in his writings. He was also greatly esteemed for the benevolence and candour of his disposition, and had numerous friends and correspondents of eminence, among whom was Dr Warburton, bishop of Gloucester. He left many manuscripts behind him, and intended, had he lived, to complete his work upon the human soul. A second edition of it was published in two volumes 8vo in 1737, and a third in 1745.

BAXTER, *Richard*, an eminent Nonconformist divine, was born in the village of Rowton in Shropshire, on the 12th November 1615. His father's example fostered the principles of serious piety in his youthful mind. After receiving a competent education he was sent to London, under the patronage of Sir Henry Herbert, master of the revels; but he soon returned into the country to study divinity, and in 1638 received ordination in the Church of England; but as he conscientiously refused to subscribe to the oath of universal obedience to the doctrines of the church, he left the establishment.

When the civil war broke out he sided with the parliament, and after the battle of Naseby acted as chaplain in Colonel Whalley's regiment. Although serving under the parliament he professed himself friendly to the Church of England. In consequence of ill health he retired from his military chaplaincy in 1647. Upon the opening of the Long Parliament he was chosen vicar of Kidderminster. But in the heat of the civil wars he removed from that town to

Baxter. Coventry, and preached to the garrison and inhabitants. When Oliver Cromwell was made Protector, he once preached before him, but he declined complying with his measures, and even once told him in a conference that the people of England deemed the ancient monarchy a blessing.

He came to London just before the deposition of Richard Cromwell, and preached before the parliament the day previous to that on which they voted the return of Charles II. The king, on his restoration, appointed Baxter one of his chaplains in ordinary; and he assisted at the conference in the Savoy as one of the commissioners for settling the fundamentals in religion, and reforming the liturgy. He was offered the bishopric of Hereford, which he refused, desiring no higher preferment than the liberty of continuing minister of Kidderminster. This, however, was denied him, for he was not permitted to preach there above twice or thrice after the Restoration. He accordingly returned to London and preached occasionally in or about the city till the Act of Uniformity passed. In 1662 he married Margaret Charleton, daughter of Francis Charleton, Esq., of the county of Salop. This lady was a woman of great piety, entered thoroughly into her husband's views concerning religion, and cheerfully shared all his sufferings both in and out of prison. During the plague in 1665 Baxter retired into Buckinghamshire; but afterwards returned to Acton, where he staid till the act against conventicles expired, when his audience became so large that he wanted room. After this he was committed to prison; but having procured a *habeas corpus*, he was discharged. After the indulgence in 1672, he returned to London; but in 1682 he was seized for coming within five miles of a corporation. In 1684 he was again seized; and in the reign of James II., in 1685, he was committed prisoner to the King's Bench, and tried before the infamous Judge Jeffreys for his *Paraphrase on the New Testament*, which was called a "scandalous" and "seditious" book against the government. Mr Macaulay (*History of England*, vol. i. p. 487) gives the following graphic sketch of the character and trial of Baxter:—

"About the same time a culprit, who bore very little resemblance to Oates or Dangerfield, appeared on the floor of the court of King's Bench. No eminent chief of a party has ever passed through many years of civil and religious dissension with more innocence than Richard Baxter. He belonged to the mildest and most temperate section of the Puritan body. He was a young man when the civil war broke out. He thought that the right was on the side of the houses; and he had no scruple about acting as chaplain to a regiment in the parliamentary army: but his clear and somewhat sceptical understanding, and his strong sense of justice, preserved him from all excesses. He exerted himself to check the fanatical violence of the soldiery. He condemned the proceedings of the High Court of Justice. In the days of the commonwealth he had the boldness to express, on many occasions, and once even in Cromwell's presence, love and reverence for the ancient institutions of the country. While the royal family was in exile, Baxter's life was chiefly passed at Kidderminster in the assiduous discharge of parochial duties. He heartily concurred in the Restoration, and was sincerely desirous to bring about a union between Episcopalians and Presbyterians. For, with a liberality rare in his time, he considered questions of ecclesiastical polity as of small account when compared with the great principles of Christianity, and had never, even when prelacy was most odious to the ruling powers, joined in the outcry against bishops.

"The attempt to reconcile the contending factions failed. Baxter cast in his lot with his proscribed friends, refused the mitre of Hereford, quitted the parsonage of Kidderminster, and gave himself up almost wholly to study. His theological writings, though too moderate to be pleasing to the bigots of any party, had an immense reputation. Zealous churchmen called him a Roundhead; and many Nonconformists accused him of Erastianism and Arminianism. But the integrity of his heart, the purity of his life, the vigour of his faculties, and the extent of his attainments, were acknowledged by the best and wisest men of every persuasion. His political opinions, in spite of the oppression which he and his brethren had suffered, were moderate. He was friendly to that small party which was hated by both whigs and tories. He could not, he said, join in cursing the Trimmers, when he remembered who it was that had blessed the peacemakers. Baxter.

"In a commentary on the New Testament he had complained, with some bitterness, of the persecution which the dissenters suffered. That men who, for not using the prayer-book, had been driven from their homes, stripped of their property, and locked up in dungeons, should dare to utter a murmur, was then thought a high crime against the state and the church. Roger Lestrange, the champion of the government, and the oracle of the clergy, sounded the note of war in the *Observator*. An information was filed. Baxter begged that he might be allowed some time to prepare for his defence. It was on the day on which Oates was pilloried in Palace Yard that the illustrious chief of the Puritans, oppressed by age and infirmities, came to Westminster Hall to make this request. Jeffreys burst into a storm of rage, 'Not a minute,' he cried, 'to save his life. I can deal with saints as well as with sinners. There stands Oates on one side of the pillory; and if Baxter stood on the other, the two greatest rogues in the kingdom would stand together.'

"When the trial came on at Guildhall, a crowd of those who loved and honoured Baxter filled the court. At his side stood Doctor William Bates, one of the most eminent of the Nonconformist divines. Two whig barristers of great note, Pollexfen and Wallop, appeared for the defendant. Pollexfen had scarce begun his address to the jury, when the chief justice broke forth: 'Pollexfen, I know you well. I will set a mark on you. You are the patron of the faction. This is an old rogue, a schismatical knave, a hypocritical villain. He hates the liturgy. He would have nothing but longwinded cant without book:' and then his lordship turned up his eyes, clasped his hands, and began to sing through his nose, in imitation of what he supposed to be Baxter's style of praying, 'Lord, we are thy people, thy peculiar people, thy dear people.' Pollexfen gently reminded the court that His late Majesty had thought Baxter deserving of a bishopric. 'And what ailed the old blockhead then,' cried Jeffreys, 'that he did not take it?' His fury now rose almost to madness. He called Baxter a dog, and swore that it would be no more than justice to whip such a villain through the whole city. Wallop interposed, but fared no better than his leader. 'You are in all these dirty causes, Mr Wallop,' said the judge. 'Gentlemen of the long robe ought to be ashamed to assist such factious knaves.' The advocate made another attempt to obtain a hearing, but to no purpose. 'If you do not know your duty,' said Jeffreys, 'I will teach it you.' Wallop sat down; and Baxter himself attempted to put in a word. But the chief justice drowned all expostulation in a torrent of ribaldry and invective, mingled with scraps of Hudibras. 'My Lord,' said the old man, 'I have been much blamed by dissenters for speaking respectfully of bishops.' 'Baxter for bishops!' cried the judge, 'that's a merry conceit indeed. I know what you mean by bishops—rascals like yourself, Kidderminster bishops, factious snivelling Presbyterians!' Again Baxter essayed to speak, and again Jeffreys bellowed, 'Richard! Richard! dost thou think we will let thee poison the court? Richard! thou art an old knave. Thou hast written books enough to load a cart, and every book as full of sedition as an egg is full of meat. By the grace of God, I'll look after thee. I see a great many of your brotherhood waiting to know what

Baxter ‖ Bay Salt.

will befall their mighty Don. And there,' he continued, fixing his savage eyes on Bates, 'there is a doctor of the party at your elbow. But, by the grace of God Almighty, I will crush you all.' Baxter held his peace. But one of the junior counsel for the defence made a last effort, and undertook to show that the words of which complaint was made would not bear the construction put on them by the information. With this view he began to read the context. In a moment he was roared down; 'You shan't turn the court into a conventicle.' The noise of weeping was heard from some of those who surrounded Baxter. 'Snivelling calves!' said the judge. Witnesses to character were in attendance, and among them were several clergymen of the Established Church. But the chief justice would hear nothing. 'Does your lordship think,' said Baxter, 'that any jury will convict a man on such a trial as this?' 'I warrant you, Mr Baxter,' said Jeffreys; 'don't trouble yourself about that.' Jeffreys was right. The sheriffs were the tools of the government. The juries, selected by the sheriffs from among the fiercest zealots of the tory party, conferred for a moment, and returned a verdict of Guilty. 'My lord,' said Baxter, as he left the court, 'there was once a chief justice who would have treated me very differently.' He alluded to his learned and virtuous friend Sir Matthew Hale. 'There is not an honest man in England,' answered Jeffreys, 'but looks on thee as a knave.'

"The sentence was, for those times, a lenient one. What passed in conference among the judges cannot be certainly known. It was believed among the Nonconformists, and is highly probable, that the chief justice was overruled by his three brethren. He proposed, it is said, that Baxter should be whipped through London at the cart's tail. The majority thought that an eminent divine, who, a quarter of a century before, had been offered a mitre, and who was now in his seventieth year, would be sufficiently punished for a few sharp words by fine and imprisonment."

Baxter continued in prison two years; but was at last discharged, and had his fine remitted by the king. He died on the 8th of December 1691, and was buried in Christ Church. His works consisted of 112 separate publications, which were collected and published in four volumes folio in 1707.

BAXTER, *William*, nephew and heir to the preceding, was an eminent schoolmaster and critic. He was born at Llanlugan in Montgomeryshire, in the year 1650. At the age of eighteen, when he first went to school, he knew not one letter, nor understood one word of any language but Welsh; but he improved his time so well that he became a person of great and extensive knowledge. The natural bent of his mind led him chiefly to the study of antiquities and philology, in which he composed several books. The first he published was a grammar, in 1679, entitled *De Analogia seu Arte Latinæ Linguæ Commentariolus.* He also published a new and correct edition of Anacreon, with notes; an edition of Horace; a dictionary of British antiquities, in Latin; and several other works. He was a great master of the ancient British and Irish tongues, and particularly skilled in the Latin, Greek, northern, and oriental languages. He died on the 31st May 1723, after being above twenty years master of Mercer's school in London.

BAY (Saxon, *byge*, an angle), an arm of the sea extending into the land. It is smaller than a gulf, and larger than a creek.

BAY, the *Laurus nobilis*, a tree belonging to the natural order *Lauraceæ*. See BOTANY.

BAY *Colour* denotes a sort of reddish-brown, of various shades, approaching to chestnut. Bay horses (to which the term is chiefly applied) are characterized by the black mane and tail.

BAY *Salt* is salt made by the action of the sun and air on sea-water, or on any water containing salt, in contradistinction to that which is manufactured by artificial evaporation.

Bay Window ‖ Bayard.

BAY *Window*, a projecting window rising from the ground or basement, either in the form of a semicircle or otherwise, forming a space similar in shape to a bay: hence its name.

BAYADEER, the Indian term for a dancing girl, supposed to be a corruption of the Portuguese *bailadeira*, a female dancer. See DANCING GIRLS.

BAYAN-KHARA, a range of mountains in Eastern Asia, which the Chinese represent as occupying the centre of the great high plateau of that quarter of the world, about Lat. 36. N. and Long. 100 E. (Ritter's *Asia.*)

BAYARD, PIERRE DU TERRAIL, CHEVALIER DE, one of the most illustrious heroes of the chivalrous age, or rather one of the latest representatives of the ancient chivalry, was descended from an ancient and noble family in Dauphiné, and was born in 1476 at the château of Bayard, near Grenoble. He was esteemed by his contemporaries the model of soldiers and men of honour, and denominated "the knight without fear and without reproach." He accompanied Charles VIII. in his expedition to Italy, and gave remarkable proofs of his valour, especially at the battle of Fuornuovo. He was dangerously wounded at the storming of Brescia, and was nursed in the house of a lady, who on his recovery presented him with two thousand pistoles for the protection he had afforded her family against the soldiers. With knightly courtesy he accepted the gift, and bestowed it on her two daughters for their marriage portions; an action which has been celebrated by many historians. On his return to France he was made lieutenant-general of Dauphiné. He fought by the side of Francis I. in the tremendous battle of Marignano; and that young prince afterwards insisted on being knighted by his hand, after the manner of the ancient knights. During six weeks he defended the town of Mezieres against the army of Charles the Fifth. In 1524, at the retreat of Rebec, the conduct of the rear was committed to the Chevalier Bayard; who, though so much a stranger to the arts of a court that he never rose to the chief command, was always called, in times of real danger, to the posts of greatest difficulty and importance. He put himself at the head of the men-at-arms; and animating them by his presence and example to sustain the shock of the enemy's whole troops, he enabled the rest of his countrymen to make good their retreat. But in this service he received a mortal wound; and being unable to continue longer on horseback, he ordered one of his attendants to place him against a tree, with his face to the enemy; then fixing his eyes on the guard of his sword, which he held up instead of a cross, he addressed his prayers to God, and, in this attitude, which became his character both as a soldier and as a Christian, he calmly awaited the approach of death. Bourbon, who led the foremost of the enemy's troops, found him in this situation, and expressed pity and regret at the sight. "Pity not me," cried the high-spirited chevalier; "I die as a man of honour ought, in the discharge of my duty. They indeed are objects of pity who fight against their king, their country, and their oath." The Marquis de Pescara, coming up soon after, manifested his admiration of Bayard's virtue as well as sorrow for his fate, with the generosity of a gallant enemy; and finding that he could not be removed with safety from the spot, he ordered a tent to be pitched there, and appointed proper persons to attend him. Bayard died, as his ancestors for several generations had done, on the field of battle. His death took place on the 30th of April 1524, at the age of forty-eight. Pescara ordered the body to be embalmed; and the Duke of Savoy commanded it to be received with royal honours in all the cities of his dominions. In Dauphiné, Bayard's native province, the people of all ranks came out in a solemn procession to meet it. The life of Bayard was written by one of his secretaries, and has since appeared under various forms.

Bayazid ‖ Bayeux.

BAYAZID, or BAJAZID, a city of Turkish Armenia, in the pashalic of Erzeroum, situated on a mountain, the summit of which is strongly fortified. It is surrounded by a wall and ramparts; and contains two churches, three mosques, and a monastery, that of Karu Killeesea, which is famous for the beauty of its architecture, as well as for its antiquity and grandeur. This city, which, when visited by Kinneir, had about 30,000 inhabitants, is now in a ruinous and filthy condition. According to the accounts given by Messrs Smith and Dwight, the American missionaries who visited it in 1832, the population must be considerably under 5000. Great numbers of the Armenian inhabitants have emigrated to the Russian territories. It is 50 miles S.S.W. of Erivan, and 140 east of Erzeroum. Long. 43. 26. E. Lat. 39. 24. N.

BAYEN, PIERRE, a celebrated chemist, and member of the Institute of France, was born in 1725, at Chalons-sur-Marne. Showing a great inclination for study, he was sent by his parents to school at Troyes, where he went through a course of classical education with success.

The bent of his disposition was to physical science. He went to Paris in 1749, and became the pupil and friend of an eminent druggist. In this situation he acquired a complete knowlege of the profession; and, before the age of thirty, he was appointed chief apothecary to the French army in Germany, in the Seven Years' War, a situation which he filled with industry, intelligence, and integrity. After the conclusion of peace, he returned to Paris, and was employed for several years by the government in making analyses of the mineral waters of France.

On his return to Paris, he made analyses of different minerals collected chiefly during his residence in the Alpine region of the Pyrenees. Amongst these is the marble of Campan, of which there are two varieties, the red and the green. They are brought from that country to Paris, where they are used with striking effect in ornamental architecture; as may be seen in the columns of the Great Trianon at Versailles, in the interior of the church of St Sulpice, and in other great buildings. These analyses are published in the *Mémoires présentés à l'Académie par divers Savans*, commonly called *Memoires des Savans Etrangers*.

Bayen made most accurate experiments on the oxides of mercury, to show that oxidation arises from the absorption of a portion of the atmospheric air, and that the existence of the phlogiston of Stahl could not be proved. Lavoisier, who was present when the account of these experiments was read, was employed at that time in examining the metallic oxides; and soon after brought the subject into a clearer light, demonstrating the nature of oxygen, and the composition of the atmosphere.

Bayen enjoyed good health till sixty, and died at the age of seventy-six, in the year 1801. He was a man of sound judgment, of strict integrity, and acquainted with several other branches of knowledge besides that which he particularly cultivated. There is a collection of his works, entitled *Opuscules Chimiques*, 1798, 2 vols. 8vo. (W. A. C.)

BAYEUX, the capital of an arrondissement of the same name in the department of Calvados, France. It is situated in a fruitful valley on the river Aure, 17 miles W.N.W. of Caen. The principal building is the cathedral, a majestic edifice of great antiquity, in which is the celebrated tapestry, said to have been the work of Matilda, queen of William the Conqueror, and representing the events connected with the Norman conquest. It is now believed to be an authentic monument of that era; and has been engraved by the Society of English Antiquaries in the 6th volume of *Monumenta Vetusta*. Bayeux is the seat of a bishopric, and has tribunals of primary jurisdiction and commerce, a communal college, and a public library. Its manufactures are linen and cotton goods, hosiery, lace, &c. Pop. (1851) 8835. The arrondissement has 6 cantons, 144 communes, and 79,976 inhabitants

Bayla ‖ Bayle.

BAYLA, or BELA, a town of Beluchistan, capital of the province of Lus, on the north-eastern bank of the river Poorally. About one-third of the town in the western quarter is encompassed by a mud wall. The streets are narrow; but from the elevated situation of the town, and its rocky site, they are always clean, even in the wettest weather. The bazaar is very neat. Bayla is the residence of the chief of Lus, whose government is mild and equitable, and insures complete protection to mercantile dealers. His durbar or hall of audience is a large open apartment of very ordinary structure, and he maintains little or no state. Pop. 5000. Distance north of Khelat, 293 miles. Long. 66. 40. E. Lat. 26. 10. N.

BAYLE, PIERRE, author of the *Historical and Critical Dictionary*, was born on the 18th November 1647, at Carlat, a village in the county of Foix, in France. His father, Jean Bayle, a Calvinist minister, took upon himself the early education of his son, and instructed him in Latin and Greek. The young Bayle was afterwards sent to Puylaurens, where he continued his studies with equal ardour and success. He completed his rhetorical studies in this academy, and went in 1669 to Toulouse, to study philosophy under the Jesuits. There, embarrassed by some objections raised against his religious belief, he abjured Calvinism for Catholicism, which for a short time appeared to him the more rational system: but renewed reflection and more thorough investigation soon brought him back to his former faith. Immediately on his restoration to the reformed church, he went to Geneva, and adopted the principles of Cartesianism in preference to the Peripatetic scholasticism which he had learnt from the Jesuits; and there also he formed lasting friendships with the celebrated professors of theology, Pictet and Leger, and especially with a young man named Basnage, who afterwards distinguished himself as an author and minister of the gospel. In the year 1675, a chair of philosophy was vacant at the Sedan academy. Pressed by Basnage, who had then finished his theological studies in this town, and who had obtained for his friend the help of Jurieu his master, Bayle competed for the place and obtained it. He occupied this post for six years, to the satisfaction of all, and even of Jurieu himself, who, in spite of his envious character, could not withhold from him his esteem. In 1681, five years before the revocation of the edict of Nantes, the Calvinist university of Sedan was broken up, and Bayle went with Jurieu to Rotterdam, where M. de Paets founded for them *l'Ecole illustre*. The public teaching with which Bayle was there intrusted comprehended philosophy and history. His lectures, and particularly his numerous publications, soon attracted general attention; all the savants of Europe corresponded with him, and the learned Queen Christina of Sweden wrote to him with her own hand. But he did not long enjoy this celebrity undisturbed. His colleague Jurieu persecuted him with cruel animosity. He denounced him as an atheist to the consistory, and as a conspirator to the public authorities. His intrigues, after having for a long time proved futile, at length succeeded. In 1693 the magistrates of Rotterdam removed Bayle from his office, and forbade him to give private instructions. His misfortune appears to have affected him but little; he rather congratulated himself at having escaped from the cabals and parties so common in the academies. In spite of the persecutions which disturbed his latter years, he was so happy in the enjoyment of independence, that when, in 1706, the Count of Albemarle asked him as a favour to come and live in his house at the Hague, Bayle refused.

But he was now suffering from the malady which at last proved fatal to him. An affection of the chest, for which he refused to seek any remedies, as he considered it incurable, made rapid progress, which he observed with perfect calmness. His activity was never for a moment inter-

Bayle.

rupted; his labours proceeded as perseveringly as when he was in perfect health, till death overtook him, pen in hand, on the 28th December 1706, in the fifty-ninth year of his age.

The lives of few literary men have been so completely occupied as that of Bayle. From his twentieth year he scarcely allowed himself a moment's repose. To those who were astonished at the rapidity with which his publications succeeded each other, he answers, in the preface to the second volume of his dictionary, "Diversions, parties of pleasure, games, collections, country excursions, visits, and such other recreations as are said by many men of letters to be necessary, have no charms for me; I lose no time. I do not even spend any in domestic cares, or in endeavouring to attain anything whatever, nor in solicitations, nor in any other affairs. In this way an author accomplishes much in few years."

He wrote with extreme facility, and rarely revised his first copy. "I never (says he) make a rough draft of an article; I commence and finish it without stopping." What he chiefly sought in the expressions in which he clothed his thoughts was clearness, and his style is rather lively and flowing, than elegant and chaste.

His erudition was immense, and at once exact and profound. His logic was equal to his learning, for he was one of those rare geniuses with whom retentiveness of memory does not weaken the reasoning powers. Unfortunately these extraordinary talents were often wasted on profitless paradox and bewildering scepticism. The subtility of his reasoning faculties led him to doubt the most universally acknowledged facts. All the important questions which philosophy proposes to solve entangle themselves, according to Bayle, in inextricable difficulties. The proposition that *there is one God* does not, according to him, possess indisputable evidence. Nature is an impenetrable deep. "Man," he says, "is the stumbling-block of the true and the false, and nothing is so difficult for reason alone to penetrate, as what we call a rational animal. What do we know of the nature and destiny of souls? arguments have been equally advanced for their materiality and immateriality, for their mortality and immortality. The principles on which morality rests are still less certain than those which give to the physical sciences their tottering base and their uncertain foundation." He gives a true character of himself when he says (Lettre au P. Taurnemene), "I am only Jupiter, the cloud-compeller; my talent is to form doubts, but they are to me only doubts." His scepticism enveloped every thing. He does not attack openly and directly the dogmas which he impugns; his method is to oppose to the system which supports certain doctrines some other system, ancient or modern, which denies them, and thus to break the contradictory doctrines against each other, leaving the truth buried under their ruins.

The great work of Bayle is the *Dictionnaire Historique et Critique*, which, with much that is of little interest or value, contains a large number of articles remarkable for erudition and critical discernment, and has exercised no inconsiderable influence on the literature and philosophy of Europe. The first edition was published in 1699 in 2 vols. fol. Of the twelve subsequent editions, the best are, that of Des Maizeaux (with life of Bayle), Basle and Amst. 1740, 4 tom. fol.; and that of Beuchot, Paris, 1820, &c., 16 tom. 8vo. The latter is enriched with the critical remarks of various authors. The English translation by Birch and Lockman, Lond. 10 vols. fol. 1734–41, contains considerable additions to the original. The *Œuvres Diverses* of Bayle were published in 1727–31, 4 tom. fol. at the Hague; and his *Lettres Choisies* at Rotterd. 1714, and Amst. 1729, 3 tom. 12mo.

(See Durevert, *Histoire de Bayle*, &c., Amst. 1716; G. F. Schœtterbeck, *Diss. de P. Baylio*, Tubing. 1719, 4to; Feuerbach, *Pierre Bayle*, &c., Ansp. 1838, 8vo; Damiron, in the *Mem. de l'Acad. des Sciences Mor. et Polit.*, tom. xi. p. 319; Tennemann, *Geschichte der Philos.*; St Beuve, in the *Rev. des Deux Mondes*, Dec. 1835.)

Bayly (Bazaar.

BAYLY, Lewis, an English prelate, author of a well-known book entitled *The Practice of Piety*. He was born at Caermarthen in Wales, educated at Oxford, appointed minister of Evesham about 1611, made chaplain to King James, and promoted to the see of Bangor in 1616. He died in 1632.

BAYONET, from the French *baïonette*, and so called, it is said, because this weapon was first made at Bayonne. It is a kind of three-sided dagger-like weapon, which was originally screwed into the muzzle of the gun; and thus it could only be used after the piece was discharged. The bayonet is now made with a hollow iron handle, which embraces the muzzle exteriorly, so that the soldier fires with his bayonet fixed. The original invention as well as the subsequent improvement of this weapon is due to the French, who were also the first to employ it, and, according to Folard, gained important advantages in consequence, before the use of it became general. Its great advantage consists in rendering the musket a pike, and thus providing the soldier with a weapon which he can at all times employ, either to resist an attack of cavalry, or to charge the enemy's infantry. See Guibert, *Essai Général de Tactique*. This weapon was formerly called dagger; and in some old English authors it is written *bagonet*.

BAYONNE, the ancient *Lapurdum*, a first-class fortified city of France, in the department of Lower Pyrenees, and capital of an arrondissement of the same name. It is well built, and agreeably situated at the confluence of the Nive and Adour, about three miles from the sea. A bar at the mouth of the river prevents large vessels from entering except at high water, when at spring tides there is a depth of from 13 to 15 feet, and from 9 to 11 feet at neaps. The citadel is one of the finest works of Vauban, and the cathedral is a small but elegant Gothic structure of the thirteenth century. Bayonne is the seat of a bishopric, and has courts of primary jurisdiction and commerce, an exchange, a mint, theatre, naval and commercial docks, schools of commerce and navigation, &c.; with distilleries, sugar refineries, glass works, &c. Its export trade is considerable, particularly in chocolate, liqueurs, cream of tartar, and hams. The Nive and Adour divide the town into three nearly equal parts, communicating with each other by bridges. The Bayonne, which lies on the left bank of the Nive, contains the old castle; Little Bayonne, where the new castle stands, is situated between the Nive and the Adour; and the suburb Saint Esprit occupies the right bank of the Adour. The last is not comprehended in the commune of Bayonne, but forms a separate commune in the department of Landes. The bayonet derives its name from this place, where it is said to have been invented. Bayonne, though often besieged, has never been taken, and is one of the few places that refused to participate in the massacre of St Bartholomew. Pop. of commune in 1851, 16,299. The arrondissement of the same name contains 8 cantons, 53 communes, and (in 1851) 88,185 inhabitants.

BAZA, a city of Granada, in the Sierra Nevada, with a population of 10,133, a cathedral, and a seminary for the education of priests. It stands in a fruitful valley. Lat. 37. 30. N. Long. 2. 50. W.

BAZAAR, or Bazar, a denomination among the Turks and Persians, given to a kind of exchange, or place where stuffs and other wares are sold. The word *bazaar* is of Persic origin, and literally denotes sale or exchange of goods. Some of the Eastern bazaars are open, like the market-places in Europe, and serve the same purposes, more particularly for the sale of the bulky and less valuable commodities. Others, again, are covered with lofty ceilings, or domes, pierced to

give light; and it is in these that the jewellers, goldsmiths, and other dealers in the richer wares, have their shops. The bazaar or maidan of Ispahan is one of the finest places in Persia, and greatly surpasses all the exchanges in Europe. The bazaar of Tauris was famed for its extent, having several times contained 30,000 men ranged in order of battle; and the bazaar of Ali Pacha at Adrianople is of very large dimensions. At Constantinople there are the old and the new bazaar, which are large square buildings, covered with domes, and sustained by arches and pilasters. The name of bazaar has lately been given to various establishments in London and other cities, where all sorts of goods and wares are exhibited for sale.

BAZAS, an arrondissement in the department of the Gironde, in France, extending over 604 square miles, and comprehending 7 cantons and 68 communes, with a population of 55,112 persons. The chief place is a market-town of the same name, which in 1851 contained 4437 inhabitants, employed in various kinds of manufactures, particularly glass. Long. 0. 12. 25. W. Lat. 44. 25. 55. N.

BAZAT, or BAZA, in *Commerce*, a long, fine-spun cotton, which is brought from Jerusalem, whence it is called *Jerusalem cotton.*

BAZEEGURS, a tribe of Indians, inhabiting different parts of the peninsula of Hindustan. They are recognised by several appellations, as Bazeegurs, Panchperee, Kunjura, or Nuts; they follow a mode of life distinguishing them from the Hindus, among whom they dwell; and abstain from intermixing their families with the Hindus, and from any intercourse by which they can be united. They are dispersed throughout the whole of India, partly in wandering tribes, partly adhering to fixed residences, but the greater proportion lead a nomadic life.

The Bazeegurs are divided into seven castes; but besides those who are united into sets or castes, there are individuals who wander about endeavouring to pick up a precarious livelihood. Although the Bazeegurs are distinguished by their manners and customs from the natives of Hindustan, their features do not certainly discriminate them as a separate race. Some of their women are reputed very beautiful, and are thence sought after in those temporary alliances common in the East. The Bazeegurs, more especially distinguished by that name, are the most civilized of the whole; they are Mahometans in food, apparel, and religion. The Panchperee profess no system of faith in preference, adopting indifferently that of any village, whither their wanderings may guide them. Some traverse the country as Mahometan Fakeers, and live on the ill-directed bounty of devotees; and a particular association among them, of bad repute or abject superstition, has been accused of sacrificing human victims.

The chief occupation of the Bazeegurs seems to consist in feats of address and agility to amuse the public, in which both males and females are equally skilful. The former are extremely athletic, and the women are taught dancing, which, instead of the graceful motions seen in the north, consists principally of a display of lascivious gestures. Most, if not all the men, are jugglers, tumblers, and actors, in which they are very adroit. The people of each sect, or *dramatis personæ*, are hired out by a sirdar or manager of a company, for a definite period, generally one year, after which they are at liberty to join any other party. Both males and females pursue such a systematic course of debauchery, that few live beyond forty, and many do not attain their thirtieth year. From the pursuits of the females being productive to their parents, their marriages are deferred to a later period than is usual in India.

The females who do not attend the juggling exhibitions of the men, or their feats of activity, practise physic and cupping, and perform a kind of tattooing on the skin of the Hindus of their own sex, called *godna*. The men, besides their usual occupations, collect medicinal herbs, which are prepared by their wives as curatives, especially of the complaints of their own sex. In this manner, or by the sale of trinkets, they find employment in the towns, though these occupations afford them but a precarious subsistence. Some tribes also exhibit wild beasts to the vulgar, or offer for sale mats fabricated by themselves. Before the establishment of the British government in Bengal, the Bazeegurs were subject to the arbitrary exactions of a tax-gatherer, whom they greatly dreaded; and the apprehension of the renewal of that officer's powers has proved a considerable impediment to investigating their manners and customs.

The Bazeegurs are supposed to present many features analogous to the gipsies scattered over Europe and Asia, where they subsist as a distinct race from all the other inhabitants of the countries frequented by them. The Bazeegurs, as well as the gipsies, have a chief or king; each has a peculiar language, bearing some reciprocal analogy, and different from that of the people among whom they reside; and this analogy is so decided, that it is difficult to deny that in both cases it has had a common origin. Another resemblance, which has probably been lost in the lapse of time, is supposed to consist in the three-stringed viol introduced into Europe by the jugglers of the thirteenth century, which is exactly similar to the instrument now used in Hindustan. Disjoined, these analogies may not carry conviction of the identity of the European gipsies with the Indian Bazeegurs; but, on combining the whole, it does not seem unlikely, that if Asia be their original country, or if they have found their way from Egypt to India, they may also have emigrated farther at a period of remote antiquity, and reached the boundaries of Europe. (J.G.D.)

BAZGENDGES, the name of a substance used by the Turks and other Eastern nations in scarlet-dyeing.

BAZZANO, a city of Italy, in the papal delegation of Bologna, on the canal of St Giovanni. Pop. 2600.

BDELLIUM, a gum-resin of a dark-reddish colour, and bitter and pungent to the taste. It is used as a perfume, and sometimes in medicine as a weak deobstruent.

BEACHY-HEAD, a promontory on the coast of Sussex, between Hastings and Brighton, where the French defeated the English and Dutch fleet in 1690. It has a lighthouse with a revolving light 285 feet above high-water mark, in Long. 0. 13. E. Lat. 50. 44. N.

BEACON (Saxon *beacen*,) an ancient species of signal, consisting generally of a long pole to which was fastened a pitch-barrel to be fired by night, and to produce smoke by day. These were erected on conspicuous eminences, to give notice of an approaching invasion.

Beacons are also marks and signs erected on the coasts for guiding and preserving vessels at sea by night as well as by day. The erection of beacons, lighthouses, and sea-marks, is a branch of the royal prerogative. The sovereign has the exclusive power, by commission under the great seal, to cause them to be erected in fit and convenient places, as well upon the lands of the subject as upon the demesnes of the crown, which power is usually vested by letters-patent in the office of lord high admiral. By statute 8th Elizabeth, cap. 13, the corporation of the Trinity-house is empowered to set up any beacons or sea-marks wherever they shall think such necessary; and the owner of the land or any other person destroying these, or taking down any steeple, tree, or other known sea-mark, is declared liable to severe penalties.

BEACONAGE, money paid towards the maintenance of a beacon.

BEACONSFIELD, a market-town in the hundred of Burnham, county of Buckingham, 23 miles from London, on the road to Oxford. It consists of four streets crossing each other at right angles. This place is celebrated as the residence of the poet Waller and Edmund Burke; and both are buried here. Market-day Wednesday. Pop. in 1851, 1684.

BEAD, a small globule or ball used in necklaces, and made of different materials, as pearl, steel, garnet, coral, diamond, amber, crystal, pastes, glass. The Romanists make great use of beads in rehearsing their *Ave-Marias* and *Pater-nosters*; and a similar custom obtains among the religious orders throughout the East, as well Mahometan as heathen. A string of such beads is called a rosary.

Glass beads were used by the Spaniards to barter with the natives of South America for gold; and to this day they are a favourite article of traffic with all savage nations. Sir William Beechy made considerable use of them during his visit to Behring's Straits in 1828.

Bead-Proof, a term formerly used by distillers to denote that the spirit manufactured by them was of the legal strength. This was ascertained by immersing in the spirit Wilson's or Lovi's beads, which consisted of hollow balls or beads of glass so graduated that each would only maintain its equilibrium in a fluid of a certain density. The beads being all fitted for certain different densities, were thrown into the fluid to be tested, and the bead which was of the exact density of the fluid remained suspended in the fluid, the others sinking or floating according as the fluid was too dense or too thin for them. These beads are now quite superseded by Sykes's hydrometer. See Hydrodynamics.

Bead-Roll, among Roman Catholics, a list of persons for the rest of whose souls a certain number of prayers is to be repeated, which are counted by telling the beads.

BEADLE (from the Saxon *bydel*, or *bædel*, a messenger), a crier or messenger of a court, who cites persons to appear and answer. He is also called a *summoner* or *apparitor*. *Beadle* is likewise an officer of a university, whose chief business is to walk before the masters with a mace at all public processions. There are, besides, *church beadles*, whose business is to punish petty offenders.

BEAGLE (French, *bigle*), a small sort of hound or hunting dog. Beagles are of different kinds; as the southern beagle, something less and shorter but thicker than the deep-mouthed hound; the fleet northern or cat beagle, smaller and of a finer shape than the southern, and a harder runner. From these two, by crossing the strains, is bred a third sort, considered preferable to either. There is also a smaller sort, scarcely bigger than a lap-dog, which affords an agreeable diversion in hunting the rabbit or even the young hare in dry weather.

BEAK or Beak-head, that external part of a ship before the forecastle which is fastened to the stem and supported by the main-knee. The beak, called by the Greeks ἔμβολος, by the Latins *rostrum*, was an important part in the ancient ships of war, which were hence called *naves rostratæ*. The beak was made of wood, fortified with brass, and fastened to the prow, for the purpose of damaging the enemy's vessels. Its invention is attributed to Pisæus, an Etruscan. The first beaks were made long and high; but afterwards a Corinthian, named Ariston, made them short and strong, and placed so low as to pierce the enemy's vessels under water. By means of these great havoc was made by the Syracusans in the Athenian fleet. See Rostrum.

BEAKED, in *Heraldry*. When the beak and legs of a fowl are of a different tincture from the body, the technical expression is, *beaked and membered of such a tincture*.

BEALE, Mary, distinguished for her skill in painting, was the daughter of Mr Cradock, minister of Walton-upon-Thames, and is said to have learned the rudiments of the art from Sir Peter Lely. She painted in oil, in water-colours, and in crayons, and was greatly employed. Her portraits were executed in the Italian style, which she acquired by copying pictures and drawings from Sir Peter Lely's and the royal collections. She also imitated Vandyk. Her paintings have a good deal of nature, but the colouring is stiff and heavy. Her master, says Walpole, was supposed to have had a tender attachment to her, but as he was reserved in communicating to her all the resources of his pencil, it was probably a gallant rather than a successful one. Mrs Beale died in Pall Mall on the 28th December 1697, aged sixty-five.

BEAM, in weaving, a long thick wooden cylinder, placed lengthwise on the back part of the loom of those who work with a shuttle. That cylinder on which the stuff is rolled as it is weaved is also called the *beam* or *roller*, and is placed on the fore-part of the loom.

Beams of a Ship are the great main cross-timbers which hold the sides of the ship from falling together, and also support the deck and the orlops. The main beam is next the main-mast, and from it they are successively reckoned as first, second, third, and so on. The greatest beam of all is called the *midship beam*. A ship is said to be *on her beam-ends* when she inclines so much to one side that her beams approach to a vertical position.

Beam-Compass, an instrument consisting of a square wooden or brass beam, with sliding sockets that carry steel or pencil points. Beam-compasses are used for describing larger circles than can conveniently be drawn by the common compasses.

BEAMINSTER, or Beminster, a market-town in the parish of Netherbury, and county of Dorset. It is situated in a fruitful district surrounded with orchards, on the banks of the river Birt. It has some manufactures of sailcloth and other flaxen goods, coarse woollens, pottery, and tin, copper, and iron wares. Market-day Thursday. The town is well built, with a handsome church and free grammar-school. Pop. in 1851, 2085.

BEAN, the seed of certain leguminous plants cultivated for food all over the world, and furnished by three genera, *Faba*, *Phaseolus*, and *Dolichos*. The common bean, in all its varieties, as cultivated in this country and on the continents of Europe and America, is the produce of the *Faba vulgaris*. The French bean, kidney bean, or haricot, is the seed of the *Phaseolus vulgaris;* but in India several other species of this genus of plants are raised, and form no small portion of the diet of the inhabitants. From the genus *Dolichos*, again, the natives of India and South America procure beans or pulse, of no small importance as articles of diet, such as the *D. ensiformis*, or sword bean of India, the Lima beans, &c.; and two of the species *D. bulbosus* and *tetragonolobus* yield also tuberose roots, held in much estimation by the natives of India. These now form separate genera in modern botanical arrangements. The common bean is even more nutritious than wheat; containing 84 per cent. of nutritive matter, whereas wheat contains only 74 per cent. The principle use of beans is to feed horses, for which they are admirably adapted, as being far more nourishing than oats. In this country French beans are chiefly, almost exclusively, used in the green state, and the whole pod is eaten as a substitute for green peas. It is a wholesome and nutritious vegetable, and it is to be regretted that we do not follow the Dutch and Germans in preserving it for winter and spring use, when other green vegetables cannot be had. In Holland and Germany the pods of the French bean are preserved in salt by almost every family. The green pods are cut across obliquely, most generally by a machine invented for the purpose, and salted in barrels. In this state they keep the whole winter and spring. When wanted for use they are steeped in fresh water to remove the salt, and broiled or stewed, when they form an agreeable addition to the diet at a time when no other vegetable may be had. For the cultivation, &c., of the common bean, see Agriculture.

The ancients made use of beans in gathering the votes of the people, and for the election of magistrates. A white bean signified "absolution," and a black one "condemnation." Beans had a mysterious use in the *lemuralia* and *parentalia*, where the master of the family, after washing his hands three times, threw black beans over his head nine

Bean-Cod || Beard.

times, still repeating the words, "I redeem myself and family by these beans." Ovid gives a lively description of the whole ceremony. Abstinence from beans was enjoined by Pythagoras, one of whose symbols is κυάμων ἀπέχεσθαι, *abstinere a fabis*. The Egyptian priests held it a crime to look at beans, judging the very sight unclean: and among the Romans the *flamen dialis* was not permitted even to mention the name. The precept of Pythagoras has been variously interpreted. Some understand it to imply forbearing to meddle in trials and verdicts; others, resting on the equivoque of the word κύαμος, which signifies equally a *bean* and a human *testicle*, explain it by abstinence from venery. Clemens Alexandrinus grounds the prohibition against beans on their alleged quality of rendering women barren; and this is confirmed by Theophrastus, who asserts that some other plants have the same property. Cicero suggests another reason for this abstinence, namely, that beans are great enemies to tranquillity of mind. Hence Amphiaraus is said to have abstained from beans, even before Pythagoras, that he might enjoy a clearer divination by dreams.

Bean-Cod, a small fishing vessel, or pilot-boat, common in Portugal. It is extremely sharp forward, having its stem bent above into a great curve inward, plated on the fore-side with iron, and fortified with bolts. It is commonly navigated with a large lateen sail.

Bean-Fly, in *Natural History*, a very beautiful fly, of a pale purple colour, frequently found on bean-flowers. It is produced from the maggot called *mida*.

BEAR. See Mammalia, *Index*.

Bear, in *Astronomy*. See Ursa Major, and Astronomy.

Order of the Bear was a military order in Switzerland, instituted by the Emperor Frederick II. in 1213, by way of acknowledgment for the service the Swiss had done him, and in favour of the abbey of St Gall. To the collar of the order hung a medal, on which was represented a bear raised on an eminence of earth.

Bear or *Bere Island*, on the S.W. coast of Ireland, in Bantry Bay, is about six miles in length and one and a half broad. It lies twelve miles from Bantry, and is of a hilly and rugged aspect.

Bear Lake, *Great*, an extensive sheet of fresh water in the N.W. part of North America; between 65. and 67. N. Lat. and 117. and 123. W. Long. It is of a very irregular shape, and has an estimated area of 14,000 square miles. The Bear Lake River carries its waters into the Mackenzie River. It is upwards of 200 feet above the sea.

BEARD, the hair growing on the chin and adjacent parts of the adult male in the human subject.

Various have been the ceremonies and customs of nations in regard to the beard. The Tartars, from a religious principle, waged a long and bloody war with the Persians, declaring them infidels merely because they would not cut their whiskers after the fashion of Tartary; and we find that a considerable branch of the religion of the ancients consisted in the management of their beards. The Greeks wore their beards till the time of Alexander the Great; but that prince ordered the Macedonians to be shaved, lest the beard should afford a handle to their enemies. According to Varro and Pliny, the Romans did not begin to shave till the year B.C. 300, when P. Ticinius Mænas or Mæna brought barbers from Sicily.

Consecration of the beard was a ceremony among the Roman youth, who, when shaved for the first time, on assuming the *toga virilis*, kept a day of rejoicing, and were particularly careful to put the hair of their beard into a box, of silver or gold, and make an offering of it to some god, particularly to Jupiter Capitolinus, as was done by Nero, according to Suetonius.

The fashion of the beard has varied in different ages and countries; some cultivating one part of it, some another. The Hebrews wear a beard on the chin, but not on the upper lip or cheeks. Moses forbids them to cut off entirely the angle or extremity of their beard; that is, to manage it after the Egyptian fashion, leaving only a little tuft of beard at the extremity of the chin; whereas the Jews to this day suffer a little fillet of hair to grow from the lower end of their ears to their chins, where, as well as on their lower lips, their beards are in a pretty long bunch. The Jews, in time of mourning, neglected to trim their beards or cut off the superfluous growth on the upper lips and cheeks. In time of grief and great affliction they also plucked out the hair of their beards.

Beard.

Anointing the beard with unguents was an ancient practice both among the Jews and Romans, and still continues in use among the Turks. One of the principal ceremonies observed among the latter in serious visits, is to throw sweet-scented water on the beard of the visitant.

The discipline of the church has varied in the matter of beards. Ecclesiastics have sometimes been enjoined to wear them, from a notion of there being too much effeminacy in shaving, and that a long beard was more suitable to the ecclesiastical gravity; and sometimes again they have been forbidden to do so, from an idea that pride lurked beneath a venerable beard. The Greek and Roman churches have long differed on this important subject. Since the time of their separation, the Romanists seem to have given more into the practice of shaving by way of opposition to the Greeks; and have even made some express constitutions *de radendis barbis*. The Greeks, on the contrary, espouse very zealously the cause of long beards, and are extremely scandalized at the beardless images of saints in the Roman churches. By the statutes of some monasteries, it appears that the lay-monks were to let their beards grow, and the priests were enjoined to shave; and that the beards of all who were received into the monasteries were blessed with a great deal of ceremony. There are still extant the prayers used in consecrating the beard to God when an ecclesiastic was shaven.

Le Comte observes that the Chinese affect long beards extravagantly; but nature has balked them by only giving them a scanty growth, which however they cultivate with infinite care. Chrysostom observes that the kings of Persia had their beards woven or matted together with gold thread. The sculptures brought from Nineveh by Layard show the extreme care of their beards by that ancient race; and some of the first kings of France had their beards knotted and buttoned with gold.

Among the Turks, it is more infamous for any one to have his beard cut off, than among us to be publicly whipt or branded with a hot iron. The Arabs make the preservation of their beards a capital point of religion, because Mahomet never cut his. Hence the razor is never drawn over the face of the Sultan; and the Persians, who clip their beards and shave above the jaw, are reputed downright heretics. The slaves who serve in the seraglio have their beards shaven as a sign of their servitude.

The most celebrated ancient writers, and also some of later times, have spoken honourably of the fine beards of antiquity. Homer commemorates the white beard of Nestor, and that of old King Priam. Virgil describes that of Mezentius, which was so thick and long as to cover all his breast; and Chrysippus praises the noble beard of Timotheus, a famous player on the flute. Pliny the younger tells us of the white beard of Euphrates, a Syrian philosopher; and he takes pleasure in relating the respect and awe with which it inspired the people. Plutarch speaks of the long white beard of an old Laconian who on being asked why he let it grow to such length, replied, "It is that having my white beard continually before my eyes, I may do nothing unworthy of its whiteness." Strabo relates that the Indian philosophers called gymnosophists were particularly attentive to have their beards of sufficient length to "captivate"

Beard. the veneration of the people;—Diodorus gives a very circumstantial history of the beards of the Indians;—Juvenal does not forget that of Antilochus the son of Nestor;—Fenelon, in describing a priest of Apollo in all his magnificence, tells us that he had a white beard down to his girdle;—and Persius, convinced that a beard was the symbol of wisdom, thought he could not bestow a greater encomium on Socrates than by calling him the bearded master, *Magistrum barbatum.*

Whilst the Gauls were under the sway of their native sovereigns, none but the nobles and Christian priests were permitted to wear long beards. But the Franks, having made themselves masters of Gaul, assumed the same authority as the Romans; the bondmen were expressly commanded to shave their chins; and this law continued in force until the entire abolition of servitude in France. So, likewise, in the time of the first race of kings, a long beard was the sign of nobility and freedom; and the kings, as being the highest nobles in their kingdom, were emulous to display the largest beards. Eginhard, secretary to Charlemagne, speaking of the last kings of the first race, says they came to the assemblies in the field of Mars in a carriage drawn by oxen, and sat on the throne with their hair dishevelled, and a very long beard, *crine profuso, barba submissa, solio residerent, ut speciem dominantis effingerent.*

To touch any one's beard, or cut off a bit of it, was, among the early French, the most sacred pledge of protection and confidence. For a long time all letters that came from the sovereign had, for greater sanction, three hairs of his beard in the seal; and there is still in being a charter of 1121 which concludes with the following words: *Quod ut ratum et stabile perseveret in posterum, præsenti scripto sigilli mei robur apposui cum tribus pilis barbæ meæ.*

Several great men received or adopted the surname of *Bearded.* The Emperor Constantine IV. is distinguished by the epithet of *Pogoniates;*—in the time of the Crusades, we find there was a *Geoffrey the Bearded;*—Baldwin IV., Earl of Flanders, was surnamed *Handsome-Beard;*—and, in the illustrious house of Montmorenci there was a famous *Bouchard* who took a pride in the surname of *Bearded,* and was always the declared enemy of the monks, doubtless because they were shavelings.

In the tenth century, we find that King Robert of France, the rival of Charles the Simple, was not more famous for his exploits than for his long white beard. In order that it might be more conspicuous to the soldiers when he was in the field, he used to let it hang down outside his cuirass; and this venerable sight encouraged the troops in battle, and served to rally them when defeated. A celebrated painter in Germany, called John Mayo, had so large a beard that he was nicknamed *John the Bearded.* He wore it fastened to his girdle; and though he was a very tall man, it hung upon the ground when he stood upright. John would sometimes untie it in the presence of the Emperor Charles V., who took great pleasure in seeing the wind make it fly against the faces of the lords of his court. In England, the chancellor Sir Thomas More, one of the greatest men of his time, was able, when on the fatal scaffold, to procure respect for his beard, and saved it by a pleasantry. When he had laid his head on the block, he drew his beard aside, observing, "My beard has not been guilty of treason; it would be an injustice to punish it."

Every one has admired on medallions and in portraits the beard of the renowned Henry IV. of France, "which gave to the countenance of that prince a majestic dignity, and which ought to serve as a model for that of every great king, as the beard of his illustrious minister should for that of every statesman." But there is little dependence on the stability of the things of this world. By an event equally fatal and unforeseen, the beard, which had arrived at its highest degree of glory, all of a sudden lost its favour, and was at length entirely proscribed. The unexpected death of Henry the Great, and the youth of his successor, were the sole causes of this revolution. Louis XIII. mounted the throne of his glorious ancestors without a beard. Every one concluded immediately that the courtiers, seeing their young king with a smooth chin, would look upon their own as too rough; and the conjecture proved correct. They presently reduced their beards to whiskers, and a small tuft of hair under the nether lip. But the people at first refused to follow this dangerous example. The Duke of Sully also persisted in clinging to his beard. This man, great as a general and a minister, was likewise so in his retirement, and had the courage to keep his long beard, nay, to appear with it at the court of Louis XIII., when called thither to give his advice in an affair of importance. The young smooth-shaven courtiers laughed outright at the grave look and old fashioned appearance of the venerable minister; on which the latter, probably jealous of the honour of his beard, observed to the king, "Sir, when your father, of glorious memory, did me the honour to consult me on his great and important affairs, the first thing he did was to send away all the buffoons and stage-dancers of his court." Beard.

The Czar Peter had the boldness to impose a tax on the produce of his subjects' chins. He ordered that the noblemen and gentlemen, tradesmen and artisans, should pay a hundred rubles for the privilege of retaining their beards, and that the lower class of people should pay a copec for the same liberty; and he established clerks at the gates of the different towns to collect these duties. Such a new and singular impost troubled the vast empire of Muscovy, and both religion and manners were thought in imminent danger. But Peter was inflexible, and shaving began in good earnest; the Russians very generally coming to the conclusion that it was better to cut off their beards than to give serious offence to a man who had the power of cutting off their heads.

Example, more powerful than authority, produced in Spain what the Czar Peter had not accomplished in Russia without great difficulty. Philip V. ascended the throne with a shaven chin. The courtiers imitated the prince, and the people in turn imitated the courtiers. This revolution however, although brought about gradually, and without violence, caused much lamentation and murmuring; the gravity of the Spaniards lost by the change, and they said, *Desde que no hay barba, no hay mas alma;* "since we have lost our beards, we have lost our souls." In fact, among those European nations which have been most curious in beards and whiskers, we must distinguish Spain. This grave romantic people has always regarded the beard as an ornament which ought to be peculiarly prized, and indeed has often made the loss of honour consist in that of their whiskers. Nor have the Portuguese, whose national character is much the same, been behind them in this respect. In the reign of Catherine queen of Portugal, the brave John de Castro had taken the castle of Diu in India. Victorious, but in want of everything, he found himself obliged to ask the inhabitants of Goa to lend him a thousand pistoles for the maintenance of his fleet; and as a security for that sum he sent them one of his whiskers, telling them,—"All the gold in the world cannot equal the value of this natural ornament of my valour; and I deposit it in your hands as a security for the money." The whole town was penetrated with his heroism, and every one interested himself about this invaluable whisker: even the women were desirous to give marks of their zeal for so brave a man; several sold their bracelets to increase the sum asked for; and the inhabitants of Goa sent him immediately both the money and his whisker.

In Louis XIII.'s reign, whiskers (moustaches) attained the highest degree of favour, at the expense of the expiring

Bearing. beards. In those days of gallantry, not yet empoisoned by wit, they became the favourite occupation of lovers. A fine black mustachio, elegantly turned up, was a very powerful recommendation to the favour of the fair sex. They were still in fashion in the beginning of Louis XIV.'s reign; and this king, with all the great men of his time, took a pride in wearing them. They were consequently the ornament of Turenne, Condé, Colbert, Corneille, Molière, &c. It was then no uncommon thing for a favourite lover to have his moustaches turned up, combed, and dressed by his mistress; and hence a man of fashion took care to be always provided with every little necessary article, especially whisker-wax. It was highly flattering to a lady to have it in her power to praise the beauty of her lover's moustaches, which, far from being disagreeable, gave his person an air of vivacity; and several even thought them an incitement to love. But the levity of the French caused several changes both in their form and name; there were *Spanish, Turkish, guard-dagger* whiskers, nay, even *royal* ones, which were the last worn; the smallness of these proclaiming their approaching fall.

Kissing the BEARD. The Turkish wives kiss their husbands' beards, and children their fathers', as often as they come to salute them. The men kiss one another's beards reciprocally on both sides when they salute in the streets, or return from a journey.

Bearded Women. Of these there have been several remarkable instances. In the cabinet of curiosities of Stuttgard in Germany, there is the portrait of a woman called Bartel Grætje, whose chin is covered with a very large beard. Her portrait was painted in 1587, at which time she was only twenty-five years of age. It is said that the Duke of Saxony had the portrait taken of a poor Swiss woman, remarkable for her long bushy beard; and those who attended the carnival at Venice in 1726 saw a female dancer astonish the spectators not more by her talents than by her chin covered with a black bushy beard. Charles XII. had in his army a female grenadier, who had both the beard and courage of a man. She was taken prisoner at the battle of Pultowa, and carried to Petersburg, where she was presented to the Czar in 1724; her beard measured a yard and a half. A woman was once seen at Paris who had not only a bushy beard on her face, but her body likewise covered all over with hair. Amongst a number of examples of this nature, that of Margaret, the Governess of the Netherlands, is very remarkable. She had a very long stiff beard, on which she prided herself; and being persuaded that it contributed to give her an air of majesty, she took care not to lose a single hair of it. The Lombard women, it is said, when they went to war, made themselves beards with the hair of their heads, which they ingeniously arranged on their cheeks, in order that the enemy might take them for men.

Beard of a Comet, the rays which the comet emits towards that part of the heavens to which its proper motion seems to direct it, is distinguished from the tail, which denotes the rays emitted towards that part from which its motion appears to carry it.

BEARING, in *Navigation*, an arch of the horizon intercepted between the nearest meridian and any distant object, either discovered by the eye and referred to a point on the compass, or resulting from the spherical proportion; as, in the first case, "at four P.M. Cape Spado, in the isle of Candia, bore S. by W. by the compass." In the second, the longitudes and latitudes of any two places being given, and consequently the difference of latitude and longitude between them, the bearing of one from the other is discovered by the following analogy: As the meridional difference of latitude is to the difference of longitude, so is the radius to the tangent of the bearing.

BEARING is also the situation of any distant object estimated from some part of the ship according to her position. An object so discovered must be either ahead, astern, abreast, on the bow, or on the quarter. If the ship sails with a side wind, it alters in some measure the names of such bearings, since a distant object on the beam is then said to be to leeward or to windward; on the lee-quarter or bow, and on the weather-quarter or bow. Bearings ‖ Beatitude.

BEARINGS, in *Heraldry*, a term used to express a coat of arms.

BEAST, a general appellation given to all four-footed animals, fit either for food, labour, or sport.

BEAT, in the Manége. A horse is said *to beat the dust* when at each stroke or motion he does not take in ground or way enough with his fore-legs.

Beat of Drum, in the military art, is a succession of strokes, varied in different ways, for particular purposes; as, an alarm of sudden danger; a notice to repair immediately to arms or quarters; or an order to obey a movement either in advance or retreat. To *beat the tattoo*, is to give notice for retiring to quarters by a very rapid succession of strokes on the drum.

BEAT, *St*, a town of France, in the department of Upper Garonne, at the confluence of the Garonne and the Pique. It stands in a narrow ravine, which renders it gloomy. The houses are chiefly built of marble. Pop. 1400.

BEATERS. See GOLD-BEATERS.

BEATIFICATION, an act by which the pope declares a person beatified or blessed after his death. It is the first step towards canonization, or raising any one to the honour and dignity of a saint. The corpse and relics of the future saint are exposed to the veneration of all good Christians; his images are crowned with rays, and a particular office is set apart for him, but his body and relics are not carried in procession. Indulgences and remissions of sins are likewise granted on the day of his beatification.

BEATING THE WIND, was a practice in use in the ancient method of trial by combat. If one of the combatants did not appear in the field at the time appointed, the other was to make so many flourishes with his weapon, by which he was entitled to all the advantages of a conqueror.

Beating Time, in *Music*, a method of measuring and marking the time for performers in concert, by a motion of the hand or foot up and down successively and in equal times. The Romans had an officer called *portisculus* in each galley, whose business it was to beat time to the rowers by a pole or mallet, or by his voice alone. The ancients marked the rhythm in their musical compositions; but to make it more observable in practice, they beat the measure or time, and this in different manners. The most usual method consisted in a motion of the foot, which was raised from and struck alternately against the ground. This was commonly the province of the master of the music, called μεσόχορος and κορυφαῖος, because placed in the middle of the choir of musicians, and in an elevated situation, in order to be more easily seen and heard by the whole company. These beaters of measure were also called by the Greeks ποδοψόφοι, because of the noise of their feet; the Latins denominated them *pedarii, podarii*, and *pedicularii*. To make the beats or strokes more audible, their feet were generally shod with a sort of sandals made of wood or iron, called by the Grecks κρούπεζια, κρούπαλα, κρούπετα, and by the Latins *pedicula, scabella*, or *scabilla*, because resembling little stools or foot-stools. The ancients also beat time or measure with shells, as oyster shells, and bones of animals, which they struck against one another, in the manner of the modern castanets and similar instruments. Other noisy instruments, as drums, cymbals, and citterns, were also used for the same purpose.

BEATING, in *Navigation*, the operation of making progress at sea against the wind, by steering in a zigzag course.

BEATITUDE imports the supreme good, or the highest

Beaton || Beattie.

degree of happiness human nature is susceptible of; in other words, the most perfect state of a rational being, wherein the soul has attained to the utmost excellency and dignity it is capable of. In this sense it is equivalent to what we call "blessedness," or "sovereign felicity," the Greeks εὐδαιμονία, and the Latins *summum bonum*, *beatitudo*, and *beatitas*. Beatitude, in a theological sense, denotes the beatific vision, or the fruition of God in a future life to all eternity. This term is also used in speaking of the opening theses of Christ's sermon on the mount.

BEATON, DAVID (CARDINAL BEATON), archbishop of St Andrews, an eminent Scottish statesman and ecclesiastic, born in 1494. He was made a cardinal by Pope Paul III. in December 1538; and having been employed by James V. in negotiating his marriage at the court of France, he was there consecrated bishop of Mirepoix. Soon after his instalment as archbishop of St Andrews, he promoted a furious persecution of the reformers in Scotland; but the king's death put a stop for a time to his arbitrary proceedings. He was excluded from the management of public affairs, and thrown into confinement; but he soon raised so strong a party that, upon the coronation of the young Queen Mary, he was admitted of the council, made chancellor, and procured a legatine commission from the court of Rome. He now began to renew his persecution of heretics; and, amongst others, the famous Protestant preacher George Wishart suffered death at the stake in front of the cardinal's residence at St Andrews. It is alleged that Wishart, in the midst of the flames, foretold that Beaton would die a violent death; a prediction which probably proved the cause of its own fulfilment, as the persecutor was assassinated in his chamber, May 29, 1547. See SCOTLAND.

BEATTIE, JAMES, LL.D., a distinguished moralist and poet, was born on the 25th of October 1735, at Laurencekirk, then an obscure hamlet, in the county of Kincardine in Scotland; near which place his father rented a small farm. He received his early education at the common school of the parish, of which it is recorded that Ruddiman had been teacher about forty years before. His acquirements are said to have been interrupted at this time by want of books; a difficulty which has excited commiseration in more instances than that of Beattie, but which is so little able to control natural genius that it seems almost an incitement to its exertions; as "all impediments in fancy's course are motives to more fancy." He first became acquainted with English versification through Ogilby's translation of Virgil.

By his father's death he had been thrown, while yet of tender age, on the care of his elder brother, David Beattie; who, observing his natural endowments, afforded him, notwithstanding his own limited means, every aid in his power towards a liberal education, and in the year 1749 placed him at Marischal College, Aberdeen, where he soon afterwards obtained a bursary or exhibition. Here he had the advantage of pursuing his studies under Dr Thomas Blackwell, author of the *Life of Homer*, Dr Gerard, and other eminent men. In addition to his academical course, he began at this time to instruct himself in the Italian language, and appears to have had a strong predilection for Metastasio.

In 1753 he was appointed schoolmaster of Fordoun, a small village at the foot of the Grampian Mountains, where he likewise performed the duty of precentor or parish clerk, usually attached to that office in Scotland. Here he indulged the propensities of the youthful poet, and frequently wandered during a whole night in the fields, "chewing the cud of sweet and bitter fancy;" and it was from a height in this neighbourhood that his eye first caught a glimpse of the ocean. From the scenery of this secluded spot he appears to have derived, as might be expected, many of those images which he afterwards transferred into his poetical compositions; and certainly no exertion of the inventive powers can furnish representations equal to these immediate copies from nature. Such is that picture in the small poem which he calls *Retirement*

Beattie.

> "Thy shades, thy silence, now be mine,
> Thy charms my only theme;
> My haunt the hollow cliff whose pine
> Waves o'er the gloomy stream;
> Whence the scared owl on pinions gray
> Breaks from the rustling boughs,
> *And down the lone vale sails away*
> *To more profound repose.*"

Such also, among many others in the *Minstrel*, are those beautiful pictures contained in the 20th and 21st stanzas of the first canto.

In this secluded place Beattie was discovered and noticed by Mr Garden, afterwards Lord Gardenstown, then sheriff of the county, and by Lord Monboddo. In 1757 he became a candidate for the situation of usher in the grammar-school of Aberdeen. He was at this time foiled in the competition; but next year, on the occasion of a new vacancy, he was requested to accept the office. Lastly, he was removed, in 1760, to the professorship of Moral Philosophy and Logic in the Marischal College. Here he passed the remainder of his life, occupied in the zealous discharge of his professional duties, and in literary pursuits. Here, too, he possessed all the advantages of a congenial society in the company of Dr George Campbell, Dr Reid, Dr Gerard, and other celebrated men who then adorned the university of Aberdeen.

His first publication was a small collection entitled *Original Poems and Translations*, which was printed in 1760 or 1761. Of many of the pieces contained in this little volume he was afterwards ashamed, and not only omitted them in the subsequent selections which he published, but endeavoured, as far as possible, to obliterate all traces and recollection of them. Of these lesser pieces, *The Hermit* is best known; which, though it cannot be considered as a finished composition, is full of pathos and beauty. In *The Battle of the Pigmies and Cranes*, translated from the Latin of Addison, he has displayed a greater command of terse and happy expression than in most of his original pieces.

Beattie was married, in 1767, to Miss Mary Dun, daughter of Dr James Dun, rector of the grammar-school of Aberdeen. This connection, at first every way auspicious for his happiness, proved in the sequel a source of the deepest distress; for in the course of a few years Mrs Beattie, whose mother had laboured under a similar malady, showed unequivocal symptoms of mental disorder, which terminated in a state of confirmed insanity.

In the year 1770 Beattie published his *Essay on the Nature and Immutability of Truth in opposition to Sophistry and Scepticism*. His design was "to prove the universality and immutability of moral sentiment;" and his motives for the undertaking are sufficiently evident from the title which he has prefixed to the book. He appears to have been particularly encouraged to the prosecution of this task by the opinions of Dr John Gregory and Dr Blacklock. A general outline of the work, which appeared in most of the journals previously to its publication, was prepared by the latter. His original intention, as expressed by himself in one of his letters, was, "first, to have considered the permanency of truth in general;" and, secondly, to have applied the principles which he should have established "to the illustration of certain truths of morality and religion, to which the reasonings of Helvetius, of Mr Hume in his *Essays*, and of some other modern philosophers, seemed unfavourable." Of this plan the former part only was completed. It is well known that, in the execution of it, the author did not spare the opinions of those whom he considered the enemies of religious and moral truth, and particularly treated the

Beattie. writings of Hume without reserve or qualification. The friends of the latter took up arms in return, representing the *Essay* as a piece of personal and unprovoked hostility; and, some time after, the opinions which it contained were canvassed in a more public manner, and with much severity, in an *Examination* by Dr Priestley. These attacks or retaliations were met by Beattie with the same firmness which he had displayed in the original publication of his sentiments; nor would he ever consent to abate either the plainness or spirit with which he had expressed them.

In proportion to the censure which this publication called forth from a certain number of persons, was its favourable reception with a different class. It was the means of gaining for its author the unsolicited good offices of George Lord Lyttleton, Dr Johnson, Hurd bishop of Worcester, Percy bishop of Dromore, and many others. From the great success of the work, a second edition of it was called for in 1771. Beattie visited London in the same year, and again in 1773. On the last of these occasions he received some flattering marks of public notice and distinction. He had the honour of being admitted to a private and long interview with His Majesty; received from the university of Oxford an honorary degree of doctor of laws at the same time with Sir Joshua Reynolds; and was afterwards requested by the latter to sit for his portrait. The reputation of his *Essay*, and still more, perhaps, the motives and general character of the author, likewise procured for him about this time a yearly pension of L.200 from the crown.

In the course of the same year, 1773, he published the first part of his *Minstrel, or the Progress of Genius;* to which he added a second part in 1774. His object, as described by himself, was "to trace the progress of a poetical genius, born in a rude age, from the first dawning of fancy and reason till that period at which he may be supposed capable of appearing in the world as a minstrel; that is, as an itinerant poet and musician; a character which, according to the notion of our forefathers, was not only respectable but sacred." It appears from his letters that he little anticipated the favourable reception which this poem obtained from the public; a doubt which was probably founded on the want of incident and variety of character in the composition. Its merit, however, was quickly acknowledged; and by it the author's reputation as a poet and a man of genius was raised to its height.

On occasion of a vacancy which occurred soon after in the chair of natural and experimental philosophy at Edinburgh, it was proposed that Dr Beattie should become a candidate; to which step he was strongly urged by some of his friends, particularly Lord Hales; and about the same period he received various offers of preferment in the English church. These plans of promotion, however, he successively declined, considering the situation which he held as best adapted to his abilities, and affording him the greatest opportunities of usefulness. His reluctance to accept a chair in the university of Edinburgh arose partly, indeed, from the remaining effect of those heats which controversial metaphysics had produced. "I am so great a lover of peace," he says in a letter to one of his friends on this occasion, "and so willing to think well of my neighbours, that I do not wish to be connected with one person who dislikes me."

Between the years 1780 and 1793 he published his *Elements of Moral Science*, and various other works, moral and critical, which are well known, and deservedly popular. He enjoyed the acquaintance and friendship of many distinguished characters in different classes of society. Among his literary correspondents in England were Bishop Porteous, Mrs Montagu, Scott the poet of Amwell, and Gray. He was intrusted by the latter, in 1768, with superintending Beattie. an edition of his poems, printed by Foulis.

During the latter period of his life Dr Beattie experienced a new train of domestic calamities, which, added to the unfortunate situation of Mrs Beattie, gradually undermined his health and impaired his intellectual powers. The first and severest of these trials was the loss of his eldest son, James Hay Beattie, who died in 1790; in whose society he had found one of his greatest enjoyments, and who had already been associated with him in the professorship of moral philosophy, at the early age of nineteen.[1] Some years after, his only remaining son, Montagu Beattie, likewise died, after a short illness. This event he intimated to one of his friends, by a letter written on the same day, in the terms of calm and unaffected resignation. But his mind had been violently shaken even before this blow; and when he looked on the dead body of his son for the last time, he gave way to the scene, and exclaimed, "Now I have done with this world." Its first effect was the loss of memory respecting his deceased son. Yet it was found that, by the mention of what the latter had suffered during his sickness, his recollection could usually be recalled. He continued to discharge his duty as professor; but, notwithstanding some returns of a more vigorous intellect and fancy, he did not from this time resume his studies, and seldom answered the letters which he received. He was attacked with palsy in 1799, and afterwards sustained repeated shocks, the last in 1802. He lingered till the 18th of August 1803, when he expired at the age of sixty-eight. A particular account of his life and writings, by Sir William Forbes of Pitsligo, who had long been his friend and confidant, was published in 1806, in which are to be found some interesting selections from his private correspondence.

The character of Dr Beattie is delineated in his writings, of which the most prominent features are purity of sentiment, and warm attachment to the principles of religion and morality. His dispositions were gentle and modest, and he possessed great tenderness of heart. He was laborious in his literary pursuits, yet fond at all times of conversation and society. Towards the latter period of his life he was subject to an irritability of nerves, by which his temper was sensibly affected; and though, to appearance, his bodily frame was robust, he had impaired his strength by excessive study. He possessed considerable talents both for music and drawing.

His abilities as a writer may be said to have already undergone that ultimate test which is to be found in public opinion; and it has ranked him high as a moralist, a critic, and a poet. His *Essay on Truth* became a very popular book, particularly in England, and has gone through many editions. It must be confessed that this work is not without considerable faults as a philosophical composition. Its leading doctrine has been thus stated by himself: "As we know nothing of the eternal relations of things, *that* to us is and must be *truth* which we feel that we must believe; and *that* to us is falsehood which we feel that we must disbelieve. I have shown that all genuine reasoning does ultimately terminate in certain principles, which it is impossible to disbelieve, and as impossible to prove; that, therefore, the ultimate standard of truth to us is common sense, or that instinctive conviction into which all true reasoning does resolve itself." What constitutes the chief defect of the *Essay* is a want of that strictness and precision which a discussion of the metaphysical parts of the subject necessarily requires. His *Elements of Moral Science*, and his different critical and philological treatises, are compositions of a very pleasing character; and it was chiefly by them that his reputation was established in other countries. Some of his books were early translated into the Dutch and other languages. A French

[1] An interesting account of his life and character, by Dr Beattie, with a small collection of his compositions in prose and verse, was published in the year 1800.

Beaucaire ‖ Beauharnois.

translation of his *Essays on Poetry and Music* was printed at Paris in 1798. But it is chiefly as the author of the *Minstrel* that Beattie is known, and will continue to be admired. This poem, or rather poetical fragment, for the design was not completed, stands fully confirmed in the public favour. A single stanza may suffice to show the author's exquisite appreciation of the beauties of nature:—

"O, how canst thou renounce the boundless store
Of charms which Nature to her votary yields!
The warbling woodland, the resounding shore,
The pomp of groves, and garniture of fields;
All that the genial ray of morning gilds,
And all that echoes to the song of even,
All that the mountain's sheltering bosom shields,
And all the dread magnificence of heaven;—
O, how canst thou renounce, and hope to be forgiven!"

It has been objected to the second part of this poem that it contains too much philosophy. But, though the instruction conveyed in it be frequently addressed to the understanding, it is never abstruse, and the lessons are those of a poet not less than of a moralist. Like the *Castle of Indolence*, it is in scope and design a didactic piece. Both commence in the highest strain of descriptive and pathetic poetry; and the subsequent depression of tone in both is a necessary result of this lofty preparation. But the criticism is more just when applied to the work of Thomson than to the *Minstrel*.

The following is a list of Dr Beattie's writings: *Poems*, first published in 1760; *Essay on Truth*, 1771; *Minstrel*, 1771, 1774; *Essays*, viz., On Poetry and Music—On Laughter and Ludicrous Composition—On Classical Learning, 1776; *Dissertations*, viz., On Memory and Imagination—On Dreaming—On the Theory of Language—On Fable and Romance—On the Attachments of Kindred—and Illustrations of Sublimity, 1783; Evidences of Christianity, 1706; and Elements of Moral Science, 1790, 1793. He likewise published, in 1790, an edition of Mr Addison's papers in the *Tatler*, *Spectator*, *Guardian*, and *Freeholder*, and of his *Treatise on the Christian Religion*, with his *Life of Tickell*, and some original Notes, Edinburgh 4 vols. 8vo. (J. G—D.)

BEAUCAIRE, the ancient *Ugernum*, a town of France, department of Gard, and arrondissement of Nismes. Lat. 43. 48. 32. N. Long. 4. 38. 50. E. It is situated on the right bank of the Rhone, opposite Tarascon, with which it is connected by a magnificent suspension-bridge of four arches, and 1456 feet in length. The town is generally well built, but has no public buildings worthy of notice, and the streets are narrow and crooked. Its ancient castle is now in ruins. It gives name to the canal which communicates with the sea, and also connects it with the canal of Languedoc, forming part of the line of communication between the Rhone and the Garonne. It is also connected with Nismes and Alais by a railway opened in 1839. The manufactures are few and unimportant. The town derives its celebrity from the annual fair held here from the 1st to the 28th of July, and to which merchants come from all parts of Europe, and even from Persia and Armenia. An extensive meadow on the banks of the Rhone is set apart for the fair, which exhibits almost every kind of article, whether of convenience or luxury. Though now less frequented than formerly, it is said that still as many as 100,000 persons attend. Pop. of town in 1846, 8536.

BEAUFORT, Cardinal, son of John of Gaunt. See England.

Beaufort, a town of France, department of Maine and Loire, with a castle, sixteen miles E. of Angiers. Pop. 3000.

BEAUHARNOIS, Eugene, step-son of Napoleon, who treated him and his sister as children of his own. He was born in 1780, and in 1806 married the Princess Augusta Amelia of Bavaria. He was viceroy of the kingdom of Italy from 1805 to 1814. He accompanied Buonaparte in his Italian campaigns, and in Egypt; was with him in the disastrous Russian campaign of 1812–13; and after Napoleon and Murat left the army, the chief command devolved on Eugene, who had shown skill and courage during the retreat. He appears to have been an amiable and judicious man. After the overthrow of Napoleon in 1814, he withdrew to Munich, and died there in 1824, at the age of forty-five.

Beaulieu ‖ Beaumarchais.

BEAULIEU, Sébastien de Pontault de, a celebrated French engineer and field-marshal under Louis XIV. He published plans of all the military expeditions of his master, with military disquisitions annexed. He died in 1674.

BEAULY, a village of Scotland, county of Inverness, situated on the north side of the river Beauly, where it flows into the Moray Firth. On this river there is a fine cascade called the Falls of Kilmorack. Beauly has the remains of a Cistercian abbey, founded in the year 1230. The port is accessible to vessels of ninety tons burden. The trade carried on is inconsiderable. Distance west of Inverness, ten miles. Long. 4. 21. W. Lat. 57. 29. N.

BEAUMARCHAIS, Pierre Augustin Caron de, appears to have been one of those persons who, from restlessness of disposition and singularity of character, obtain, in their own age, more celebrity than they are entitled to from their merit or talents. He was born at Paris in 1732, and was the son of a clockmaker, who brought him up to his own trade. From his earliest youth, however, he discovered an inclination for literature, together with a remarkable talent for music. His proficiency in this art procured him an introduction to the French court, where he was employed to teach the princesses, daughters of Louis XV., to play on the guitar. At their concerts, which he attended, he became acquainted with the banker Duverney, by whom he was instructed in business, and placed in a situation which was likely to lead to fortune. Beaumarchais first attracted public attention by his drama of *Eugénie*, which was published in 1767; but he was chiefly indebted for the notoriety he obtained to the various law-suits in which he became involved after the death of his patron Duverney. The chief advantage which he acquired from these various processes was the astonishing interest and admiration which were universally excited in France by the *Factums* or *Memoires* which he wrote in his defence; in which the most logical and convincing argument is diversified with the bitterest sarcasm, the keenest raillery, and the relation of incidents as strange and amusing as any which are met with in romance. These able and lively productions, however, procured him many enemies, as they discovered him to be a man of a most resentful and calumnious disposition. Though occupied with these processes and various literary pursuits, Beaumarchais did not neglect the improvement of his fortune. He engaged in various speculations, of which the most profitable was his project of supplying the Americans with arms and ammunition during the war with this country. Having thus gained a considerable fortune, he built a magnificent villa in the Faubourg St Antoine, which he embellished with much taste and at great expense. He afterwards lost some part of the money he had acquired by an expensive and ill-executed edition of the works of Voltaire; and neither the early support which he gave to the principles of the French revolution, nor his importation of fire-arms for the use of the French forces, was sufficient to preserve his property from confiscation, or his person from proscription. The sufferings and dangers which he experienced during this period have been detailed by him in a work entitled *Mes Six Époques*, which is written with considerable force and interest. After he had endured every species of accusation and persecution, and had passed some time as an exile from his native country, he returned to France when the storms of the revolution had subsided into a more settled tyranny; and having recovered po[illegible]ion

Beaumaris || Beaumont and Fletcher.

of his villa in the Faubourg St Antoine, he remained there till his death, which happened suddenly in the year 1799.

Besides his *Mémoires*, Beaumarchais is the author of various dramatic productions, which made a great noise, and gained him considerable reputation in Paris at the time they appeared. His works were published at Paris in 1809, in 8 vols. 8vo; and in 1827, in 6 vols. 8vo. (W. H–Z–T.)

BEAUMARIS, a borough and market-town of Anglesey, North Wales. It is situated on the bay of Beaumaris, at the northern entrance of the Menai Straits, in Lat. 53. 16. N. Long. 4. 5. W. The town consists of several neat streets, and at the extremity of the principal one stands the castle. This fortress was built by Edward I. about 1295. It covers a great extent of ground, but its imposing effect is somewhat lessened by its low position, which was so designed that the fosse might communicate with the sea, so that vessels might unload beneath its walls. The chapel dedicated to the Virgin is a spacious structure containing several fine monuments. A free school was founded here in 1603. The principal buildings are the town-hall, county-hall, prison, custom-house, assembly-room, and national school. Beaumaris has no manufactures, but is much frequented as a bathing-place. The corporation consists of a mayor, four aldermen, and nine councillors. It unites with Holyhead, Amlwch, and Llangefni, in returning a member to parliament. Market-day Saturday. The bay affords good anchorage, having seven fathoms of water at the lowest ebb. Pop. in 1851, 2599.

BEAUMONT, Sir George Howland, the seventh baronet of a family in Leicestershire, was a distinguished amateur of the fine arts, and an excellent landscape painter. He was a munificent contributor to the National Gallery, and to that of Dulwich. He was born in 1753, and died in 1827.

Beaumont, *Sir John*, the elder brother of Francis Beaumont the famous dramatic poet, was born in the year 1582, and in 1626 had the dignity of baronet conferred upon him by Charles I. In his youth he applied himself to poetry with tolerable success, and wrote *The Crown of Thorns*, a poem, in eight books; a miscellany, entitled *Bosworth Field;* Translations from the Latin poets; and several poems on religious and political subjects. He died in 1628. His poetic genius was celebrated by Ben Jonson, Michael Drayton, and others.

Beaumont and Fletcher, two celebrated English dramatic writers, who flourished in the reign of James I., and were so closely connected, both as authors and as friends, that it has been judged not improper to give them under one article.

Francis Beaumont was descended from an ancient family at Grace-Dieu, in Leicestershire, where he was born about the year 1585 or 1586, in the reign of Queen Elizabeth. His grandfather, John Beaumont, was Master of the Rolls, and his father, Francis Beaumont, one of the judges of the Common Pleas. He was educated at Cambridge, and afterwards admitted of the Inner Temple. It does not, however, appear that he made any great proficiency in the law, a study which may be presumed to have been too dry and unentertaining for a man of his fertile and sprightly genius. Indeed we should scarcely be surprised to find that he had given no application to any study but poetry, nor attended on any court but that of the Muses: our attention might rather fix itself on the opposite extreme, and fill us with admiration of the extreme assiduity of his genius and rapidity of pen, when we consider the voluminousness of his works, and the brief space allowed him for their composition; works, the execution of which might well have occupied a long life. For although, out of fifty-three plays which are collected together as the joint labours of these brother-authors, Beaumont was concerned in much the greater part, yet he did not live to complete his thirtieth year. He died in the beginning of March 1616, on the ninth day of which he was interred in the entrance of St Benedict's Chapel, in Westminster Abbey. There is no inscription on his tomb; but there are two epitaphs to his memory, one by his elder brother Sir John Beaumont, and the other by Bishop Corbet. He left a daughter, Frances Beaumont, who died in Leicestershire some time after the year 1700. She had in her possession several poems of her father's composition; but these were lost at sea in a voyage from Ireland, where she had lived for some time in the Duke of Ormond's family.

Beaumont and Fletcher.

John Fletcher was not more meanly descended than his poetical associate; his father, the Rev. Dr Fletcher, having first been made bishop of Bristol by Queen Elizabeth, and afterwards by the same princess, in the year 1593, translated to the rich see of London. The poet was born in 1576; and, like his friend, was educated at Cambridge, where he made great proficiency in his studies, and was accounted a very good scholar. A natural vivacity of wit, for which he was remarkable, soon rendered him a devotee of the Muses; and his close attention to their service, and fortunate connection with a genius equal to his own, soon raised him to one of the highest places in the temple of poetical fame. As he was born near ten years before Beaumont, so also he survived him by an equal period; the plague, which broke out in the year 1625, having carried him off in the forty-ninth year of his age.
